property can readily be demonstrated in the lymphatics of the peritoneal surface of the diaphragm. If a suspension of graphite is injected into the peritoneal cavity of a rabbit, the subperitoneal lymphatics can be seen filled with the black material. Red cells, too, can be removed by this route from the peritoneal cavity in considerable numbers; and F. C. Courtice, J. Harding and A. W. Steinbeck showed that they reach the blood stream through the right lymph duct. There appears to be a slow steady movement of cells from the blood stream through the tissues and into the lymphatics. The precise significance of this is not clear.

The high degree of permeability of the lymphatic endothelium has a further consequence in that substances of low molecular weight which have been absorbed by lymph capillaries may, during their passage along these channels, diffuse out again into the surrounding tissue fluid to be reabsorbed by the blood vessels or by other lymphatics. An interesting observation on the permeability of lymphatic vessels to diffusible substances was made by M. R. Lewis. If histamine or adrenaline is inserted into the skin by puncture, some of the substance is taken up into the lymphatics, but leakage out again into the tissue fluid occurs during passage up the lymphatics, as is shown by the occurrence of a reddish line of dilated capillaries and venules in the case of histamine, and a white line due to the contraction of these vessels in the case of adrenaline.

8. Propulsion of Lymph.—Lymph hearts (that is, organs for pumping lymph through the lymphatic vessels) are not present in mammals. Rhythmical contraction of lymphatic vessels has occasionally been noted (e.g., in the mesenteric lymph vessels of the rat and guinea pig), but, in the main, the propulsion of lymph in mammals is due to extrinsic and not intrinsic forces. In the first place, the slight tissue pressure helps to drive fluid from the tissue spaces into the lymphatic capillaries. Though the head of pressure is not great (in the mouse's ear 1.9 cm. of water outside the lymphatic capillary, 1.2 cm. in its lumen), it exerts a continual effect, augmented by movement. All the larger and most of the smaller lymphatic trunks are liberally supplied with valves, which consist usually of two cusps and which permit the flow of lymph in one direction only, namely toward the heart. In the limbs, movement and muscular contraction are the main propelling agents. If a cannula is inserted into a lymph trunk in a limb, no lymph flows if the limb is at rest, but there is considerable flow if it is either massaged or made to move, whether actively or passively. In the intestine, contraction squeezes out lymph very effectively into the cisterna chyli and the thoracic duct. This can be shown readily by observing the great increase in thoracic duct lymph flow after the administration of drugs such as pilocarpine which stimulate peristalsis. Once lymph has found its way into the cisterna chyli (see fig. 2), the pressure changes associated with each inspiration—namely, increased intra-abdominal pressure expelling it from the abdomen, and negative intrathoracic pressure sucking it into the thorax and great veins—form the final link in the chain of extrinsic propelling agents.

In some situations, an additional aid to lymph flow may be the transmitted pulsation from adjacent arteries; e.g., the aorta and the thoracic duct. Occasionally, the lymph vessels may even form plexuses around the arteries.

9. Pressure in Tissue Spaces.—The relation between the tissue pressure and that within the lymphatic capillaries raises the problem of the patency of these vessels, which might be expected to collapse if the pressure of the fluid outside them were greater than that inside. This might conceivably be an even more difficult problem when the tissue pressure is increased as in cases of edema. It was long ago observed, however, by W. A. Gaskell that fibres passed from the walls of the lymphatic vessels into the surrounding tissues in the epiglottis, so that if the tissues became swollen with fluid, these fibres were pulled on and helped to keep open the lumen of the vessel to which they were attached. These observations later were confirmed by B. D. Pullinger and H. W. Florey in experimentally induced edema in the ear of the mouse, in which fine argyrophilic connective tissue fibres could be demonstrated passing from the walls of widely patent lymph capillaries into the surrounding edematous tissues.

II. LYMPHOID COMPLEX, LYMPHOID ORGANS AND LYMPHOID TISSUES

The second great component of the lymphatic system consists of the lymphoid complex, a group of organs and tissues formed by: (1) lymph nodes; (2) subepithelial lymphoid tissues, lying under the mucous membrane of the alimentary canal; (3) the spleen; (4) the thymus; and (5) hemolymph nodes. In addition, there are large numbers of lymphocytes scattered throughout the connective tissues, especially abundant in the bone marrow.

1. Total Amount of Lymphoid Tissue.—It is difficult to assess the total amount of lymphoid tissue in the body, and the method which has been employed, namely the careful dissection and weighing of all the scattered lymphoid masses, is far from ideal. E. Andreasen estimated that in young adult rats the total amount of lymphoid tissue, including the thymus, is 0.5%–1% of the body weight.

2. Age Changes.—Lymphoid tissue undergoes age changes. Well developed until puberty, when it reaches its maximum, it then undergoes atrophy. In old age the thymus and subepithelial lymphoid tissues have for the most part disappeared, but the spleen and lymph nodes persist.

3. Relation Between Different Members of the Lymphoid Complex.—Though all members of the lymphoid complex are referred to as lymphoid tissue, there are marked points of difference. In the case of the thymus, it has been questioned whether it really is a lymphoid organ, and it has been suggested that though the thymic cells bear a superficial resemblance to lymphocytes they do in fact form a distinct cell species. However, thymocytes and lymphocytes both have the same characteristic movement, the nucleus forming a rounded head, the cytoplasm a short stumpy tail.

There are significant differences between the members of the lymphoid complex in the ability to form antibodies. The spleen can, when required, produce large amounts of antibody, the thymus none, while the lymph nodes are intermediate in this respect.

4. Lymph Nodes.—Lymph nodes or lymph glands are the most numerous of all the lymphoid organs. They are pink bodies situated on the course of the lymphatics and they therefore possess both entering (afferent) and draining (efferent) lymph vessels. They are rounded or bean-shaped (see fig. 3) and vary in size from small nodules to flattened masses perhaps two inches long, large nodes being commonest in the groin. Each node has a fibrous capsule from which trabeculae pass toward the interior, where they break up and interlace to form a network, the intervals being filled by lymph sinuses and cell columns. Beneath the capsule of the node is a peripheral lymph sinus into which the afferent lymphatic vessels enter, usually from the convexity of the node. Subsidiary lymph sinuses traverse the node from the peripheral sinuses

BY COURTESY OF W. B. SAUNDERS AND CO.

FIG. 3.—LYMPH NODE

and are collected together at the hilus (where the blood vessels enter) as one or more efferent lymphatic trunks. The node is subdivided by the internal lymph sinuses and trabeculae into rounded nodules of lymphoid tissue in the cortical region and elongated cords in the medullary region. In the centre of each cortical nodule there may be a lighter area of large cells, the germ centre, while considerable regions may be occupied by diffuse lymphoid tissue without any nodules. The complete endothelial lining of the entering lymphatic vessels is not continued to line the sinuses of the node, which are rather spaces in the reticular tissue, often traversed by fine bridgelike strands of reticulum, to which adhere many large, flattened, reticulo-endothelial cells. These latter cells, in contrast to the lymphocytes, are highly phagocytic and readily take up foreign particles which enter by the lymph. Thus the thoracic nodes of city dwellers are black from carbon strained off in its passage from the lungs. In a similar way, invading bacteria which have been taken up by the lymphatics tend to be arrested in the nodes draining the affected region.

The exact position of the various groups of lymph nodes is very important from a medical point of view. The tendency for an infection to spread to the draining lymph nodes just mentioned is a case in point. Another is the tendency of malignant tumours to spread and involve the lymph nodes. It is not possible here to describe in detail the positions of the nodes and groups of nodes. Full descriptions are given in treatises on anatomy.

Besides being adapted to filtering off foreign particles, the slow seepage of the lymph through the node permits easy entry of cells from the node into the lymph. Indeed, lymphocytes that are formed in the node and then enter the lymph as it traverses the node are an important source of the free lymphocytes of the blood. Lymphocyte formation can occur in diffuse lymphoid tissue even in the absence of germinal centres, but the latter seem to develop whenever maximal production of lymphocytes is required.

Lymph nodes reach their highest development in mammals. Simpler nodes are present in marsupials. Among the birds only certain aquatic species possess them, but they are of very simple structure and are present only in certain situations; viz., a pair at the thoracic inlet and a similar pair in the abdomen. In some birds there are quite appreciable accumulations of lymphoid tissue in the walls of blood vessels. In fishes and amphibia lymphoid tissue does not occur by itself, but is found in the lympho-myeloid organs, where it is closely associated with tissue which forms myelocytes, granulocytes and erythrocytes.

5. Subepithelial Lymphoid Tissues.—The subepithelial lymphoid tissues lie under, and in close association with, the mucous membrane of certain parts of the alimentary canal. At the upper end are situated the palatine tonsils, the nasopharyngeal tonsils (known as adenoids when enlarged) and the lingual tonsil, which lies posteriorly on the dorsum of the tongue. These three sets of tonsils thus form a group surrounding the entrance to the pharynx. Throughout the intestine there occur solitary nodules, but they are most numerous in the small intestine, in the terminal part of which they also form large aggregations known as Peyer's patches. The submucosa of the appendix is closely packed with lymphoid tissue. The subepithelial lymphoid tissues have a simpler type of organization than lymph nodes. As they have no afferent lymph vessels and therefore no lymph sinuses traversing them, the subepithelial lymphoid tissues consist of lymphoid nodules with germ centres and a variable amount of diffuse lymphoid tissue, surrounded by a network of lymphatic capillaries.

6. Lymphoid Tissue in the Spleen.—The spleen is enclosed in a capsule which is muscular and contractile in many animals, but in man is mainly fibroelastic. From the capsule trabeculae ramify throughout the organ, forming a framework the meshes of which are occupied by the splenic pulp. The latter is of two types, the white pulp, which is composed of lymphoid tissue as described above, and the red pulp. This consists of venous sinuses among which are a spongy network of cells, the splenic cords, containing lymphocytes and numerous macrophages, either free or arranged as a network (the pulp reticulum). On the cut surface of the organ the white pulp is visible as rounded or elongated gray areas up to one millimetre in diameter, sometimes known as the

Malpighian bodies, and usually surrounding the arteries. No lymphatic channels are present in the pulp, which possesses instead a highly specialized blood vascular arrangement which allows intimate contact of the cellular and fluid elements of the blood with the lymphoid and reticulo-endothelial cells of the pulp. This permits the spleen, quite apart from its reservoir function, to entrap foreign particles circulating in the blood stream in the same fashion as a lymph node arrests particles in the lymph stream. (See also SPLEEN.)

7. Thymus.—The thymus, situated in man behind the upper end of the sternum, consists of a dense mass of round cells embedded in a reticular framework. Draining lymphatics are present, but entering lymphatics are not. Besides the small round cells or thymocytes, groups of epitheliallike cells (Hassall's corpuscles) are present. Controversy still exists as to whether the thymus is a true lymphoid organ, for in some ways it reacts differently from lymphoid tissues elsewhere, though the differences are usually of degree rather than of kind. On the whole, the available evidence appears to favour the view that the thymocyte and the small lymphocyte are identical; in tissue culture they both show the same type of distinctive movement. The thymocytes tend to be the smallest of the small lymphocytes, with a bare minimum of cytoplasm, resembling most closely the small lymphocytes in bone marrow. The evidence suggests that the thymus is the most vigorous cell producer of all the lymphoid organs, being four to six times as active as lymph node tissue. (See also THYMUS.)

8. Hemolymph Nodes.—These bodies are similar to simple lymph nodes but their sinuses contain blood. They are most conspicuous in ruminants such as the sheep. In man they are found only within the abdomen and are of very small size and minor physiological importance. They are in all probability lymph nodes whose afferent lymph vessels have contained an abnormally large number of erythrocytes, which then accumulate in the sinuses of the nodes.

9. Lymphoid Tissue in Bone Marrow.—Certain aspects of this question are considered in the discussion below on the fate of the lymphocyte. Here it need only be noted that mammalian bone marrow does not normally contain organized lymphoid tissue of the type associated with lymphocyte production in all other situations. It may contain scattered small lymphocytic aggregates, and it usually has a large number of small lymphocytes, which seem not to have been formed in the marrow but to have entered it from the blood.

10. Functions of Lymphoid Tissue.—Two main functions have been assigned to lymphoid tissue: (1) defense and (2) lymphocyte formation. The defense theory was originated by R. Virchow, who maintained that noxious particles entering the lymph stream were held up in the sinuses of the nodes. This simple barrier theory was later extended to include antibody production. The view that lymphocyte production is an important function of lymphoid tissue received a strong impetus from the observation by W. Flemming (1885) that the germinal centres contained abundant mitoses.

III. LYMPHOCYTES

Lymphocytes are often described in terms of size as large, medium or small, though there are other differences associated with these size relationships. The most numerous cell type—and also still the centre of acute controversy—is the small lymphocyte. In fresh wet preparations of blood or lymph the small lymphocytes are rounded cells, usually about eight microns in diameter. The nucleus almost fills the cell and is round, oval or bean-shaped. If kept at body temperature the lymphocytes move about rapidly for short periods, and then round off to a resting state in which small pseudopodia may form and retract. The movement is distinctive, since the nucleus forms a rounded head and the cytoplasm the tail. The number of moving cells increases from the first to the ninth hour, by which time most of the cells are moving. This is in contrast to the behaviour of the polymorphs, which are most active initially but are almost rounded and inactive after six hours.

The cytoplasm of the lymphocyte is clear, and mitochondria can be seen in unstained cells. In fixed preparations treated with

Romanowsky stains the nucleus of the lymphocyte is coloured an intense dark purple, while the cytoplasm is a clear pale blue, though in the large lymphocytes it may be much more basophilic. Ultraviolet absorption studies indicate that the nucleus of the small lymphocyte contains the diploid number of chromosomes.

1. Genetic Relations of Lymphocytes.—Lymphocytes develop either from other lymphocytes or from nonlymphocytic precursors in the various lymphoid tissues, but the details of their origin and development are matters of dispute, as part of the larger question of the origin and interrelationships of blood cells generally. M. M. Wintrobe (1946) emphasized that one of the main points of disagreement between the proponents of the various general theories of blood formation is in regard to what constitutes a lymphocyte. With regard to developmental potentialities, the question has been most acute in relation to the small lymphocyte.

It has been maintained on the one hand that the small lymphocyte is totipotent, capable of developing into all the other cells of the blood and connective tissue, and on the other hand, that it is incapable of further development; intermediate views have been held. If the small lymphocyte is totipotent, then it must be regarded as a specialized form of the primitive mesenchymal cell, reduced to the smallest possible size to facilitate rapid mobilization and transport through the blood stream from one part of the body to another.

2. Production of Lymphocytes and Entry Into Blood.—The study of lymphocyte production is beset with many difficulties. Newly formed lymphocytes may enter the blood indirectly, by first entering the lymph stream, or directly, by passing through the walls of the blood capillaries in lymphoid tissue. The indirect entry lymphocytes reach the blood by the thoracic duct, the right lymph duct or other and irregular lymphatic-venous communications. In the past, it was assumed that most of the lymphocytes enter the blood by way of the thoracic duct, and numerous quantitative studies have been based upon this assumption. In a typical experiment, samples of lymph are collected at intervals from the thoracic duct over a period of several hours. Then from the total volume of lymph flow, and the number of lymphocytes per unit volume, it can readily be calculated that the number of lymphocytes entering the blood stream a day by this route alone is considerably in excess of the total number of lymphocytes in the blood. Since there is no clear evidence that lymphocytes are destroyed while in the blood, it must be assumed either that there is a continuous circulation of lymphocytes between blood and lymph, or that the lymphocytes leave the blood stream and are continually replaced by the newly formed cells which are entering it. J. M. Yoffey (1936) estimated that in the dog the blood lymphocytes were replaced about $2\frac{1}{2}$ times a day, and termed this the daily replacement factor (D.R.F.). A. G. Sanders, H. W. Florey and J. M. Barnes found in the rabbit a D.R.F. of about five; and in general, the smaller the animal the higher the D.R.F. Studies of cell multiplication in the lymphoid tissues themselves suggest that lymphocyte formation may be considerably more active than the thoracic duct data indicate. As to the relative contribution of the different members of the lymphoid complex, it is probable that the thymus is the most active of all the lymphocytopoietic tissues and that the intestinal and mesenteric lymphoid masses rank next in importance.

3. Fate of the Lymphocytes.—H. S. Sjövall (1936) maintained that the lymphocytes continually recirculated between blood and lymph, and experiments involving prolonged drainage of thoracic duct lymphocytes have been interpreted as supporting this view. It is, however, difficult to reconcile this with the active synthesis of deoxyribonucleic acids (DNA) in lymphoid tissues. The existence of a very rapid turnover for lymphocytes poses acutely the question of the fate of these cells. It is unlikely that lymphocytes undergo degeneration on any considerable scale while in the blood stream. It is also improbable that there are large numbers of lymphocytes lost to the body by migration through the epithelium of the intestine, though a certain number may be.

Lymphocytes are constantly migrating into the connective tissues, but there is no evidence to prove that this extravascular migration occurs on a sufficiently large scale to account for the

"disappearance" of the lymphocytes. Another suggestion is that the lymphocytes are filtered out of the blood into the bone marrow. This concept would fit in admirably with the view that lymphocytes are totipotent and capable of developing into the other blood cells, but on this point there is no general measure of agreement. From a quantitative point of view, it is significant that very large numbers of lymphocytes occur in normal marrow and all the evidence points to their reaching the marrow from the blood. The number of lymphocytes present in the marrow is more than adequate to account for the numbers daily disappearing from the blood.

The question of the transformation of lymphocytes into other cells has been extensively investigated not only in the tissues of the organism but also in living organisms by the technique of tissue culture. Some observers have claimed that starting with pure cultures of lymphocytes they have noted the subsequent appearance of monocytes, macrophages, fibroblasts, granulocytes and erythroid cells. But their claims have not met with general acceptance.

4. Function of the Lymphocyte.—It has long been widely held that the lymphocyte plays a part in the defense mechanisms of the body. Many familiar observations form the basis for this belief, among them the increase in the blood lymphocytes in many infectious diseases; the accumulation of lymphocytes around areas of subacute or chronic inflammation, especially when due to organisms such as those of syphilis and tuberculosis; the mantle of lymphocytes around an invading tumour; and the collections of lymphocytes in parts subjected to mechanical or chemical irritation. The anatomical arrangement of the masses of lymphoid tissue has been advanced as support for the protective role of the lymphocyte. Thus the tonsillar ring of lymphoid tissue is often described as guarding the gateway to the alimentary canal from the entry of organisms; a similar protective function is assigned to the lymphoid nodules of the intestine, while the disposition of lymph nodes as filters along the course of the lymph stream has given further support to these views.

Direct factual evidence has become available about the role of the lymphocyte in these defense processes. The small lymphocyte lacks phagocytic powers and is incapable of producing antibodies to bacteria or foreign proteins. In 1935 P. D. McMaster and S. Hudack, following up earlier work, demonstrated specific agglutinins in the lymph nodes draining an infected area, though they were unable to show which cells were responsible. W. E. Ehrlich and T. N. Harris (1942) found that the injection of antigen into the pad of a rabbit's foot was followed by a hyperplasia of the popliteal node, with an increase in the cell count and the antibody content of the lymph issuing from a cannula inserted into the efferent lymphatic. But subsequent work led Ehrlich and his collaborators to the view put forward by A. Fagraeus (1948) and others, that it was the plasma cell which was in the main responsible for antibody formation, not the lymphocyte. A. Coons and his co-workers applied an ingenious technique involving the use of fluorescent antigen and antibody, as a result of which they showed not only that it is not the small lymphocyte in lymph nodes which is responsible for antibody formation, but that the plasma cells which are responsible are derived from the primitive reticular cells and large lymphocytes from which small lymphocytes also arise.

The part played by the reticulo-endothelial cells is not altogether clear. F. R. Sabin (1939) used a coloured antigen to study antibody production, and suggested that this process occurred in the phagocytic cells of the reticulo-endothelial system which ingested the antigen. It was later shown that antigen was indeed retained for 11 weeks and longer in the macrophages of lymphoid organs, even though these cells were not in themselves responsible for antibody formation. It would appear, therefore, that when antigen reaches a lymph node it is taken up mainly by the reticulo-endothelial cells, and that subsequently the node reacts by producing increased numbers of both plasma cells and lymphocytes. The plasma cells remain in the node and are a source of antibody; the lymphocytes are discharged in the efferent lymph and enter the blood. When the antigenic stimulation is at an end the formation

of plasma cells ceases and lymphocytopoiesis becomes once again the dominant activity. Antibody formation proceeds most actively in the spleen, to a lesser extent in lymph nodes, and seems to be completely absent in the thymus. (See IMMUNITY AND IMMUNIZATION.)

5. Lymphoid Tissue and Virus Infections.—In the case of virus infections, lymph nodes may constitute a mechanism for the dissemination of virus particles. Viruses are cytotropic, and when from a focus of infection they enter the lymphatics and come to the regional lymph nodes, they obtain access to the various cells, including the lymphocytes. When virus-containing lymphocytes leave the node they take virus with them to the blood stream, and so it becomes rapidly disseminated through the body. This mechanism of virus transport was first shown in the case of vaccinia. Viruses such as those of poliomyelitis were long thought to be exclusively neurotropic in their spread, but there is an increasing body of evidence to suggest that even with these viruses the lymphoid mode of dissemination may occur.

6. Lymphoid Tissue and the Endocrine System.—There exists only scanty information about the mechanisms by which the growth of lymphoid tissue is controlled. A good deal of attention has been directed toward the possibility of lymphoid tissue's being controlled through the endocrine system, more especially the adrenal glands. From the time when Thomas Addison (1855) first noted a lymphoid tissue hyperplasia in one of the 11 cases on which he based his description of the disease named after him, evidence has steadily accumulated to indicate a close connection between lymphoid tissue and the adrenal cortex. H. Selye (1937), in his first account of the adaptation syndrome, emphasized the role of the pituitary in stimulating the secretion of the adrenal cortex with resultant atrophy of the thymus. T. F. Dougherty and A. White in 1944 attributed an important role to the pituitary adrenotropic hormone in the regulation not only of the lymphocytes but also of the other cellular elements of the blood.

IV. DISEASES OF THE LYMPHATIC SYSTEM

A distinction must be drawn between, on the one hand, those conditions which primarily affect the lymphatic system, and, on the other, the reactions of the lymphatic system to disease of some other system or systems. Important in the latter connection is the role of the lymphatic system in edema and in the dissemination of tumours or bacteria. For information on these topics see CANCER; EDEMA; etc.

1. Lymphadenitis.—This disease, an inflammatory infection of lymph nodes, is characterized by hyperemia of, and exudation into, the lymph node, which becomes firmer, redder and enlarged. Three varieties may be distinguished: simple, suppurative and tuberculous. The cause is the arrest in the node of toxic or infective material, usually of viral or bacterial origin. This may occur in several of the acute infectious diseases, notably scarlet fever, diphtheria and German measles; and the infectious material may reach the lymph nodes either through the lymphatic vessels or from the blood stream. The lymph nodes of the neck are often enlarged, especially in children when chronic infection is present in the tonsils. In chronic infectious diseases such as syphilis and typhoid fever, many groups of nodes may be involved. Simple lymphadenitis usually subsides of its own accord if viral in origin, but it may progress to suppuration if the causal agent is pyogenic.

2. Tuberculous Lymphadenitis.—This is due to infection of the lymph nodes with the tubercle bacillus. Involvement of the draining nodes in this way is apt to follow tuberculous disease in any situation, as there is a particular tendency for the organisms to spread by the lymphatics. Thus, in pulmonary tuberculosis, the bronchial and mediastinal nodes are commonly involved in the process. Especially in young children, these nodes may become massively enlarged, even when the primary focus in the lung itself is small. In the neck there may be extensive involvement of many nodes with no obvious primary focus. In this case, although the matter has been considerably disputed, there is a good deal of evidence pointing to the tonsil as a common portal of entry. Tuberculous disease is also not uncommon in the mesenteric

lymph nodes. In this instance, the infection is from swallowed organisms. A sufferer from pulmonary tuberculosis may swallow some of his infected sputum instead of expectorating it, and so set up an intestinal and mesenteric infection. More important, however, is the abdominal tuberculosis resulting as a primary infection in children from the ingestion of milk from tuberculous cows.

The earliest manifestations of tuberculous lymphadenitis are an enlargement of the node and the formation within it of minute tubercles. It is possible in this stage for spontaneous healing to occur, but the disease often progresses to caseation, in which death of the tissue occurs and is followed by conversion of the dead material into a cheesy mass. This latter stage may end in calcification, but often the caseous material softens, so that the node may become a single abscess cavity. If left to itself, the "cold abscess" (as it is called) sooner or later penetrates the capsule of the node into the surrounding connective tissues, where it may track for some distance. In disease of the cervical nodes, the abscess may penetrate the skin at one or several points, through which the caseous contents are discharged. In diseases of internal nodes such as the mediastinal, the abscess may ulcerate into a blood vessel, with a resulting general dissemination of the disease. (See also TUBERCULOSIS.)

3. Lymphangitis.—In cases where an infective agent such as a hemolytic streptococcus is very virulent, there may be seen thin red lines in the skin tracking from the focus of infection (which may be quite trivial) toward the nearest group of lymph nodes. These lines indicate the spread of the organisms up the superficial lymphatics. The draining node may arrest the process, but in very severe cases localization of the infection may not occur, and organisms will then enter the blood stream.

4. Filarial Infestation: Elephantiasis.—A chronic lymphangitis occurs in filarial infestation. The adult worms, both male and female, live in the lymphatics, commonly those of the lower abdomen, pelvis or groin. The young microfilariae pass into the blood stream. The presence of the adult parasites in the lymphatic trunks causes obstruction, peripheral dilatation and irritation of the vessels. In certain cases the condition of elephantiasis may then supervene, possibly as a result of superadded infection. In the majority of such cases a lower limb is the part affected. (See also FILARIASIS.)

5. Reticulosis.—Mention has already been made of the diverse types of cells which are present in lymphoid tissue. It is not surprising therefore that primary diseases of this tissue should present, as in fact they do present, a bewildering variety of appearances and behaviour. Particularly is this the case in the hyperplastic conditions, and especially so in neoplastic (tumorous) conditions, where there is often a marked tendency for the cells of the tumour to revert to more primitive types. In such a confusing group of diseases classification is difficult and at the best only provisional. Where knowledge is scanty, definite opinions cannot be expressed. Nevertheless, the term reticulosis, or reticulo-endotheliosis, has been introduced by pathologists to include any systematized overgrowth of lympho-reticular tissue, whether neoplastic or nonneoplastic. Included in this category are Hodgkin's disease (lymphadenoma), lymphosarcoma, reticulosarcoma, leukemia, the generalized lipoidosis, as well as the systematized lymphadenitis seen in syphilis, kala azar, malaria and typhoid fever.

6. Hodgkin's Disease (Lymphadenoma).—This disease, fully described by Thomas Hodgkin in 1832, is characterized by a progressive enlargement of the lymph nodes all over the body, generally starting in the nodes of the neck. The majority of cases occur in young adult males. The first sign is usually the enlargement of a node in the neck, followed by progressive growth of the nodes in the submaxillary region and axilla. The inguinal group is early involved, and the abdominal nodes later. The swellings are at first painless, but in the later stages of the disease symptoms occur as a result of pressure on surrounding organs. When the disease starts in the deeper groups of nodes, the first symptom may be pain in the chest and cough, or pain in the abdomen, or pain and edema in the legs. For a long time the nodes remain dis-

crete and rubbery, but in the latter stages of the disease they may become matted together. In the majority of cases the spleen enlarges. Secondary anemia is common, slight irregular fever may be present; and eventually a great and progressive emaciation takes place.

The course of the disease advances slowly and is ultimately fatal. In the early stages, treatment may cause rapid decrease in the size of the masses, but when the nodes have become fibrotic there is little response.

Microscopic examination of the nodes shows a gradual replacement of the normal architecture of the lymphoid tissue by larger cells of various types, including giant cells with several nuclei. Areas of necrosis often occur. There is a marked and characteristic increase of reticulum (shown by silver staining) and, in the later stages of the disease, of dense fibrous tissue, which may almost obliterate the proliferating cells. (See also HODGKIN'S DISEASE.)

7. Lympho-Sarcoma.—This group comprises frankly malignant tumours of various types, including (among many others) those formerly classed as "lymphosarcoma" and the so-called "Hodgkin's sarcoma." They are, in general, more rapidly fatal than is Hodgkin's disease, and present a great variety of appearances and behaviour, in keeping with the multiple potentialities of the cell of origin (a relatively undifferentiated reticulo-endothelial cell) and the higher degree of malignancy. Although rare exceptions have been reported, overflow of the malignant cells from the lymphoid tissues into the blood stream does not occur, a feature which serves to distinguish these affections from leukemia.

8. Leukemia.—There are two main types of leukemia, namely, lymphatic and myelogenous. Lymphatic leukemia affects the lymph nodes most obviously, though it has been suggested that it may begin in the thymus. Myeloid leukemia is primarily a disease of the bone marrow, in which the enlargement of the lymph nodes is a secondary phenomenon due to the infiltration of the nodes by the proliferating myeloid cells. In chronic lymphatic leukemia the lymph nodes, liver and spleen become greatly enlarged, owing to the accumulation of great numbers of lymphocytes. In contradistinction to Hodgkin's disease, the nodes do not remain discrete, but soon become matted together. In addition, there is usually a great increase in the circulating lymphocytes of the blood, a phenomenon which does not occur in Hodgkin's disease or reticulo-sarcoma. More rarely the condition is acute, and in these cases the primitive lymphoblasts may be present in the blood, although the lymph nodes are only slightly enlarged. Death may occur in a few weeks in such cases.

The outcome of leukemia is inevitably fatal, after a long or short course, depending mainly on the acuteness of the process. Treatment directed to the bone marrow and lymphoid organs may arrest the process for a time.

LYMPHOGRANULOMA VENEREUM, a venereally acquired virus infection of lymph channels and nodes which may be manifested by ulcerations, rectal strictures and enlargement of lymph nodes and the genitalia. See VENEREAL DISEASES.

LYNBROOK, a village in Nassau county, on Long Island, N.Y., U.S., about 2 mi. E. of the New York city line. Primarily a residential community, Lynbrook also has light industry including electronic supplies, plastic buttons, hats, laboratory supplies and several mail order houses. The village was incorporated in 1911. For comparative population figures see table in NEW YORK: Population. (M. H. LE.)

LYNCH, BENITO (1885–1951), Argentinean novelist and short-story writer, whose works examine the psychology of uncomplicated persons at everyday activities, was born in Buenos Aires in 1885, of Irish ancestry. From his second until his tenth year he lived on a cattle ranch in the province of Buenos Aires, gaining an intimate knowledge of rural life. Being of independent means, he preferred later to live quietly and do his writing in La Plata. He died in Buenos Aires on Dec. 23, 1951.

Lynch's first important novel, *Los caranchos de la Florida* (1916), although somewhat melodramatic, opened a modern phase of the gaucho novel in Argentina. In the major novels *Raquel* (1918), *El inglés de los güesos* (1924)—generally considered his best work—and *El romance de un gaucho* (1933), he gives a unique interpretation of country folk in Argentina, diverging from the usual dramatic or sensational myth of the gaucho and using a simple, ironic style. His art is intuitive rather than intellectual, and his general approach is that of realism. Lynch's skill in shorter forms is best shown in the novelette *El antojo de la patrona* (1925) and the stories in *De los campos porteños* (1931).

See Arturo Torres-Rioseco, *Grandes novelistas de la América Hispana*, vol. i (1941). (A. CN)

LYNCHBURG, a city adjacent to but independent of, Campbell county in central Virginia, U.S., is located on the James river in the foothills of the Blue Ridge, 50 mi. E.N.E. of Roanoke. It was settled largely by Quakers in 1757 at a ferry established by John Lynch, after whom it was named. Despite its steep hills, it became a tobacco market of importance. Hogsheads of tobacco were rolled in from surrounding fields, lowered by ropes to the river below, and poled in flatboats to the tidewater at Richmond. Strict attention to grading made Lynchburg famous for its dark-leaf tobacco, which, flavoured with licorice, became a favourite chewing tobacco throughout the south.

The village was incorporated as a town in 1805, and by 1829 had grown into a bustling place of 4,630 inhabitants, with warehouses and stores. The importance of Lynchburg was enhanced by the construction of the James river canal in 1840 which enabled horse-drawn barges and packets loaded with freight and passengers to move between the town and Richmond. Canal traffic was gradually replaced by railroad transport in the 1850s. The town was incorporated as a city in 1852.

During the American Civil War it was an important Confederate supply base and link in communication between besieged Richmond and the west. After the war Lynchburg boomed. It acquired additional railroad connections and increased in population to 19,000 by the end of the 19th century. The city developed into a shoe and iron manufacturing centre and, although the change in smoking taste from dark to bright tobacco in the form of cigarettes shifted the centre of tobacco growing away from the red clay soils surrounding Lynchburg, the city continued to grow moderately, acquiring textile mills, garment factories and tool shops. Manufactures include drugs and cosmetics, hosiery, batteries, machine gears and steel products. Lynchburg was the home of Jubal Anderson Early, famous Confederate general, and John W. Daniel, orator and senator, and was the birthplace of Carter Glass, Samuel Untermyer and Robert L. Owen, authors of the Federal Reserve act (1913). It is the seat of Lynchburg college (affiliated with Christian Church and chartered 1903 as Virginia Christian college); Randolph-Macon Woman's college (Methodist, 1891) and Virginia Theological seminary and college (Negro, 1888). Sweet Briar college for women (private, 1901) is 11 mi. N.N.E. *Etude*, the music publication, was founded there by Theodore Presser in 1883. The Lynchburg Little Theatre dates from 1920.

The city adopted the council-manager form of municipal government in 1920. Pop. (1960) 54,790; standard metropolitan statistical area (Lynchburg city and Amherst and Campbell counties), 110,701. For comparative population figures see table in VIRGINIA: Population. (F. B. S.)

LYNCHING AND LYNCH LAW are terms loosely used to designate various forms of mob violence peculiar to the United States from the middle of the 18th century. The mob executes the offender, often also torturing him and mutilating his body, without

trial and regardless of existing courts of law, under the pretense of administering justice. The origin of the terms is uncertain, but the commonly accepted explanation is that they derive from Charles Lynch, a Virginia farmer and patriot, who, during the American Revolution, headed an irregular organization formed to punish thieves, outlaws and Tories. (See Thomas Walker Page, "The Real Judge Lynch," in *Atlantic Monthly*, vol. lxxviii [Dec. 1901].) The legal definition of lynching varies from state to state; but it includes the execution, without due process of law by three or more persons, of an individual suspected or convicted of a crime, or accused of an offense contrary to prevailing custom. Some states require that the lynch victim must have been in the hands of a peace officer before being seized by the mob.

The summary killing of an individual by a mob as a penalty for real or supposed crime has been practiced in all countries where unsettled conditions prevailed; and informal organizations of people have attempted to supplement or replace legal procedure by dealing with criminals outside the law. Hence American lynching is sometimes compared to such historic forms of private administration of criminal justice as the *Vehmgericht* in medieval Germany, the gibbet law and Cowper justice of border districts in England, the Jedburgh justice in Scotland, and the *Santa Hermandad* in Spain. Likewise the pogroms of Russia and Poland, and the treatment of Jews in Germany under Hitler in more modern times, are somewhat similar to lynching practices.

The English colonists in America were not slow to follow the old world practice of taking the law into their own hands, and mob law prevailed in the colonies prior to the Revolution. Examples are to be found in the extralegal organizations to punish Indian scalpers in New England; in the Rangers of Pennsylvania; in the Regulators of New York and North Carolina; and in the popular tribunals organized during the Revolution to mete out speedy punishment to robbers, bandits and Loyalists. Development of civil institutions did not keep pace with the westward expansion of population after independence had been gained, and the frontiersmen established agencies outside the law to deal with horse thieves, gamblers, murderers and others who violated generally accepted standards of conduct. The region beyond the Appalachian mountains furnished many examples of lynch law. Frontiersmen demanded immediate and personal justice. They were impatient of legal forms and technicalities, and they chose to take the law in their own hands. The extralegal governments of the state of Franklin and the Oconee republic, and the extralegal organizations of Squatters associations in the midwest and vigilantes of California and the Rocky Mountain frontier played an important role in the development of the great west. But the disregard of law and order fostered by frontier conditions carried over into mob violence and lynching long after the frontier stage of society had ended.

Conditions in the southern states also fostered a lawless spirit. Frontier conditions persisted until after the Civil War, but far more significant was the prevalence of slavery and a growing sectional bitterness over the institution. Southerners exercised their absolute control over slave property by flogging even to death their refractory slaves. Later they resorted to mob violence with increasing frequency and severity against persons accused of tampering with slavery. Vigilance committees flogged, tarred and feathered and hanged abolition agitators and persons accused of aiding fugitive slaves. After the Civil War, southerners organized the Ku Klux Klan, the Order of the White Camellia and similar bodies which molested and frightened the former slaves out of the exercise of their civil rights and lynched untold numbers of Negroes. These practices carried over into the later south as did frontier practices in the west. But the south and the west held no monopoly on lynching. Only Massachusetts, New Hampshire, Rhode Island and Vermont have a clean record in this respect.

The victims of western lynchings were largely white men, although a few Negroes were lynched, and the major offenses with which they were charged were murder and crimes against property. In the south lynching crystallized into a traditional method of summarily punishing Negroes accused of offenses,

chiefly murder and rape, against whites. Some few whites were lynched in the south, and occasionally Negroes lynched white men.

Fairly reliable data on lynchings are available since 1882. Compiled largely at Tuskegee institute in Alabama and published in the annual *Negro Year Book*, these data show that, between 1882 and 1951, 4,730 persons were lynched in the United States. Of these 1,293 were whites and 3,437 were Negroes. The crimes charged against the victims were: homicide 41%, rape and attempted rape 25.3%, robbery and theft 4.9%, felonious assault 4.3%, insult to whites 1.8%, and all others 22.7%. Between 1882 and 1901 the largest number lynched in any one year was 230, the smallest number 96; and between 1902 and 1935 the largest number lynched in any one year was 99, the smallest number was 8.

After 1935 the number of lynchings drastically declined. During the 1950s and early 1960s the average stood at less than one per year. Some years saw no lynchings at all. The character of lynch mobs also changed: mobs became more secretive; there were few spectacular man hunts; and mob leaders no longer boasted that they served race, tradition and justice.

Chief among the agencies effecting the decline were the National Association for the Advancement of Colored People, the Southern Commission on Interracial Cooperation, the Association of Southern Women for the Prevention of Lynching, and the Southern Regional Council. Individual journalists and educational and religious leaders, both white and Negro, also played a prominent role in the movement. They worked to elevate the economic and social position of the Negro and to improve relations between whites and Negroes. They emphasized the harmful consequences of lynching in debasing the reputation of the south, in brutalizing those who participate in lynchings, and in the general disrespect for law, order and human rights which lynchings tend to develop. All the southern states as well as several in the north and west enacted legislation looking toward the punishment of those who participate in mob violence and lynchings.

LYNDHURST, JOHN SINGLETON COPLEY, 1ST BARON (1772–1863), lord chancellor of England, was born at Boston, Mass., on May 21, 1772, the son of John Singleton Copley, the painter. He was educated at an English private school and at Cambridge university, where he was second wrangler and fellow of Trinity college. Called to the bar at Lincoln's Inn in 1804, he gained a considerable practice and was raised to the dignity of serjeant-at-law in 1813. As one of the counsel for James Watson, tried in 1817 for his share in the Spa Fields riot, he so distinguished himself as to attract the attention of the Tory government, under whose patronage he entered parliament as member for Yarmouth, Isle of Wight. Later he sat for Ashburton (1818–26) and for Cambridge university (1826–27). He was appointed king's serjeant and chief justice of Chester in 1818, solicitor general in 1819 (with a knighthood), attorney general in 1824, master of the rolls in 1826, and lord chancellor in April 1827 (in George Canning's ministry), with the title of Lord Lyndhurst. In this latter capacity he was particularly acceptable to George IV on account of his anti-Catholic views; but in 1829 he supported the government's Catholic relief bill.

During this period it was unusual for the lord chancellor to retire on a change of government, unless it was a "total" change, as in 1806 and 1830. Lord Lyndhurst, the supremely successful careerist of his time, would have welcomed an invitation to remain in office under Lord Grey in Nov. 1830. However, political necessity compelled the Whigs to appoint Henry Brougham, and although Lyndhurst was made lord chief baron of the exchequer (1831–34), this did not prevent him from vigorously opposing the Whig reform bill. He was again lord chancellor in Sir Robert

Peel's brief administration of 1834-35. During Lord Melbourne's ministry (1835-41) he figured conspicuously as an obstructionist in the house of lords. In these years it was a frequent practice with him, before each prorogation of parliament, to entertain the house with a "review of the session," in which he mercilessly attacked the Whig government. His former adversary Lord Brougham, disgusted at his treatment by the Whig leaders, soon became his most powerful ally in opposition, and the two dominated the house of lords. In the Peel administration of 1841-46 he resumed the office of lord chancellor for the last time. As Peel never had much confidence in Lord Lyndhurst, the latter did not exert so great an influence in the cabinet as his position and experience entitled him to do. But he continued a loyal member of the Tory party. He died in London on Oct. 12, 1863.

Of Lord Lyndhurst as a judge opinions have differed; there is authority, including Lord Selborne himself, for the view that he was not a just chancery judge. His heart was not in the business. But the qualities of a just chancellor in those days were of a very special order, and in the house of lords he was more at home, though the estimate must stand that he was "a judge for the parties rather than a judge for the lawyers." His greatest moment in the house of lords was his success in averting what would have been a disastrous precedent—the attempt of lay members to vote in an appeal to the house of lords, theoretically permissible but a violation of a strict constitutional understanding (Daniel O'Connell's case, Sept. 4, 1844).

(A. AL.)

LYNDSAY, SIR DAVID (c. 1485-c. 1555), Scottish poet and author of *Ane Satyre of the Thrie Estaitis*, the only surviving Scots morality play, was the son of David Lyndsay of the Mount, near Cupar (q.v.), Fife, and of Garmylton in East Lothian. He may have been at St. Andrews c. 1508. Entering the service of James IV, he became usher to the infant prince born in 1512, and married Janet Douglas, a court seamstress, c. 1522. Dismissed from court in 1524, when his charge, now James V, fell under the control of the Douglas faction, he returned to the king's service four years later. He acted as chief herald from c. 1530, and became Lyon king of arms in 1542. His duties took him on several missions overseas. In 1531 he accompanied a Scottish ambassador to Flanders, in 1536 he went with the royal envoys to France to negotiate a marriage alliance and after James's death in 1542 he went to the courts of Henry VIII, Charles V and Francis I, to return orders conferred on his master. Little is known of his last years. Most of his verse, with a work on heraldry, was written during his prosperous years at court. It survives as follows:

1. *The Dreame*; 1,134 ll. (?1528) is a vision of John Commonwealth and the ill-condition of Scotland, written in an old tradition, with a delightfully personal epistle to the king. This is his earliest surviving, though probably not his first, work in verse; he reminds James of the many stories he had "done discryve" for him in the nursery.

2. *The Testament and Complaynt of Our Soverane Lordis Papyngo* (completed Dec. 1530; stanzaic, 1,185 ll.) is a mixture of satire, comedy and moral instruction. The king's parrot, dying, gives advice to king and court and makes its testament. This poem again illustrates Lyndsay's preoccupation with mutability and with the corruption of the commonweal. The prologue contains a valuable catalogue of Scots poets.

3. *An Answer quhilk Schir David Lyndsay maid to the Kingis Flyting* (?1536) is a short and ribald example of the satirical genre best illustrated by William Dunbar (q.v.) and Walter Kennedy and apparently popular at court. James V's contribution has not survived.

4. *The Complaynt and Publick Confessioun of the Kingis Auld Hound callit Bagsche* (c. 1536) is a short didactic piece, satirizing court life through the mouth of the dog—a device used by Dunbar and others and revived by Robert Burns.

5. *The Deploration of the Deith of Quene Magdalene* (1537).

6. *The Justing betuix James Watsoun and Jhone Barbour*

Servitouris to King James the Fyft is a burlesque description of a jousting said to have been part of James's wedding celebration in 1538, again in a traditional mode.

7. *Kitteis Confessioun* and (8) *Ane Supplicatioun directit to the Kingis Grace in Contemptioun of Syde Tailis*, both of uncertain date, are short satires in couplets. The first is an attack, in a comic framework, on the confessional; the second calls for the abolition of the absurdly long trains then in fashion among women.

9. *The Tragedie of the Cardinall* (1547) is a rather tedious piece of moralizing on the pattern of Boccaccio's *De casibus virorum illustrium* (434 ll.).

10. *The Historie of Ane Nobill and Vailyeand Squyer, William Meldrum* (written after 1550) is a vigorous tale of love and war, celebrating, in the romance tradition, the heroic life of a Fifeshire laird (1,594 ll. in 8-syllable couplets), with a pendant fictitious testament (36 stanzas). This is the liveliest and most nearly nondidactic of Lyndsay's poems, and the last and most original of Scottish romances.

11. *Ane Dialog betuix Experience and ane Courteour of the Miserabyll Estait of the World* (?1553; 6,333 ll.), commonly known as the *Monarchie*, is a universal history from the Creation to the fifth (papal) empire, with a view of the last judgment, in four books. Stanzaic complaints are inset in the couplet narrative. The matter of the poem is drawn mainly from such authors as Josephus and Orosius, and is its only attraction. The style is flat, and the solemnity of tone is seldom relieved.

12. *Ane Satyre of the Thrie Estaitis* is the only complete Scots morality play to survive. It began as an interlude of "the mysdemeanours of Busshops Religious persones and preists within the Realme," written for the feast of the Epiphany at Linlithgow palace in 1540. Enlarged, with a deal of coarse comedy, it was performed at Cupar, Fife, on June 7, 1552; and again on the slopes of the Calton hill, Edinburgh, on Aug. 12, 1552, before the queen regent "and ane greit part of the Nobilitie . . . fra .ix. houris afoir none, till vi. houris at euin." It is a dramatic representation of the crucial issues of the mid-century in religion, government and social life, with all Scotland crowded on the stage. Some of the long didactic speeches are nobly rhetorical; the comic passages are written in a strong, colloquial Scots. There is something here for every class of society; each is mirrored, admonished and entertained. Lyndsay draws freely from a range of poetic genres: sermon, farce, debate, satirical "character," and song. The perennial interest and power of the *Satyre* was revealed by the brilliant revival at the Edinburgh festival of 1948.

BIBLIOGRAPHY.—*Manuscripts:* *Ane Dialog* survives in a manuscript at Lambeth palace, London; the Bannatyne manuscript (1568), in the National Library of Scotland, contains the "banns" and the "merry Interludis" of the version of the *Satyre* performed at Cupar; *The Register of Arms* (1542; published 1821, 1878), an authoritative document on Scottish heraldry, in the National Library of Scotland.

Editions: Most minor pieces were included in the Paris (1558) or Edinburgh (1559, 1568) editions; the *Papyngo* was first published in London in 1538 (there may have been an earlier edition), *Ane Dreame* at St. Andrews (1554), *The Historie of Squyer Meldrum* at Edinburgh (1582; earliest surviving edition, 1592) and *Ane Satyre* at Edinburgh (1602); H. Charteris published a collected edition at Edinburgh (1589). The first critical editions are by F. Hall, J. Small and J. A. H. Murray for the Early English Text Society, 5 parts (1865-71), and by D. Laing, 2 vol. (1871); 3 vol. (1879). The standard edition is by D. Hamer, for the Scottish Text Society, 4 vol. (1931-36). Modern editions of single works are *Ane Satyre of the Thrie Estaitis*, by J. Kinsley (1954), with a critical discussion by A. M. Mackenzie and an account of the 1948 revival by I. Brown; *The Historie of Squyer Meldrum*, by J. Kinsley (1959), with critical discussions.

Critical Works and Special Studies: A. J. Mill, "The Influence of Continental Drama on Lyndsay's Satyre," *The Modern Language Review*, xxv (1930); R. A. Houk, "Versions of Lyndsay's Satyre," *Publications of the Modern Language Association of America*, lv (1940); E. S. Miller, "The Christening of the Three Estates," *Modern Language Notes*, lx (1945); C. S. Lewis, in *English Literature in the Sixteenth Century* (1954); *Scottish Poetry: A Critical Survey*, ed. by J. Kinsley (1955). J. Kinsley, "Lyndsay's Satyre and the Modern Theatre," *The Saltire Review*, iv: 12 (1957). For a full account of Lyndsay's life and work see D. Hamer's Scottish Text Society edition. W. Murison's *Sir David Lyndsay* (1938) is a short general study. For a scholarly account of the complicated bibliography of the poems, see D. Hamer, *The Library*, x (1929). (J. KY.)

LYNEDOCH, THOMAS GRAHAM, 1ST BARON (1748–1843), British soldier who fought throughout the French Revolutionary and Napoleonic wars and became second-in-command to the duke of Wellington in Spain. He was born on Oct. 19, 1748, the son of Thomas Graham, laird of Balgowan. Until the outbreak of war with France in 1793 he lived the life of a country gentleman, traveling much on the continent, partly for the health of his wife, the beautiful Mrs. Graham of Gainsborough's famous portrait. While her body was being shipped home for burial after her death at sea off France in 1792, a revolutionary mob insisted on opening the coffin in search of hidden arms. In his resentment Graham became an inveterate foe of France. He served as a volunteer in Admiral Hood's fleet at the siege of Toulon (1793) and returned home to raise a Perthshire battalion, the 90th Foot. He saw service in the Quiberon expedition (1795), and as British military commissioner with the Austrian army in Italy (1796) he made a daring escape from Mantua to inform the relieving force of the critical position of its Austrian garrison. He returned to England after the peace of Amiens (1802) to take up his parliamentary duties as member for Perthshire.

On the renewal of war Graham rejoined the army. He served on Sir John Moore's staff in Sweden (1808) and in the Corunna campaign (1808–09), where he was present at Moore's death and burial. Graham was then promoted major general (1810) and given command of a force in southern Spain, where he won a brilliant but barren victory at Barrosa near Cádiz (1811). He then joined Wellington's army as commander of the 1st division. He commanded the left wing of the army in the advance to Vitoria and in Wellington's decisive victory there (1813). He then conducted the siege of San Sebastian. In 1814 he was transferred to command the British forces in Holland, but failed in an attempt to surprise the fortress of Bergen op Zoom, the last episode of his military career. He was created Baron Lynedoch in May 1814 and died in London on Dec. 18, 1843.

LYNEN, FEODOR (1911–), German biochemist who was awarded the 1964 Nobel Prize for Medicine jointly with Konrad Bloch (*q.v.*) for work on the metabolism of cholesterol and fatty acids, was born in Munich on April 6, 1911. He obtained his doctorate at the University of Munich in 1937 and qualified as university lecturer in 1941. In 1947 he became professor of biochemistry at Munich and in 1954 was named director of the Max Planck Institute of Biochemistry there.

Lynen was the first to isolate activated acetate, from which both cholesterol (*q.v.*) and fatty acids (*see* CARBOXYLIC ACIDS) are formed. With collaborators he unraveled the mechanism of fatty acid degradation in the so-called fatty acid cycle; and elucidated the pathway of biosynthesis of polyisoprenoid compounds including cholesterol, squalene, the terpenes, and natural rubber. While working on the mechanism of fatty acid synthesis from malonylcoenzyme A, he isolated fatty acid synthetase, a multi-enzyme complex concerned with the key reactions of this process. He further found that biotin, an essential co-factor of this enzyme complex, binds carbon dioxide to form activated CO₂, which he identified as 1-N-carboxybiotin. Lynen's team worked also on the biosynthesis of the amino acid cystine, and the formation of acetoacetic acid in liver. (W. W. Z.)

LYNN, a city of Essex County, Mass., U.S., on the northern shore of Massachusetts Bay, 11 mi. NE of Boston. Established in 1629 as Saugus, it was organized as a village in 1631, and in 1637 was renamed after Lynn Regis in England. It was incorporated as a city in 1850. The first smelting works in America was built there in 1643, several tanneries were established and shoe-making, beginning in 1635, had by the middle of the 18th century brought prominence and prosperity to the town. A century later, the introduction of the sewing machine and steam power led to the development of the factory system, an influx of immigrant workmen, and Lynn's emergence as the foremost shoe centre in the country.

During the 1930s shoe manufacture declined in importance and by the second half of the 20th century electrical machinery and transportation equipment had become the principal manufactures. Pop. (1960) 94,478. For comparative population figures *see* table in MASSACHUSETTS. (L. G. BA.)

LYNTON and LYNMOUTH, seaside villages in the Lynton urban district (pop. [1961] 1,918) of Devon, Eng., lie on the Bristol channel about 17 mi. N.E. of Barnstaple. Lynmouth, at the mouth of the East and West Lyn rivers, and Lynton, on the cliff top 500 ft. above, are linked by a steep road, and a cliff railway 900 ft. long, which was cut through the woods and opened in 1890. In August 1952 the East and West Lyn rivers, swollen by a cloudburst of tropical intensity, ravaged Lynmouth, killing 31 persons. Lynmouth has a small harbour with a Rhenish tower, reconstructed since the flood havoc; and a public hall built in memory of the flood victims. Lynton has quaint old streets and houses but with a modern section, and a fine half-timbered town hall. Both are summer resorts situated in the Exmoor National Park. *See* EXMOOR.

LYNX, the generic and common name of several medium-sized cats having short tails, long legs, large paws, tufted ears and broad, short heads. Each upper jaw has only two premolar teeth whereas typical cats have three. There are two distinct types: the northern lynx (*L. lynx* of Eurasia; *L. canadensis* of North America) and the bay lynx or bobcat (*L. rufus* of North America). The northern lynx is a forest dwelling cat with unusually large paws and hairy soles, a somewhat mottled tawny to cream coat and a black-tipped tail. In winter the fur is dense and soft, the hairs up to 4 in. long, and is sought for trimming garments. The Eurasian species occurs southward to central Europe, Turkistan and Tibet. It is the largest wild felid of Europe. The Canadian lynx formerly extended southward into the northern tier of the United States and farther in the Rockies, where it is now rare. It feeds on small mammals, even young deer, subsisting mainly on the snowshoe rabbit. Breeding takes place in March, and the one

WILLIAM W. BACON—RAPHO GUILLEMETTE

CANADIAN LYNX (LYNX CANADENSIS)

to four young are born two months later. They are nocturnal and extremely shy.

The bobcat occurs from southern Canada to the Isthmus of Tehuantepec. It differs from the northern lynx in having shorter ear tufts and being generally smaller bodied. The colour and thickness of the coat are variable according to the habitat. The pelt is of less commercial value than that of the northern lynx, being somewhat brittle. The bobcat is equally at home in forests or deserts and, unlike its northern relative, is much less inclined to climb trees. (K. R. KN.)

LYON, MARY (MASON) (1797–1849), U.S. educator and pioneer in the field of higher education for women, was born on Feb. 28, 1797, on a farm near Buckland, Mass. She began to teach when she was 17, and in 1817, with earnings from spinning and weaving, she went to Sanderson academy, Ashfield, where she was distinguished by her extraordinary mental quickness. She supported herself there and at the other academies she attended by teaching, her desire to acquire and impart learning seeming insatiable. Her success as a teacher and administrator and the demand for the young women she trained led to her plan for "a permanent institution consecrated to the training of young women for usefulness . . . designed to furnish every advantage which the state of education in this country will allow . . . to put within reach of students of moderate means such opportunities that none can find better." She was aided in this effort by Edward Hitchcock, the geologist, with whom she had studied. This assistance, reinforced by her own enthusiasm and practical common sense, secured for her plan the necessary financial support. In 1835 a site was selected near the village of South Hadley. The school was incorporated in 1836 as Mount Holyoke Female seminary; and on Nov. 8, 1837, it opened with Mary Lyon as principal and Eunice Caldwell, afterward well known as Mrs. J. P. Cowles of Ipswich academy, as assistant. Miss Lyon died at Holyoke on March 5, 1849, having served nearly 12 years as principal of the seminary. Her work at Mount Holyoke represented an important step in the higher education of women.

BIBLIOGRAPHY.—Edward Hitchcock, *Life and Labors of Mary Lyon* (1851); Beth B. Gilchrist, *Life of Mary Lyon* (1910); E. C. Adams and W. D. Foster, *Heroines of Modern Progress* (1913); Gamaliel Bradford, *Portraits of American Women* (1919).

LYON, NATHANIEL (1818–1861), U.S. soldier during the early phase of the American Civil War, was born in Ashford, Conn., July 14, 1818. After graduating from the U.S. Military academy in 1841 he was assigned to fighting the Seminole Indians in Florida. He served in the Mexican War, and after spending several years in California was sent to "Bleeding Kansas" in 1854. He joined the Republican party and wrote several articles for the *Manhattan* (Kan.) *Express* attacking Buchanan and Douglas and supporting Abraham Lincoln. Lyon was transferred to St. Louis on Feb. 6, 1861. He immediately got in touch with Francis P. Blair, Jr., and other leading Unionists in that city. After Blair's intercession, Lyon was placed in command in eastern Missouri. He seized the Confederate base at Camp Jackson on May 10, 1861, and began the arming of Union volunteers. He took part in a final attempt at compromise, meeting with Blair, Maj. Gen. Sterling Price and the secessionist governor, Claiborne F. Jackson, at the Planters hotel. The attempt failed and Lyon commented upon its conclusion, "This means war." On June 13, Lyon moved up the Missouri river with 2,000 regulars, capturing the Missouri capital at Jefferson City, June 15, and Boonville, June 17. He followed the Confederate forces into southwestern Missouri, finally bringing them into battle at Wilson's creek, Aug. 10. Although Lyon himself was killed and his forces defeated, his prompt actions in eastern and central Missouri were a large factor in saving that state for the Union. See also *MISSOURI: History*. (J. M. Wo.)

LYONIA, a genus of evergreen or deciduous shrubs of North America and Asia belonging to the heath family (Ericaceae). They have alternate, short-petioled leaves and white or pinkish flowers in dense axillary or terminal clusters. Three species common in the eastern United States are grown as ornamentals: the swamp or privet andromeda, male berry or he-huckleberry (*L. ligustrina*), a deciduous shrub to 12 ft., bearing oval leathery leaves, occurring

from Maine to Florida; the fetterbush (*L. lucida*), an evergreen to 6 ft. high, with lustrous leaves, found from Virginia to Florida, and the staggerbush or wicopy (*L. mariana*), a deciduous shrub to 6 ft., found from Rhode Island to Florida. (J. M. Bl.)

LYONNAIS, a French province or *gouvernement* of the *ancien régime*, bounded on the north by Burgundy, on the east by Dombes, Bresse and Dauphiné, on the south by Languedoc and on the west by Auvergne and Bourbonnais. It was formed in the 16th century when Beaujolais (see *BEAUJEU*) and Forez (*q.v.*) were merged with the older Lyonnais. This older Lyonnais comprised the territory dependent on Lyons west of the Saône and Rhône rivers as far as the Monts du Lyonnais; east of the Rhône in the immediate vicinity of Lyons; and east of the Saône north of Lyons, where the country round Vimy (Neufville-sur-Saône) had the right to vote its own taxes and so was called the Franc-Lyonnais. Converted into the *département* of Rhône-et-Loire in 1790, it was divided into those of Rhône and Loire in 1793.

LYONNESSE (LYONESSE, LENNOYS or LEONAI), a mythical lost land supposed to have once connected Cornwall, Eng., with the Scilly Isles. That such a land could really have existed within historical memory is of course impossible. The name Lyonesse first appears in Sir Thomas Malory's *Morte Darthur*, where it is the native land of the hero Tristan (*q.v.*). In the 12th-century French *Tristan* poem by Béroul the hero is called Tristan de Loenois, a name already used by Wace to translate Geoffrey of Monmouth's Lodonesia, i.e., Lothian in Scotland. In the 13th-century French prose *Tristan*, the name sometimes appears as Leonois, probably by identification with the region round St. Pol-de-Léon in Brittany, and this form is the source of Malory's Lyonesse. Following the prose *Tristan*, Malory assumes that Cornwall and Lyonesse are contiguous kingdoms, both in Great Britain.

The earliest reference to a drowned land, containing 140 parishes and extending from St. Michael's Mount to the Scilly Isles, occurs in the 15th-century Latin prose work, the *Itinerary of William of Worcester*. A tradition concerning a submerged forest near Avranches was known to the monks of Mont-Saint-Michel in Normandy in the 13th century. As the monastic traditions of Mont-Saint-Michel were freely borrowed by the daughter house of St. Michael's Mount, the account in the *Itinerary* may reflect the French inundation story as modified by the Cornish monks. William Camden in his *Britannia* (1586) refers to the drowned land as Lyonesse, but it was really the Cornish antiquary, Richard Carew of East Antony (1555–1620), who was responsible for giving the land this name, which he drew from Malory's account of Tristan's kingdom. Carew's *Survey of Cornwall* was first printed in 1602, but Camden is known to have had access to the work while it was still in manuscript. This learned fabrication has since been widely and uncritically accepted as genuine Cornish folklore.

See A. D. H. Bivar, "Lyonesse: The Evolution of a Fable," *Modern Philology* (Feb. 1953).

LYONNET, PIERRE (1707–1789), Dutch naturalist and insect anatomist, was born at Maastricht, Holland, on July 22, 1707, and after being trained as a lawyer, devoted most of his time to engraving objects of natural history. He made the drawings for Lesser's *Theology of Insects* (1742) and for A. Trembley's treatise on hydra, *Mémoires pour servir à l'histoire d'un genre de Polyptes d'eau douce* (1744). Finally he produced a monograph on insect anatomy published in 1760 under the title *Traité anatomique de la Chenille qui ronge le bois de Saule*. He engraved his own figures on copper, and his drawings are remarkable not only for their skill but also for the extraordinary amount of detail shown. He distinguished no fewer than 4,041 separate muscles in the caterpillar of the goat moth and showed the nerves and tracheae in a manner never previously attempted. The extraordinary character of these drawings caused a sensation, and Lyonnet was accused of embellishing reality with fanciful detail. In a second edition, published in 1762, Lyonnet answered his critics by giving drawings of his instruments and a description of his methods. His monograph remains one of the most beautiful accounts of insect anatomy ever published. He died at The Hague on Oct. 10, 1789. Notes and drawings intended for a *Recueil historique*, illustrated by 54 plates dealing with various insects, were published

in the *Mémoires du Musée d'Histoire naturelle* (1829-32).

(Ed. He.)

LYONS, SIR JOSEPH (1848-1917), British businessman, was born in London on Sept. 29, 1848, and educated at a Jewish school. In early life he studied painting and exhibited at the Royal institute, but by 1886 he had turned to business enterprises, in conjunction with the brothers Isidore and Montague Gluckstein. This led to the foundation of the catering firm of J. Lyons and Co., Ltd., of which he became chairman. He began by catering at public exhibitions, and next opened teashops in London, the first in 1894. Twenty years later these numbered more than 200 and provided inexpensive food for the large numbers of clerical workers and junior members of professions. Later he opened several restaurants of a more ambitious nature, as well as hotels, on the no-tipping principle. He was knighted in 1911, and died in London on June 22, 1917.

LYONS, RICHARD BICKERTON PEMELL LYONS, VISCOUNT (1817-1887), British ambassador at Paris for 20 years, was born at Lymington, Hampshire, on April 26, 1817, the elder son of Edmund, Baron Lyons, who commanded the British fleet in the Crimean War. He was educated at Winchester and Christ Church, Oxford, and entered the diplomatic service (1839) as attaché to his father, who was then British minister at Athens. He served in turn at Dresden, Rome and Florence, and was at Washington, D.C., as British minister from 1859 to 1865. During the American Civil War his tact helped to prevent Anglo-American hostilities arising from the arrest of Confederate envoys on the British mail steamer "Trent." After a brief period at Constantinople he became ambassador at Paris in 1867. He continued in this post until 1887.

An exceptionally able and judicious public servant, Lyons had the rare gift of making no enemies, and enjoyed the full confidence of successive governments in London and Paris alike, even when French opinion was as intensely inflamed against Great Britain as it was during the early days of the British occupation of Egypt. He refused an offer from Lord Salisbury of the foreign secretaryship in 1886, as his health was giving way. He had succeeded his father in the barony in 1858, and was created Viscount Lyons of Christchurch on Nov. 24, 1881. After his retirement from office in Oct. 1887, he was to have received an earldom, but he died, in London, on Dec. 5, 1887, before the honour was conferred. As he had never married, and his brother had been killed in the Crimea, the viscountcy became extinct.

See Lord Newton, *Lord Lyons*, 2 vol. (1913). (M. R. D. F.)

LYONS (LYON), the chief town of the *département* of the Rhône, France, the seat of an archbishop and the headquarters of a military region, lies 472 km. (293 mi.) S.E. of Paris and 328 km. (204 mi.) N. of Marseilles by road. Sheltered by the foothills of the Massif Central to the west and by the southern heights of the Jura mountains to the northeast, Lyons is situated at the confluence of the Rhône and Saône, on the narrow peninsula between the rivers and on their opposite banks. Pop. (1962) 524,834. The contrasting heights of the hills on which the city is built, varying from 450 to over 1,000 ft., give Lyons an unusually picturesque appearance. The summit of Fourvière on the right bank of the Saône is reached by funicular railway and offers the best view of the whole town—of its rivers, its bridges and its roofs of pinkish tile. At Fourvière (Forum Vetus) excavations begun in 1933 revealed a theatre of the Greco-Roman type and an odeum (for musical contests) of the 1st and 2nd centuries A.D. The hill, covered with convents and hospitals, is dominated by the church of Notre Dame de Fourvière. This modern basilica (1894), with its elaborate marble and mosaic decoration, is a place of pilgrimage. Close by, a metal tower 262.5 ft. high, built in 1893, supports television aerials. Bordering the right bank of the Saône, "Old Lyons," grouped around the cathedral, is an extraordinary accumulation of medieval and Renaissance buildings having great windows and inner courtyards with galleries and turrets. The cathedral, dedicated to St. John the Baptist, was built between the 12th and 15th centuries. Its apse is a masterpiece of Lyonnais Romanesque; the Gothic nave dates from the 13th and 14th centuries as does the fine stained glass in the choir; there is some remarkable carving

on the west front. Farther north, along the same bank of the Saône, is the church of St. Paul with its octagonal lantern tower dating from the 12th century. The exchange (by J. G. Soufflot), now a Protestant church, and the archbishop's palace (since 1911 housing the municipal library) are both 18th-century buildings. The ponderous law courts are of the following century. On the peninsula, among buildings of diverse styles, traces of the old medieval city can be seen here and there. The Romanesque porch of St. Pierre-des-Terreux and the oldest church in Lyons, St. Martin d'Ainay (1107), are examples. The straight roads running from north to south on the peninsula, Rue Victor Hugo, Rue de la République and Rue de l'Hôtel de Ville (renamed Rue Président Herriot in 1958), which carry much of the business traffic, were constructed in the latter half of the 19th century. To the north is the hill of Croix Rousse with the tall houses of the silk weavers, and at its summit the baroque church of St. Bruno-des-Chartreux. The 17th-century group of buildings around the Place des Terreaux is particularly beautiful, especially the *hôtel de ville*, one of the masterpieces of French civic architecture, begun in 1646 by the Lyonnais Simon Maupin, and the palace of St. Pierre, formerly a Benedictine abbey, built between 1659 and 1685 in the Italian baroque style. In front of the *hôtel de ville* is a fountain designed by the 19th-century sculptor F. A. Bartholdi. The churches of St. Nizier and St. Bonaventure are Gothic buildings of little interest. The opera house, the Bourse and the Théâtre des Célestins, built in the 19th century, are also in this district. Facing the Rhône between the Wilson bridge and the La Guillotière bridge is the 17th-century Hôtel Dieu for which Soufflot designed the façade in the following century. The Bellecour quarter is characterized by elegant 18th-century hotels and buildings. From the Place de Bellecour, with its equestrian statue of Louis XIV, the Rue Victor Hugo leads via the Place Carnot to the Perrache quarter with its docks, hostels and warehouses. This district, at the southern tip of the peninsula, was named after the most famous of the 18th-century engineers who worked to extend the confluence farther south.

On the left bank of the Rhône are the new districts of Lyons with busy streets and broad shady embankments. There are the university and the prefecture, and also the wealthy residential quarter built around the large park of La Tête d'Or, containing a lake, a zoological collection and fine botanical gardens. Farther east are industrial suburbs, with the medical university, the Édouard Herriot hospital and the new municipal stadium. Around the town, especially to the northwest and east, are many populous communes, the most important being Villeurbanne. The industrial outskirts are constantly expanding into the plain of Dauphiné. The university (1896) is the most important in France, after Paris; it has a veterinary school founded by C. Bourgelat in 1762 (the oldest in the world). Mention should also be made of the Central School of Lyons (1857), the dental school, the Institute of Industrial Chemistry (1883), the Military Medical school and the National Institute of Applied Science (1957). In addition to the university library, there is the municipal library possessing a fine collection of books, manuscripts, incunabula, prints and engravings. The most important of the city's 21 museums are: the museum of fine arts in the Palais St. Pierre, where Perugino's altarpiece, works of the 19th-century Lyonnais school and a fine picture of the Tahiti period by Gauguin are among the chief treasures; the museum of textiles and the museum of decorative arts in the 18th-century houses of the Rue de la Charité, where the history of the weaving industry is illustrated; the historical museum in the old Hôtel de Gadagne, which contains an international collection of marionettes; the Guimet museum (natural history); and the museum of printing in the former medieval town hall.

Transport and Communications.—Situated on the banks of two rivers and guarded by the surrounding hills, Lyons naturally commands a number of routes: to Paris by the valley of the Saône, across Burgundy to the Rhine, to Switzerland and Italy by the upper Rhône, westward through the valley of St. Étienne and to the Mediterranean by the corridor of the lower Rhône. Since the beginning of its history, Lyons has owed much of its prosperity to river traffic. In spite of the junction of road and rail routes,

three harbours are in use, and shipping in these doubled between 1926 and 1955. The Saône is connected by canal with the basins of the Loire, Seine and Rhône. Roads from east to west across the peninsula are connected by no fewer than 27 bridges. The problem of traffic in this direction was made easier by the tunnel of the Croix Rousse, the longest road tunnel in France (5,748 ft.), connecting the Delattre de Tassigny bridge on the Rhône to the Clemenceau bridge on the Saône.

The first railway in France to use a steam engine was built between St. Étienne and Lyons (1826-33), and the great Paris-Lyons-Mediterranean line was built in 1850. Since the electrification of the line, some of the fastest trains in the world run between Paris and Lyons, which is also a main-line station for Switzerland and Italy. Other lines connect Lyons with Brittany, Alsace-Lorraine and Languedoc.

Air services operate from the airport at Bron, one of the first in France. It was destroyed in World War II but was later reconstructed and steadily improved thereafter.

Industries.—Since the 16th century Lyons has been the centre of a silk industry originally derived from Italy. The first Lyons silk weavers were Piedmontese workers that the town council secured by privilege in 1536. Under the patronage of succeeding kings the silk trade developed enormously and grew into the *Grande Fabrique*, unrivaled in the 18th century. It remained the chief source of the city's prosperity until the end of the 19th century. The designs were made by local artists such as Philippe de la Salle, and the work was done by the local weavers in the town and surrounding countryside. The invention of the weaving loom by J. M. Jacquard (1752-1834) gave a new impetus to the industry. In the mid-19th century more and more silk-weaving factories were established in the southeast; nevertheless, Lyons remained the controlling centre for the silk trade of the world. The manufacture of chemicals, dyes and synthetic fibres has developed largely to meet the industry's requirements, and Lyons' chemical industries are second in importance in France only to those of the Paris region. Allied industries produce mineral and vegetable colouring matters, gelatin, glue, fertilizers and pharmaceutical and plastic products. The metal industry, including mechanical construction and motor and electrical engineering, has surpassed textiles in importance, however, and is the largest employer in the Rhône département. The electric cables of Lyons are world famous and there are sheet-iron works, foundries and wire mills.

History.—The earliest Gallic people who occupied the territory at the river confluence were Segusians. In Oct. 43 B.C. Lucius Munatius Plancus, a former lieutenant of Caesar's, founded a colony, Lugdunum (*q.v.*), on the hill above the confluence. The importance of the site as a node of communications had turned Lyons into a political centre by the 2nd century. Five great roads radiated from it, toward Aquitaine, the Atlantic, the Rhine, Italy and the Mediterranean; three towns surrounded it, the Roman Fourvière, the Gallic Condate on the slopes of the Croix Rousse and the settlement of boatmen and merchants on the Isle of Ainay. Augustus and Caligula lived at Lugdunum and the emperors Claudius, who gave Roman citizenship to the Lyonese, and Caracalla were born there. In the 2nd century Christianity reached Lyons. In 177 its Christian community was persecuted by Marcus Aurelius, and in 197 the city was burned and ravaged by Lucius Septimius Severus, so that by the 5th century it was no more than the chief town of a province of Gaul.

The barbarian invasions preceded the coming of the peace-loving Burgundians who made Lyons their capital in 470. Under the Franks, churches and monasteries were built by the bishops. In 1032 Lyons was incorporated into the Holy Roman empire under Conrad II, having previously been the chief town of the kingdom of Provence and then of part of Burgundy. The real power lay with the archbishops and under their authority two ecumenical councils were held there, one in 1245 when Innocent IV deposed the emperor Frederick II, and one in 1274 when Gregory X proclaimed the reunion of the Greek and Latin churches (*see* COUNCIL). In 1305 Clement V, the first pope of Avignon, and in 1316 John XXII, both Frenchmen, were crowned popes at Lyons. The Lyonesse, having revolted against their prince-archbishop, appealed

to Philip the Fair who, in 1312, annexed the town to the French crown. From then on it was administered by elected consuls.

Lyons remained faithful to the king during the Hundred Years' War. Louis XI granted it the privilege of four annual fairs in 1463 and in the 16th century it entered into its most prosperous period. During the wars with Italy, Lyons was the seat of the court and the government; the wealth of its merchants, bankers and printers and the work of its writers and poets, such as Louise Labé and Maurice Scève (*q.v.*), made it, in fact, the political and literary capital of France and the largest commercial and financial centre. This prosperity was lost during the wars of religion, the Protestant occupation of 1562 and the Lyonesse massacres of St. Bartholomew of 1572. Held in check by the absolute monarchy, Lyons once again became no more than the chief town of the united province of Lyons, Beaujolais and Forez.

At the time of the Revolution the town was suffering from an economic crisis. As a supporter of moderate and royalist factions, it was besieged by the army under Gen. F. C. Kellermann from Aug. 8 to Oct. 9, 1793, and was forced to surrender to the republicans. It was condemned to partial destruction and to the loss of its name for that of "*commune-affranchie*," and 2,000 of its citizens were guillotined or shot. Under the first empire its prosperity returned. The wretched condition of the working classes provoked risings in 1831, 1834 and 1849.

The 20th century saw the steady urban and industrial expansion of the city. An annual international sample fair was first staged in 1916 by Édouard Herriot, the city's most illustrious mayor (from 1905 to 1957), who became prime minister and president of the national assembly. Under German occupation (1940-44) in World War II, Lyons was the headquarters of the French resistance movement and, in its region alone, 5,000 people were executed by the Gestapo.

See also references under "Lyons" in the Index. (Hv. J.)

LYOT, BERNARD FERDINAND (1897-1952), French astronomer, inventor of the solar coronagraph, which makes possible the observation of the solar corona when the sun is not in eclipse, was born in Paris on Feb. 27, 1897. He started his astronomical researches in the 1920s with measurement of polarization of light from the moon and planets, using a new sensitive polarimeter constructed by himself. He showed that the moon's surface behaves as though covered with a layer of dust, that Mercury can have at most a very tenuous atmosphere, that polarization from Mars is sometimes affected by haze or dust and that there are irregularities over the Martian south polar cap, attributable to the formation of clouds. Venus was found to be covered by a continuous cloud layer composed of droplets of diameter about 2μ and of refractive index near that of water.

In 1931 Lyot successfully observed the solar corona in broad daylight, an achievement at that time generally regarded as impossible, using a new form of telescope, much of which he carried on skis to the summit of the Pic du Midi in the Pyrenees. Two years later he perfected a polarizing filter, of the type now known by his name, permitting single exposure monochromatic photography of the whole sun in a band width about one Angström. During the 1930s he measured day-to-day changes in the solar corona, particularly in the light of the 5303 and 6374 Å lines, and also added much to our knowledge of the coronal spectrum (*see* CORONA). His pioneer motion-picture films, showing movement in solar prominences in the light of the red hydrogen H α line, were unsurpassed in quality for many years and added new and unexpected knowledge in this field. At the Pic du Midi he also made some of the finest planetary photographs obtained until that time. He showed that if the moon has an atmosphere the density cannot exceed one hundred millionth of that of the earth's atmosphere.

Lyot relied greatly on apparatus with virtually flawless optical surfaces and therefore invented new and sensitive methods of examining very small defects of glass structure or of surface polish. He designed a large new spectrograph for examining the light of the night sky. One of his last achievements was the construction of electronic apparatus allowing observations of the solar corona from places near sea level.

Lyot's work, consistently of the finest quality, was character-

ized by great originality and elegance. He was awarded the gold medal of the Royal Astronomical society in 1939 and the Bruce medal of the Astronomical Society of the Pacific in 1946. He died on a train between Cairo and Helwan, Egy., April 2, 1952.

LYRA (the Harp) is a constellation seen in the northern hemisphere. It contains Vega (α Lyrae), one of the brightest stars in the sky, whose name is a remnant of an Arabic phrase meaning "falling eagle." The double star β Lyrae is an eclipsing variable with a period of 12.92 days; the system presents some abnormal features, perhaps owing to the very low densities of the two components. The star ϵ Lyrae is a double double; a binocular or even the unaided eye shows two stars, and a small telescope resolves each of these into two components. The Ring nebula in Lyra (Messier 57) is the brightest example of this class of nebula.

LYRE, a type of stringed musical instrument that was widespread in the ancient Mediterranean world and near east and is still used in Arabia and parts of Africa. It is characterized by a sound box from which project two arms joined by a yoke; the shape of the sound box varies between instruments. The strings run from the sound box over a bridge to the yoke, where they are tuned by means of twisted thongs or pegs; they are plucked with the fingers or with a plectrum.

The lyre is known in Mesopotamia from the Sumerian period onward; it was introduced into Egypt not later than the 19th century B.C. Size, construction and the number of strings vary greatly. Splendid specimens have survived from Ur (25th century B.C.). These are about 3 ft. 6 in. high. Giant lyres that stand on the ground and are played by a seated player are seen on Mesopotamian reliefs from the 3rd millennium and later in Egypt (Amarna period). Smaller, portable instruments (Babylonia, Egypt, Syria, Assyria) were held horizontally or lying in the arms; their construction was often asymmetrical. The Hebrew *kinnor* was probably a lyre.

In Greek lands there is evidence of lyre-type instruments with seven or more strings—probably related to Asiatic types—during the Minoan-Mycenaean civilizations. Vase paintings of the 8th century B.C. show a simple variety with from three to five strings that can be identified with the phorminx of Homer. From the 7th century B.C., probably under renewed Asiatic influence, the main classical varieties became established, with seven strings at first.

The lyra had a sound box made of tortoise shell (later wood) and slender curved arms. This was the instrument of the school-boy and the amateur; players are generally shown seated with the lyre resting on the left hip. The barbiton, a subtype of the lyra, had longer strings and lower pitch.

The instrument of the professional was the cithara, which was

larger and more solidly built, the hollow arms forming a substantial prolongation of the sound box. The citharoedus (singer to the cithara) stood on a small platform, his decorative instrument resting against his body and supported in position by a band attached to his left wrist.

There were two main varieties of cithara: the first, an elaborately constructed instrument with a flat base; the second, a much simpler instrument with a rounded base that was favoured by less pretentious players.

With both the lyra and the cithara, the left hand was spread over the strings, while the right hand held a plectrum. The precise function of the two hands is still uncertain. Though strings numbering up to 12 were added to the cithara by virtuosos of the late 5th century B.C., the number 7 was canonical in the classical period. It is debated whether each string provided one note only or whether it was possible to obtain notes of higher pitch by stopping.

During the Roman period new varieties of cithara emerged. The lyre of medieval Europe (*rote*) tended to depart from the type by the addition of a finger board and the use of a bow; e.g., the Welsh *cruith* (q.v.), which was still played in the early 19th century. A similar instrument, the *kantele*, is still played in Finland and Estonia.

In Africa, e.g., Sudan, Ethiopia, Uganda, the lyre survives in a form not unlike that of the ancient world and is used, as in Homer's day, to provide an accompaniment for the professional singer.

(R. P. W.-I.)

LYREBIRD, the name for Australian birds of the genus *Menura*, which resemble in some respects the scrubbirds (q.v.). Somewhat smaller than a pheasant, the lyrebird is the largest of the perching birds. The common superb lyrebird (*M. superba*), of the woodlands of eastern Australia, is the best known. The male is remarkable not only for his tail feathers, which when displayed bring to mind an ancient lyre, but also for his vocalizing, which is sometimes musical, sometimes uncannily imitative of a wide range of sounds. The female has a fowl-like tail and apparently lacks the vocal ability of the male. Both sexes have brownish body feathers. The cock's tail feathers number 16; the outermost on either side, broad, curved and more than two feet long, are whitish with prominent brown marks; the central plumes are delicate and lacy. Contrary to popular belief, the tail displayed in a vertical attitude is rarely seen; it is a fleeting position passed through as the tail is fanned forward and over the body, concealing the bird under a lacy canopy.

Lyrebirds are very shy, inhabiting the thickest underbrush. The cock builds small mounds within his territory on which he displays and sings. The food consists of insects and other small invertebrates. A domed nest, on or near the ground, is closely woven of roots and fibres and lined with feathers. A single purplish-gray egg, darkly blotched, is incubated by the hen for about six weeks; the chick, naked at hatching, quickly becomes covered with dark down.

Another species, Albert's lyrebird (*M. alberti*), named for Queen Victoria's consort, is more rust coloured and has less prominent tail feathers than the superb lyrebird. (Ht. Fn.)

LYSANDER (d. 395 B.C.), son of Aristocritus, won the final victory for Sparta in the Peloponnesian War and wielded great power at its close.

Nothing is known of his early career (stories of his humble birth must be discounted). His first year as admiral (407) was spent mainly in negotiation with the Persian viceroy, Cyrus the Younger, in preparation and in political activity, the only recorded action being his victory at Notium (early 406). His partisans made great difficulties for his successor Callicratidas, and when the latter was killed at Arginusae in August 406 they joined with Cyrus in demanding Lysander's reappointment. Spartan law forbade a second term, so he went out nominally as second-in-command early in 405. His victory at Aegospotami in September closed the corn route

INSTRUCTOR AND PUPIL PLAYING THE LYRE BENEATH HANGING CITHARA AS
DEPICTED IN SCHOOL SCENE ON ATHENIAN VASE, 5TH CENTURY B.C.

through the Hellespont, starving Athens into surrender (April 404). Some time after the formal surrender he returned to Athens and helped to set up the oligarchy of the Thirty Tyrants, after which he returned in triumph to Sparta.

Lysander had used his period of power to support narrow oligarchies everywhere: many cities were ruled by a board of ten (decarchy) of his partisans, and some had garrisons under a Spartan commander (harmost). He aimed at a Spartan empire, wider than the Athenian and under strict control, but the attempt failed. The record for 403 is confused and partly fictional, but it is certain that Lysander was sent to support the Thirty at Athens against Thrasybulus' democratic revolt, and was nearly successful when King Pausanias secured the support of a majority of the ephors for his intervention. The settlement, which allowed the restoration of democracy at Athens, was a defeat for Lysander. The decarchies were probably abolished, though some maintain they survived till 397 and deny that Lysander suffered a political eclipse.

On the death of Agis II, probably in 400, he helped Agesilaus II to the throne, and he headed the 30 Spartan officers who accompanied Agesilaus to Asia in 396. At first he engrossed all the expedition's business, but Agesilaus undermined his authority. In 395 he returned home. In the summer war broke out with Thebes, and Lysander led an army of Sparta's northern allies into Boeotia, won over Orchomenus and marched to Haliartus to meet Pausanias and the Spartan army. Lysander arrived first, attacked the town alone and was killed. He was buried at Panopeus in Phocis, and Pausanias after a second trial went into exile.

A very able soldier and politician, Lysander was wholly ruthless in pursuit of his own and Sparta's ambitions and made many enemies. He was credited with plans to alter the constitution to an elective monarchy, and though this theme has been embroidered it may have a basis of truth.

LYSENKO, TROFIM DENISOVICH (1898—), a Soviet agronomist, graduate of the Kiev Agricultural Institute, who rejected orthodox genetics in favour of "Michurinism" (named for the Russian horticulturist I. V. Michurin). Michurinism, widely regarded as a form of Lamarckism (*q.v.*), more properly should be compared with the school of Luther Burbank (*q.v.*). It was begun by an uneducated plant breeder fashioning explanations of his hybrid fruit creations. After Michurin's death in 1935, Lysenko led the movement and transformed it into an assault on orthodox genetics.

It is historically true that Lysenko's Michurinism was buttressed by the Stalinist version of Marxism. The Soviet chiefs began to support Lysenko during the agricultural crisis of the 1930s. On the basis of rather crude and unsubstantiated experiments, Lysenko promised greater, more rapid, and less costly increases in crop yields than other biologists believed possible. Under Stalin, Lysenko became director of the Institute of Genetics of the Academy of Sciences of the U.S.S.R. and president of the then powerful V. I. Lenin All-Union Academy of Agricultural Sciences. By 1948, when education and research in standard genetics were virtually outlawed, some geneticists had suffered secret arrest and death of undisclosed causes. After Stalin's death, in 1953, some of Lysenko's agricultural programs were abandoned but not entirely discredited; orthodox geneticists won limited freedom of teaching, research, and publication; and some condemned biologists were posthumously reinstated.

It is misleading to regard the inheritance of acquired characters as the primary issue in Lysenko's clash with orthodox geneticists, who, since the 1920s, have been making their own studies, precise and controlled, of environmentally induced changes in heredity. Lysenko rejects the basic concepts and methods of these experiments. He disregards the statistically justified distinction between genotype (genetic endowment) and phenotype (physical appearance). He insists that all parts of the organism are equally involved in heredity (which recalls Darwin's early doctrine of pangenesis), that chromosomes play no special role, that genes do not exist. His own "theories" are too vague or too question-begging to be taken seriously by most geneticists. His central principle,

"the unity of the organism with its environment," can mean anything he chooses it to mean. His "directed changes in heredity" neglects the statistical rigour and the initial purity of stock required by standard genetical concepts (these he rejects in advance). His school has also been charged with falsifying data.

Lysenko's doctrines and claims have varied with the amount of power he has held. Between 1948 and 1953, when he was the total autocrat of Soviet biology, he claimed that wheat plants raised in the appropriate environment produce seeds of rye, which is equivalent to saying that dogs living in the wild give birth to foxes. His fundamental, continuing argument is that theoretical biology must be fused with Soviet agricultural practice. After Stalin's death, this principle caused Lysenko some embarrassment, for efforts to improve Soviet agriculture brought the abandonment of measures to which his name and fame were tied. For example, the "grassland" system of crop rotation was abandoned in favour of intensive cultivation with heavy use of mineral fertilizers, and a hybrid corn program based on the American example has been energetically pursued (Lysenko put a halt to such a program in the mid-1930s, for he was opposed to the inbreeding with which it must begin). During N. S. Khrushchev's premiership, opposition to Lysenko's programs was tolerated, and Lysenko lost titular control of the Lenin Agricultural Academy. After Khrushchev's political demise, in the autumn of 1964, Lysenko's doctrines were discredited and intensive efforts made toward the reestablishment of orthodox genetics in the U.S.S.R. Deposed as director of the Institute of Genetics early in 1965, Lysenko seemed to be at the end of his mutable career. See also **GENETICS: Soviet Genetics**.

LYSIAS (c. 445–after 380), a Greek professional speech writer at Athens, noted for the charm and purity of his prose. His father, Cephalus, was a native of Syracuse who was said to have settled in Athens at the invitation of Pericles. Plato, who seems to have known the family well, gives a charming picture of Cephalus and his sons at the beginning of the *Republic*. After his father's death Lysias, then aged 15, went with his brother Polemarchus to Thurium in southern Italy where, according to an ancient source, he studied rhetoric under the Syracusan rhetorician Tisias. In 412 the brothers returned to Athens, where they settled as *isoteleis* (a specially favoured class of aliens). They derived a substantial income from a shield factory in Piraeus. A statement ascribed to Aristotle that Lysias taught rhetoric may refer to this period.

The fortunes of the brothers changed after the fall of Athens in 404 when the Thirty Tyrants attacked the persons and property of resident aliens. Polemarchus was killed. Lysias was arrested, but escaped to Megara, and from there he helped the cause of the exiled democrats. On the restoration of democracy in 403 a decree was passed conferring citizenship on Lysias, but it was later declared invalid owing to some technical irregularity. He spent the rest of his life at Athens as a professional writer of speeches for litigants. The only occasion on which he appeared personally in the courts was in 403 when he prosecuted Eratosthenes, one of the Thirty. Dionysius of Halicarnassus has preserved the fragment of a speech supposed to have been delivered by Lysias at the Olympic festival of 388. His latest extant speech is dated c. 380.

Of the large number of speeches ascribed to Lysias by antiquity 34 have survived. Some of these are incomplete and some are probably spurious. Small fragments of others have been preserved and their number has been increased by modern papyrological discoveries. A rhetorical trifle in Plato's *Phaedrus* purports to be the work of Lysias. It pleads the case of a suitor who is not in love with a boy. Some think it was in fact written by Lysias, but it is more commonly regarded as a pastiche by Plato.

The most interesting of the nonlegal speeches is the *Olympios* (xxxiii), which Lysias is said to have delivered at Olympia in 388. In it he appeals to the Greeks to unite against the tyranny of Dionysius the Elder of Syracuse. The ornate style, which is char-

acteristic of epideictic, or ceremonial, oratory, is in contrast with the unpretentious simplicity of Lysias' legal speeches. The *Epitaphios* (ii), written in honour of Athenians killed during the Corinthian War (395–386), is probably spurious. There is a substantial fragment of a political speech (xxxiv), ostensibly delivered in the ecclesia, which is directed against a proposal to limit the ancient democratic constitution after the fall of the Thirty in 403.

The other extant speeches are all legal and on these Lysias' fame rests. Most of them were written for public cases. The longest and most famous is that "Against Eratosthenes" (xii; *Kata Eratosthenous*) in which Lysias denounces one of the Thirty, whom he held responsible for the murder of his brother, for the part he played in the reign of terror which followed the collapse of Athens. "Against Agoratus" (xiii; *Kata Agoratos*) also gives interesting information about the activities of the Thirty. Other speeches concern various crimes against the state; e.g., murder (i), malicious wounding (iii and iv), sacrilege (v and vii) and taking bribes (xxi). One is in prosecution of the public corn dealers for overcharging (xxii), and a particularly delightful speech defends a cripple's right to a state pension (xxiv). Three concern the scrutiny of persons elected to public offices (xvi, xxvi, xxxi). A few of the extant speeches were written for private suits, such as x in which a man is accused of slander. The most interesting of the papyrus fragments come from a speech in which the point at issue is apparently the recovery of Lysias' property which had been confiscated by the Thirty.

In contrast with the self-conscious artistry of Antiphon, Lysias' style in his legal speeches is unpretentious and achieves its effect by its apparent artlessness. This was in keeping with the trends of his time. About the end of the 5th century there was a reaction, at least as regards practical oratory, against the artificial embellishments of Gorgias and his imitators. Juries were inclined to suspect the sincerity of an elaborately composed speech. No speech writer was more successful than Lysias in disarming such suspicions. His language reflects the simple speech of everyday life. Rare and poetical words, colourful metaphors, striking phrases are all avoided. Of the so-called "figures of speech," antithesis is the only one commonly found, and even this he uses in moderation and with regard to the appropriateness of the context. The structure of his sentences is remarkably supple and varied; he ranges with complete mastery from the short, uncompounded sentence to the complex, rounded period. His arrangement of subject matter is clear and precise. Speeches are normally divided into introduction, narrative of facts, proofs and epilogue. His characteristic qualities are best seen in the narrative. Introduction and epilogue are inevitably to some extent conventional, but he shows great skill in varying them so that each is appropriate to the particular speech.

What contributed as much as anything else to Lysias' success as a speech writer was his unrivaled genius for making his speeches reflect the character of the speakers. Notable examples are the speeches written for the ingenuous young knight Mantitheus (xvi) and the humorous, but unscrupulous, cripple (xxiv). "Against Eratosthenes" shows that Lysias was capable of impassioned oratory when he himself was the speaker and his own feelings were deeply involved, but in his professional writing for the courts the tone is quiet and there is little appeal to the emotions.

Lysias' influence on subsequent Greek prose was considerable. With later antiquity he became the model for the plain style of Attic Greek.

LYSIMACHUS (c. 355–281 B.C.), Macedonian general, satrap and king, was one of the "Successors" (Diadochi) of Alexander the Great. He played an important role in the wars which followed Alexander's death and in the political transformation of the Macedonian empire thereby effected. During Alexander's conquest of the Persian empire Lysimachus

was one of the king's bodyguard. He distinguished himself in the Indian campaign. In the distribution of satrapies at Babylon after Alexander's death (323) he was given Thrace to govern. For many years he was fully occupied in wars against the native peoples there and so prevented from taking an active part in the struggles in Greece and Asia between the other Successors, though in 316 he joined with Cassander, Ptolemy and Seleucus in the coalition against Antigonos I. It was not until 302, on the occasion of the second alliance of the enemies of Antigonos, that he emerged as a power of the first rank. Then, reinforced by troops given him by Cassander, he entered the dominions of Antigonos in Asia Minor and bore the brunt of the campaign which ended in the overthrow of Antigonos at the battle of Ipsus (301; *q.v.*). The division of Antigonos' kingdom resulted in Lysimachus' acquiring the greater part of Asia Minor. This, with his European possessions, gave him a position of great strategic strength; his territory at its greatest extent embraced about 160,000 sq.mi. He had taken the title of king at the same time as the other Successors in 306/305, having already built himself a new capital, Lysimachia, in the Thracian Chersonese (Gallipoli peninsula) near the older city of Cardia (309).

After 301 Lysimachus consolidated his power in both Asia and Europe in wars against Demetrius Poliorcetes. Only in 294 did he conclude peace, having by then annexed the cities in Ionia and Caria which Demetrius had retained after Ipsus. An attempt to carry his power beyond the Danube ended in failure, but in 288 he joined hands with Pyrrhus, the king of Epirus, to drive Demetrius from Macedonia. Pyrrhus was at first allowed to remain in possession of half of Macedonia with the title of king, but in 285 Lysimachus seized the whole country for himself.

The last years of his life were darkened by dissension and intrigue within the ranks of his family. He had married as his third wife Arsinoe, the daughter of Ptolemy I Soter, the king of Egypt. This ambitious and ruthless woman, in order to gain the succession for her own sons (and probably at the instigation of her half brother Ptolemy Ceraunus, who had left Egypt to seek his fortune with Lysimachus), persuaded her husband to execute his eldest son Agathocles on a charge of treasonable conspiracy with Seleucus I, the Syrian king (284). This unjustified act caused revulsion among the courtiers and throughout the kingdom. Agathocles' widow fled to Seleucus, who, seeing the prevailing discontent, took advantage of the opportunity to invade the territory of Lysimachus in Asia Minor, where many of the Greek cities had already revolted. Lysimachus crossed the Hellespont into Asia, and in 281 a decisive battle was fought at Corupedium in Lydia in which Lysimachus was defeated and killed.

Lysimachus was an able and energetic ruler. In generalship and statesmanship he was fully the equal of the other Successors. Over the Greek cities in his realm he exercised a strict control, taxing them heavily. One aspect of the close attention he gave to the financial organization of his kingdom may be seen in the extremely fine coinage bearing the head of Alexander which he issued and which served as a model to be copied by other kings long after his death.

See F. Geyer in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. xiv, 1–31 (1928). (R. H. St.)

LYSIPPUS (fl. late 4th century B.C.), Greek sculptor, was head of the school of Argos and Sicyon in the time of Philip and Alexander of Macedon. He worked in bronze and was said to have produced some 1,500 works, several of them colossal. He modified the canon of Polyclitus toward a more slender type, and introduced an element of impressionism. Lysippus represented the acme of lifelike naturalism. Pliny and other writers mentioned many of his statues. Among the gods he seems to have produced new and striking types of Zeus, Poseidon, the sun-god Helios and others. He made several statues of Hercules, stressing the motif of weariness exemplified in the later Farnese Hercules.

Lysippus made many portraits of Alexander the Great and became the court sculptor of the king, from whom and from whose generals he received many commissions. The extant portraits of Alexander vary greatly and it is impossible to determine which among them go back to Lysippus.

As head of the great athletic school of the Peloponnese, Lysippus sculptured many athletes; a figure by him of a man scraping himself with a strigil (skin scraper) was a great favourite of the Romans in the time of Tiberius; and this has been usually regarded as the original copied in the Apoxyomenus of the Vatican. More than 40 ancient copies of his "Eros" exist. His "Kairos," a personification of opportunity, has often been imitated. He also did drunken flute players and dancing satyrs.

See F. P. Johnson, *Lysippos* (1928); M. Bieber, *The Sculpture of the Hellenistic Age*, pp. 38-39 (1955). (P. G.; D. M. R.)

LYSIS OF TARENTUM (fl. c. 400 B.C.), Greek philosopher, a member of the Pythagorean community in southern Italy, is said to have escaped from a massacre there to Thebes, where he became the teacher of Epaminondas. A letter of his, whose genuineness is doubtful, is given in Iamblichus, *Life of Pythagoras*, 75-78.

LYTE, HENRY FRANCIS (1793-1847), English clergyman and hymn writer, was born near Kelso on June 1, 1793, and was educated at Enniskillen school and at Trinity college, Dublin. He took orders in 1815, and eventually settled, in 1823, in the parish of Brixham. He died at Nice on Nov. 20, 1847.

Lyte is remembered for his *Poems*, chiefly *Religious* (1833) and *The Spirit of the Psalms* (1834). His best-known hymns are "Abide with me!"; "Jesus, I my cross have taken"; and "Praise, my soul, the King of Heaven."

LYTHAM ST. ANNES, a municipal borough (1922) and popular seaside resort of Lancashire, Eng., is situated on the northern side of the Ribble estuary, 12 mi. W. of Preston and adjoining the southern boundary of Blackpool. Pop. (1961) 36,222. There are five public parks, extensive floral promenades and 6½ mi. of beach. Four 18-hole golf courses include the Royal Lytham and St. Annes Golf club, venue of national and international golfing events. Squire's Gate airport, between Lytham St. Annes and Blackpool, has services to the European continent, Jersey and the Isle of Man. A Benedictine cell was founded at Lytham in the 12th century by Richard Fitz-Roger, lord of the manor.

(T. J. H.)

LYTHRACEAE, the loosestrife family of flowering plants, consisting of about 23 genera and 475 species of dicotyledonous herbs, shrubs or trees, widely distributed but abundant in the American tropics. They have mostly opposite, entire leaves, with stipules minute or lacking; and flowers bisexual, mostly axillary, solitary or in clusters, generally symmetrical, with the calyx free from the ovary and petals sometimes wanting. Among the best-known ornamental members are crape myrtle (*Lagerstroemia*), spiked or purple loosestrife (*Lythrum*), cigar flower (*Cuphea*) and henna (*Lawsonia*). See LOOSESTRIFE; HENNA. (J. M. BL.)

LYTTON, EDWARD GEORGE EARLE LYTTON, BULWER-LYTTON, 1ST BARON (1803-1873), prolific and versatile English novelist and politician, was born in London on May 25, 1803, the youngest son of Gen. William Bulwer and Elizabeth Lytton, the heiress of Knebworth, Hertfordshire. His father died when he was four, and Bulwer was educated at various private schools and at Trinity college and Trinity hall, Cambridge. While still at school he published *Ismael, an Oriental Tale* (1820), a volume of youthful Byronic verses, and was deeply affected when the young girl with whom he had fallen in love was abruptly removed by her father. Their brief romance and her subsequent death profoundly influenced Bulwer's attitude to love in his novels. While at Cambridge he was awarded the Chancellor's medal for his poem *Sculpture* (1825), and was drawn into a flirtation with Lady Caroline Lamb, Byron's former mistress. He then visited Paris and Versailles, and on his return to England met Rosina Doyle Wheeler, an Irish beauty, whom he married in 1827. His mother disapproved of the match and as a final protest withdrew his allowance.

Bulwer was thus forced to find some means of earning a living. He had already published *Falkland* (1827), an unpopular novel heavily influenced by Jean Jacques Rousseau and Mrs. Ann Radcliffe, but *Pelham* (1828), the adventures of a young dandy in the fashionable world, was a great success and inaugurated his career as a fluent popular novelist. His extravagant style of living necessitated feverish industry and the strain made Bulwer an irritable and negligent husband. Rosina became jealous of his work, and

after a series of increasingly violent quarrels, they were legally separated in 1836. But Rosina's hysterical passion was not appeased, and she was a constant source of embarrassment to Bulwer for the rest of his life.

In 1831 Bulwer entered parliament as Liberal member for St. Ives and in 1832 became member for Lincoln. He advocated legislation on behalf of literature and the arts, including a reduction in the newspaper tax and the creation of dramatic copyright, attacked censorship, and recommended state subsidies for the theatre. His pamphlet in support of Lord Melbourne in 1834 was said to have been instrumental in returning a Whig government. As a reward he was offered a minor post which he refused in favour of his literary career, and in 1841 he retired in protest against the repeal of the corn laws. This, together with his growing friendship with Disraeli, converted Bulwer into a Tory, and in 1852 he returned to the house as member for Hertfordshire. He was created a baronet in 1838, added Lytton to his surname when he inherited Knebworth in 1843, and was raised to the peerage as Baron Lytton of Knebworth in 1866. He was not active in the house of lords. He died at Torquay on Jan. 18, 1873.

Bulwer's interest in the theatre was not confined to legislation. His own theatrical ventures were the result of his friendship with William Macready (q.v.), the celebrated actor-manager, who, together with John Forster (q.v.), Bulwer's staunchest literary friend, shaped his plays by encouragement and criticism. His first production, *The Duchess de la Vallière* (1836), was a failure, but *The Lady of Lyons* (1838), a romantic comedy, and *Richelieu* (1839), a historical comedy with Macready in the title role, were great successes. *Money* (1840), a social comedy and Bulwer's most enduring play, was to be his last, for the theatre was not really profitable, and despite his many plans nothing else was completed.

Bulwer's versatility was also shown in several volumes of poetry including *The New Timon* (1846), a satirical verse novel which contained an unworthy attack on Tennyson, and *King Arthur* (1848), an ambitious and unsuccessful long epic. He also edited the *New Monthly* (1831-33), wrote *England and the English* (1833), an acute piece of social criticism, and a history of Athens, but his literary reputation rests primarily on his novels. His immense popularity during his lifetime was largely due to his skill in anticipating and satisfying the various changes in public taste. Thus he started in the "Silver Fork" tradition with *Pelham*, which combined Gothic romance with the setting of the fashionable world; in *Devereux* (1829) he began a series of historical novels which included the spectacularly successful *The Last Days of Pompeii* (1834), *The Last of the Barons* (1843), and *Harold, the Last of the Saxon Kings* (1848); and in *Paul Clifford* (1830) and *Eugene Aram* (1832) he made use of the current interest in criminals and the underworld. Bulwer's own interest in the occult produced *Zanoni* (1842) and *A Strange Story* (1862); he presented his Utopia in *The Coming Race* (1871), and turned to realism and the portrayal of English society in *The Caxtons* (1849) and *My Novel* (1853).

In the 20th century Bulwer-Lytton's reputation has declined as sharply as the critics (including Thackeray) who persecuted him in *Fraser's Magazine* could have wished. He was influenced by the romanticism of Byron and Goethe, the melodrama of the Gothic novel, and by such novelists as Samuel Richardson, Henry Fielding and William Godwin. His plots are elaborate and involved and his characterization is exaggerated and unreal. Thus his heroines are all purity and sweetness and his villains as unscrupulous as they are unscrupulous. His historical novels tend to be weighed down with meticulous detail, and his style is grandiose and ornate. Without the instinctive genius of a Dickens or a Thackeray which could triumph over the sentimental ideals of the period, he is an inescapably dated writer, although a gifted storyteller who remains immensely readable. In his best novels such as *Ernest Maltravers* (1837) and its sequel *Alice* (1838), the strong autobiographical element provides a convincing and revealing portrait of society, life and the political arena. His personal experience of society and politics gives Bulwer's work historical interest: his standing is that of a talented novelist in the great age of the novel.

LYTTON, (EDWARD) ROBERT BULWER-LYTTON, 1st EARL OF (pseudonym, OWEN MEREDITH) (1831-1891), English diplomat, and a notable viceroy of India (1876-80) who also achieved a considerable contemporary reputation as a poet. The only son of the first Lord Lytton (*q.v.*), he was born in London on Nov. 8, 1831. Although he wished to become a poet, his father insisted that he should enter the diplomatic service. After three years at Harrow (1846-49), and a year with a tutor in Bonn, in 1850 he was appointed unpaid attaché to his uncle, Sir Henry Bulwer (later Lord Dalling, *q.v.*), then minister at Washington, D.C. He rose steadily in the service, his first paid appointment being at Vienna (1858), and in 1874 was appointed minister at Lisbon. In 1864 he had married Edith Villiers, niece of the earl of Clarendon, and in 1873 had succeeded to the barony.

In Nov. 1875 Disraeli asked him to succeed Lord Northbrook as governor-general of India. Relations with Afghanistan were in a delicate state; Russian influence there was growing, and Lytton took with him orders either to counteract it or to secure a stronger frontier by force. Eleven months of negotiations had produced no result when he abruptly suspended them in March 1878; his actions led to war with Afghanistan in November. The British forces won a quick victory. The amir, Sher Ali Khan, fled and his son Yakub Khan was installed in his place. The treaty of Gandamak (May 26, 1879) established a more defensible "scientific" frontier with India as well as a British residency at Kabul to control Afghan foreign policy. (*See AFGHANISTAN: History.*) But on Sept. 3 the resident, Sir Pierre Louis Cavagnari, and his staff were murdered and war began again. Lytton immediately dispatched Gen. Sir Frederick (later Field Marshal Earl) Roberts on a successful campaign, which was still being pursued when the governor-general resigned, with the Conservative government, in the spring of 1880. His successor, Lord Ripon, disapproved and revised his "forward" Afghan policy. Though Afghanistan received most attention in Great Britain during Lytton's viceroyalty, and his conduct there was criticized, he had done much for Indian administration: he supervised effective measures for famine relief, abolished internal customs barriers, decentralized the financial system, proclaimed the queen empress of India at a splendid durbar at Delhi (Jan. 1,

1877) and reserved one-sixth of civil service vacancies for Indians.

On returning from India, Lytton received an earldom, and in 1887 was appointed ambassador in Paris, where his winning personality did much to improve Anglo-French relations. He died there, very suddenly, on Nov. 24, 1891, and was succeeded by his elder surviving son, Victor (1876-1947), under-secretary of state for India (1920) and governor of Bengal (1922-27). On his death the title passed to his brother Neville Stephen (1879-1951), who was succeeded by his son, Noel Anthony Scawen (1900-).

To his contemporaries, Robert Lytton was better-known as a poet than as a diplomat, and his first collections—*Clytemnestra . . . and Other Poems* (1855), verse narratives imitative of Browning; *The Wanderer* (1858), autobiographical lyrics—were well received, as was *Lucile* (1860), a witty and romantic novel in verse. His undoubted talents were encouraged by the Brownings, whom he met in Florence (1852), by his father's friend, John Forster, and by Charles Dickens. They suffered, however, from his inability to give writing his undivided attention, and success as a diplomat prevented his poetic development. The failure of *Chronicles and Characters* (1867), an ambitious attempt to express poetically the ideas of the past, depressed him deeply and, when he returned from India, he found that his creative energies had been exhausted by long suppression. In *Glenaveril; or, the Metamorphoses* (1885), a long verse narrative of considerable power and poetic beauty, he dramatized the inner conflict which had prevented his achieving a consistent style and viewpoint. *After Paradise; or, the Legends of Exile . . .* (1887) and *Marah* (1892) collected his later lyrics, and in *King Poppy* (1892), a satirical allegory, he criticized with wit and delicate fantasy the Victorian materialistic philosophy. He also published (1883) two volumes of the *Life, Letters and Literary Remains* of his father, ending in 1831.

D. F.; X.)

M THE letter M corresponds to the Semitic \aleph (*mem*) and to the Greek μ (*mu*). The Semitic form may derive from an earlier sign representing waves of water. Early Greek forms from Thera, Attica and Corinth closely resemble the early North Semitic \aleph , \aleph . The Lydian alphabet also had the form \aleph . These forms differ only in the direction of the writing. The Etruscan form was similar, but with an additional stroke, \aleph . The Ionic alphabet had the form μ . Since this form is rare in Etruscan, the Latin form M may have been borrowed directly from the Chalcidian.

Curious forms occurred in the various Italic alphabets. Umbrian had \aleph or \aleph , Oscan \aleph , Faliscan \aleph . The rounded form appeared in the uncial writing of the 5th or 6th centuries, \aleph . The cursive hands of the 6th century showed \aleph and on this was based the Carolingian \aleph . The modern minuscule does not differ essentially from the majuscule letter. The sound represented by

THE DEVELOPMENT OF THE LETTER "M" FROM THE PHOENICIAN THROUGH CLASSICAL LATIN TO THE PRESENT FORM

the letter has been from the beginning the labial nasal. The nasals of all sounds are least liable to change, a fact that is reflected in the consistent history of the letter. See also ALPHABET.

(B. F. C. A.; J. W. P.)

MA'AN, a town of southern Jordan, administrative centre of the *liwa'* (district) of that name. Pop. (1961) 6,643. It lies on a plateau at the fringe of the desert and is the trading and shopping centre for the Bedouin who are the principal inhabitants of the area. The town, built almost entirely of mud brick, is linked by road and rail to Amman and by road to the port of Aqaba. There is a landing strip east of the town. Ancient Petra (*q.v.*) lies 25 mi. W., and from Ra's an Naqb on the south there is one of the most sensational views in the country.

MA'AN LIWA' includes the subdistricts of Aqaba and Ma'an. Area 266 sq.mi. Pop. (1961) 46,914. Much of the district is a high plateau. It is sparsely cultivated. (G. W. L. H.)

MAAS, NICOLAS: see MAES, NICOLAES.

MAASTRICHT, the capital of Limburg province, the Netherlands, on the left bank of the Maas (Meuse), 32 km. (20 mi.) N.N.E. of Liège, Belg., by road. Pop. (1960) 90,633. Maas-tricht, the site of a Roman settlement, was the seat of a bishop from c. 382 to 721. After 1204 the duke of Brabant held the town in fief from Philip of Swabia; in 1284 it came under the joint sovereignty of Liège and Brabant and in 1632 of Liège and the Dutch states-general. In 1579 it was taken and plundered by the Spaniards under the duke of Parma. It became a strategic fortress and was besieged by the French in 1673, 1748 and 1794. Parts of the old fortifications—Hellgate (1229), fort of St. Peter and 16th-18th-century bastions—remain.

The suburb of Wijk lies on the right bank of the river. A stone bridge, St. Servaasbrug, connecting the two sections, replaced a wooden structure as early as 1280 and was rebuilt in 1683; the Wilhelminabrug was completed in 1934. The town hall (1659-64) contains paintings and Gobelins. The Dinghuis, or former courthouse, is a 15th-century Gothic building. The church of St. Servatius (St. Gervase), founded by Bishop Monulphus in the 6th century, is the oldest church in Holland; according to one account it was rebuilt and enlarged from the 11th to the 15th century. The late Romanesque basilica of St. Mary (Onze-Lieve-Vrouwekerk) has two ancient crypts and a 12th-century choir. The Protestant St. Janskerk, a Gothic building of the 13th and 15th centuries, with a fine tower, formerly served as the parish church for the cathedral of St. Servatius. There are also many fine houses in regional Renaissance and French styles. Maastricht is a noted art and cultural centre with a music conservatory, symphony orchestra, men's choir, academies of drama and plastic arts, and museums of antiquities and natural history.

An early trade was carried on in cloth, leather, hardware and building materials. The town did not reap the full advantages of its central position between the mining and industrial cities of Heerlen, Aix-la-Chapelle, Liège and Kempen till the opening of the railways after 1853. There are now manufactures of pottery, glass and crystal, as well as cement, paper, tobacco and cigar factories. Steel and chemicals are produced and art-printing is significant. There is a trade in grain and butter.

A short distance south of Maastricht are the marl quarries of Pietersberg, which were worked from Roman times till the end of the 19th century, resulting in more than 200 mi. of subterranean labyrinths, now partly leveled by the cement industry. In the time of the Spanish wars these underground passages served to hide the peasants and their cattle, and during World War II famous art treasures were stored there. The Renaissance castles of Neubourg and Mheer, the baroque castle of Amstenrade and the late-17th-century castle of Neercanne are nearby. Maastricht was assaulted by the Germans on May 10, 1940—the first day of the invasion of the Low Countries—and was liberated Sept. 13-14, 1944. (J. G. J. K.)

MABILLON, JEAN (1632-1707), Benedictine monk and scholar of the Congregation of St. Maur, was born on Nov. 23 1632, the son of a peasant living near Reims, France. In 1653 he entered the abbey of St. Remi at Reims and in 1664 was placed at St. Germain-des-Prés in Paris, the great literary workshop of the Maurists. There he lived and worked for 20 years, at first under Luc d'Achéry, with whom he edited the nine folio volumes of *Acta of the Benedictine saints* (1668-1701). In Mabillon's prefaces (reprinted separately) these lives were for the first time made to illustrate the ecclesiastical and civil history of the early middle ages.

Several journeys—in Flanders, Lorraine, Burgundy, southern Germany and Switzerland—proved exceptionally fruitful. Many of Mabillon's discoveries were promptly published in his *Vetere Analecta* (4 vol., 1675-85). Prompted by the excessive skepticism

of the Jesuit Daniel Papebroch, who in his *Propylaeum antiquarium circa veri ac falsi discrimen in vetustis membranis* (1675) had declared that nearly all Merovingian documents were spurious and that no authentic charters existed for the period before 700, Mabillon with the help of several of his confrères produced a classic work, his *De re diplomatica* (1681; supplement, 1704), in which were first laid down the principles for determining the authenticity and date of medieval charters and manuscripts. It practically created the science of Latin paleography. Work on the *Lectioary* of Luxeuil, discovered in the early days of the *Iter Germanicum* (1683), stimulated him to write the *De liturgia Gallicana* (1685), and the most profitable journey of all, that in Italy, led to the publication of the *Museum Italicum* (1687-89), which included not only the famous Missal of Bobbio but also the precious *Ordines Romani*. These important texts have been splendidly re-edited since, but for more than two centuries they were the only resource available to scholars. On his return to Paris from Italy Mabillon was called upon to defend against the Trappist abbot A. J. le B. de Rancé, the legitimacy for monks of the kind of studies to which the Maurists devoted themselves. This called forth Mabillon's *Traité des études monastiques* and his *Réflexions sur la réponse de M. l'abbé de la Trappe* (1691-92), works embodying the ideas and program of the Maurists for ecclesiastical studies. Mabillon produced in all about 20 folio volumes and as many of lesser size, nearly all works of monumental erudition. He died in Paris on Dec. 27, 1707, in the midst of the production of the colossal Benedictine *Annales* (4 vol., 1703-07; vol. 5, posthumously, 1713; vol. 6, the work of other authors, 1739). See also DIPLOMATIC.

BIBLIOGRAPHY.—The chief authority for Mabillon's life is the *Abrégé de la vie de D. J. M.* (also in Latin), by T. Ruinart (1709), reprinted (1933) under the title *Mabillon* (Collection *Pax*, xxv). See also R. P. Tassin, *Histoire littéraire de la congrégation de St. Maur* (1770). Excellent introductions to the study of Mabillon's career are the articles by J. Baudot in *Dictionnaire de Théologie catholique*, vol. ix, and by H. Leclercq in *Dictionnaire d'Archéologie chrétienne et de Liturgie*, vol. x. The modern biographies include those of E. de Broglie, 2 vol. (1888), S. Bäumer (1892) and Henri Leclercq, 2 vol. (1953-57), this last work in many respects the most valuable of all. Especially useful is J. U. Bergkamp's dissertation, *Dom Jean Mabillon and the Benedictine Historical School of Saint-Maur* (1928).

(E. C. B.; AM. S.)

MABINOGION, THE, the title of a collection of 11 medieval Welsh tales. *The White Book of Rhydderch* (c. 1300-25) is the first manuscript extant to contain any considerable number of them; *The Red Book of Hergest* (c. 1375-1425) the first to contain them all. The form *mabinogion* was long regarded incorrectly as a plural of *mabinogi*, which meant, first "youth," then "a tale of youth" and lastly "a tale." The stories of the *Mabinogion* are (1) "The Four Branches of the *Mabinogi*," consisting of "Pwyll Prince of Dyfed," "Branwen daughter of Llŷr," "Manawydan son of Llŷr" and "Math son of Mathonwy"; (2) the native Arthurian tales "Culhwch and Olwen" and "The Dream of Rhonabwy"; (3) "The Dream of Macsen Wledig" and "The Adventure of Lludd and Llefelys"; and (4) the French Arthurian romances "Owain and Luned" (or "The Lady of the Fountain"), "Geraint and Enid" and "Peredur son of Efrog." These anonymous tales, taken from oral stories, are based on mythology, folklore, heroic traditions and etiological elements and range from the second half of the 11th century to the close of the 13th century.

(T. Js.)

MABUSE (MALBODIUS), **JAN** (JAN GOSSAERT OR JENNI GOSSART) (c. 1478-1532), was the name adopted (from Maubeuge in northern France, where he or his family originally came from) by the Flemish painter Jan Gossaert. He is most likely to be identified with the Jennyn van Hennegouwe who registered as master in the guild of St. Luke at Antwerp in 1503. His most important early work extant is the "Adoration of the Kings" in the National Gallery, London, which is signed by him. There he throws together some 30 figures on an architectural background, carefully elaborated and Romanesque in style. He surprises us by pompous co-

tume. His figures, like pieces on a chessboard, are often rigid and conventional. The landscape which shows through the ruined architecture is adorned with towers and steeples in minute fashion. This picture, probably painted for the abbey of St. Adrian, Grammont, is the work of a man trained in the old Flemish traditions.

That he was an admirer of Jan van Eyck is shown by his picture in Madrid of "Jesus, the Virgin and the Baptist," in Gothic framework. One of Mabuse's most distinguished works, the little triptych at Palermo was probably also painted at this early period. Jean Carondelet, who was Mabuse's patron, was archbishop of Palermo and chancellor of Flanders, and he probably transferred the picture to Sicily. It is a wonderful piece of pictorial elaboration, containing features taken from Dürer. Another early work is the moonlight scene representing "The Agony in the Garden," in the Berlin museum.

After living for a few years at Antwerp, Mabuse took service with Philip, bastard of Philip the Good, at that time lord of Somerdyk and admiral of Zeeland. One of his pictures had already become celebrated—a "Descent From the Cross" with 50 figures, ordered by Philip of Burgundy for the high altar of the church of Middelburg; and the value which was then set on the picture is apparent from the fact that in 1521 Dürer came expressly to Middelburg to see it, noting in his diary that it was not so good in design as in execution. In 1568 the altarpiece perished by fire. A smaller "Descent From the Cross," seen by Van Mander at Delft, is probably the one now in the Hermitage at Leningrad. In 1508 Mabuse accompanied Philip of Burgundy on his Italian mission, and this led to an important revolution in the art of the Netherlands. Mabuse not only brought home a new style, but also introduced the fashion of traveling to Italy; and from that time until the age of Rubens and Van Dyck it was considered proper that all Flemish painters should visit the peninsula.

In the summer of 1509 Philip returned to the Netherlands, and, retiring to his seat of Suytburg in Zeeland, surrendered himself to the pleasures of planning decorations for his castle and ordering pictures from Mabuse and Jacopo de Barbari. Being in constant communication with the court of Margaret of Austria at Malines, he gave the artists in his employ fair chances of promotion. Barbari was made court painter to the regent, while Mabuse received less important commissions. Records prove that Mabuse painted a portrait of Leonora of Portugal, and other small pieces, for Charles V in 1516. But his only signed pictures of this period are the "Neptune and Amphitrite" of 1516 at Berlin, the composition of which is taken from Dürer's famous engraving, and the Madonna, with a portrait of Carondelet of 1517, at the Louvre. In these last two we clearly discern that Giorgio Vasari only spoke by hearsay of the progress made by Mabuse in "the true method of producing pictures full of nude figures and poesies," for the types are ugly, though drawn delicately and modeled elaborately. Of similar type is the "Hercules and Deianira," dated 1517, in the Barber institute, Birmingham. In later forms of the same subject—the "Adam and Eve" at Hampton court, or the other version at Berlin—we observe more nudity, combined with realism.

Mabuse's "St. Luke Painting the Portrait of the Virgin" in the Narodni Galerie at Prague, and a variety of the same subject in the Vienna museum, prove that travel had left many of Mabuse's fundamental peculiarities unaltered. His figures still retain the character of stone; his architecture, now in Italian Renaissance style, is as rich and varied; his tones are as strong as ever. But bright contrasts of gaudy tints are replaced by soberer grays, and a cold haze pervades the surfaces. In this form the Madonnas of Munich (1527) and Vienna, in the collections of Max Wassermann in Paris, and E. Simon in Berlin, are fair specimens of his skill.

As early as 1523, when Christian II of Denmark came to Belgium, he asked Mabuse to paint the likenesses of his dwarfs. In 1528 he requested the artist to suppress the design for his Queen Isabella's tomb and epitaph in the Abbey of St. Pierre near Ghent. It was no doubt at this time that Mabuse completed the portraits of John, Dorothy and Christine, children of Christian II, of which replicas are at Hampton court, at Wilton house and at Longford castle, Wiltshire. It is as a portrait painter that Mabuse can be

seen to the best advantage. His portraits of Carondelet in the collection of M. von Guttman in Vienna and L. Hirsch in London; of Marquise de Vere in the Gardner museum at Boston, Mass., and others in the galleries of Copenhagen, London, Paris, Berlin, and in the Pratt collection, New York city, are remarkable for their strength and plasticity. In his later portraits the rendering of the hands becomes remarkably expressive of the sitter's personality. Carondelet's portrait in Vienna formed part of a diptych. The opposite wing is now in the Tournai museum and carries a half-length of St. Donatian. This diptych is one of the most powerful works of Mabuse.

When Philip of Burgundy became bishop of Utrecht, and settled at Duerstede, near Wyck, in 1517, he was accompanied by Mabuse, who helped to decorate the new palace of his master. At Philip's death, in 1524, Mabuse retired to Middelburg, where he took service with Philip's nephew, Adolph, lord of Veeren. He died at Breda in 1532.

MAC (Scottish and Irish Gaelic *mac* = "son") is a surname prefix equivalent to the Anglo-Norman and Hiberno-Norman *Fitz* and the Welsh *Ap* (formerly *Map*). Just as the latter has become initial *P*, as in the modern names Price, Pritchard, etc., *Mac* has in some names become initial *C* and even *K*; e.g., Cody, Costigan, Keegan.

The Gaelic countries were among the earliest to adopt hereditary surnames, their introduction in Ireland dating from the 11th century (with a few early ones in the 10th). A cursory examination of early medieval Gaelic records gives the impression that surnames in the modern sense were in use much earlier, because such personal names as *Domhnall Mac Gormain* occur continually; this name, however, does not in fact imply the existence of the surname MacGorman in the 9th century but merely indicates that this *Domhnall* (Donnell) was the son of a man whose Christian name was Gorman. Similarly, Dermot O'Tierney was simply Dermot the grandson of a man called Tierney (*Ua*, later shortened to *O*, means grandson or, more loosely, descendant).

Most names in *Mac* are formed from a Christian name, as is *Mac Aonghusa* (modern MacAinsh or MacGuinness, which both derive from the forename now anglicized as Angus). Many have been still farther removed from their original form by the substitution of the terminal *-son* for the prefix *Mac*; e.g., Ferguson. Several of the best known *Mac* names embody Norse forenames, e.g., the Scottish MacCorquodale, the Irish MacManus, or Irish MacLoughlin (MacLachlan in Scotland). Later, Norman names were likewise incorporated, e.g., MacCostello; and in more recent times, especially in Scotland, surnames like MacDicken and MacRitchie have been formed from modern Christian names.

Most English surnames are formed from trades, personal attributes and places. The first two categories occur also in the Gaelic system, though less frequently. Instances are: MacDuff; Duffie (and even MacPhie, all from *dubh*, "black"); and Macateer (*mac an t-saoir*, "son of the carpenter," often translated to give Carpenter). Place names, naturally, do not combine readily with *Mac*.

In Gaelic Scotland there are now no *O* names. Ogilvie is a toponym (i.e., a place-name derivation). Usually *-Gill-* here is *giolla*, "follower" or "devotee" (usually associated with Christ or with the name of some saint, e.g., Gilchrist). It is rare with *O* but frequent with *Mac*, as, for example, in MacElroy, MacIlwaine, MacLennan, MacClellan. There are numerous modern, anglicized forms of names beginning in Gaelic with *mac giolla*; e.g., *Mac Giolla Riabhaigh*, which gives MacGillreavy, MacGilrea, MacElreavy, MacIlrea, MacAreavy, MacIlravy, MacElreath, MacIlwraith, Gallery, occasionally Kilgray and even Gray, as well as other minor variants. Indeed, some of the more corrupt forms of such names bear little resemblance to their original: it is hard to recognize *Mac Giolla Bhrighde* ("son of the devotee of St. Brigid") in Mucklebreed (a synonym of MacBride in County

Armagh). Meikleham for MacIlquham is a Scottish example of this.

MacAinsh, mentioned above, is an anglicized form approximating phonetically to the original Gaelic *Mac Aonghusa*; but in Scotland it has also become MacInnes, MacNeish and MacQuinness, while in Ireland it is MacGuinness.

This last name illustrates a tendency, particularly in Ulster, whereby *Mac* names followed by an initial *G* are contracted; thus MacGuinness (also written MacGennis) becomes Magennis, MacGuire becomes Maguire and MacGee, Magee.

In Ulster the *Mac* names outnumber the *O*'s, largely on account of the number of families of Scottish stock which settled there from the time of the plantation of Ulster early in the 17th century. Elsewhere in Ireland *O*'s outnumber *Mac*'s, although in one western county (County Clare) the two most numerous names are MacMahon and Macnamara.

A Macnamara in that locality is invariably known colloquially as Mac, and children of Macnamara families were sometimes formerly registered as Mack. The same abbreviation occurs to a lesser extent in other counties for different *Mac* names.

In Scotland the *Mac* prefix has been generally retained, but in Ireland, as a result of the Gaelic submergence in the 18th century, it was widely discarded, as was the cognate *O*: thus Carthy was used for MacCarthy, Keogh for MacKeogh, and so on. It is interesting to note that since the 1890s these prefixes have been resumed to a considerable extent.

If the popular illusion that the bearer of a *Mac* name is Scottish no longer exists (it is hard to know how it ever arose with names like MacMahon, MacCarthy and MacDermot so common), another fallacy dies slower; i.e., that the *Mc* form is Scottish and the *Mac* form Irish (sometimes the reverse is asserted). This is entirely without foundation. Both forms are used indiscriminately, *Mc* being, of course, simply an abbreviation of *Mac*, as also is *M'* (now nearly obsolete but once widely used). Most well-constructed modern indexes and directories list *Mac*, *Mc* and *M'* together.

MACÁ (formerly called ENIMAGÁ or ENI-MACÁ), a South American Indian tribe probably belonging to a Macá-Matacoan linguistic stock. Numbering at least 1,000 (1960s), they live on the plains between the Negro and upper Confuso rivers in the Gran Chaco, where they subsist by means of wild-food gathering, agriculture, hunting and fishing.

In the 18th century the Macá gained a reputation as fierce warriors, fighting against such tribes as the Mbayá and Guaná. At mid-20th century, aboriginal Macá culture was disappearing rapidly under the impact of white occupation of their territory.

Many Macá still live in long beehivelike communal houses covered with palm or grass thatch. The typical native dress was a deer or rhea-skin skirt for women and a dyed woolen blanket for men. Both garments were held in place by woolen belts woven in geometric designs.

Macá society characteristically consisted of small bands which joined seasonally to form larger communities at fishing spots and at locations where large quantities of algarroba pods could be harvested.

See Alfred Métraux, "Ethnography of the Chaco," Bureau of American Ethnology, *Bulletin* 143, vol. 1, pp. 197-370 (1946). (M. J. H.)

MACABRE: see DANCE OF DEATH.

McADAM, JOHN LOUDON (1756-1836), engineer who developed the macadam road, was born at Ayr, Scot., Sept. 21, 1756. In 1770 he went to New York city, entering the counting-house of a merchant uncle. He returned to Scotland with a considerable fortune in 1783, and purchased an estate at Saubrie, Ayrshire. The local highways were in poor condition, and McAdam, who was a road trustee in his district, began at his own expense a series of experiments in road making. In 1798 he moved to

Falmouth, where he continued his experiments under a government appointment. He recommended that roads should be raised above the adjacent ground for good drainage and covered with a surface of clean, graded stones. In 1815, having been appointed surveyor general of the Bristol roads, he was able to put his theories into practice. In 1819 he published a *Practical Essay on the Scientific Repair and Preservation of Roads*, followed, in 1820, by the *Present State of Road-making*. In 1827 he was appointed general surveyor of roads in Great Britain. McAdam died at Moffat, Dumfriesshire, on Nov. 26, 1836.

MACADAMIA, the generic and common name for the edible seeds of two closely related trees of the silk-oak family (Proteaceae; native to Queensland and New South Wales. Other names for the delicately flavoured, rich kernels are Queensland nut and Australian nut. *Macadamia ternstroemia* has stiff oblong-lanceolate leaves four to eight inches in length, with coarsely serrate margins; *M. integrifolia* has similar leaves, but with smooth margins. Under favourable conditions of growth (a climate about like that for the orange) and rather moist rich soil, the trees ultimately attain a height up to 60 ft. (18 m.) and are highly ornamental in appearance.

Hard-shelled, shiny round nuts, covered by thick husks and following the small white flowers, are abundantly produced on racemes six to eight inches long. The husks split open and release the nuts when the latter are fully ripe. The kernels, used almost exclusively as dessert nuts, bring high prices in food-specialty markets.

Propagation is commonly by seed, but superior varieties (of which a number have been established in Hawaii and Australia) must be propagated vegetatively. Grafting is commercially feasible but rather difficult. Because of their eventual large size, trees in orchards are planted 35 to 40 ft. (11 to 12 m.) apart. There are numerous small commercial orchards in Hawaii and Australia, many trees in California and Florida and occasional ones in other tropical and subtropical regions. (W. Po.)

McADOO, WILLIAM GIBBS (1863-1941), U.S. lawyer and railroad executive who served as secretary of the treasury and director-general of U.S. railroads during World War I. was born near Marietta, Ga., Oct. 31, 1863. He briefly attended the University of Tennessee, became deputy clerk in the U.S. circuit court at Chattanooga in 1882, and was admitted to the bar three years later. In 1892, disappointed with his law practice and the losses resulting from his efforts to modernize the Knoxville street railway system, he moved to New York city. There his main interest became transportation, and he organized and headed two companies (later consolidated as the Hudson and Manhattan Railway company) that built tunnels under the Hudson river and operated the railways connected with them.

McAdoo's abundant energy, his aptitude for politics, and a chance meeting with Woodrow Wilson led to his early participation in the movement to make Wilson president. His conspicuous part in the campaign and Wilson's confidence in him brought about his nomination as secretary of the treasury. In the cabinet he was one of the leading figures in the Wilson administration, gaining special recognition for his work connected with the federal reserve board, of which he was chairman, and for his service as director-general of U.S. railroads during the period of government operation (1917-19). Under his direction four successful Liberty bond drives were conducted. In 1919 he resumed the practice of law, first in New York and later in Los Angeles, Calif. Meanwhile, his first wife having died in 1912, McAdoo married Eleanor Randolph Wilson, daughter of the president, in a White House ceremony on May 7, 1914.

McAdoo emerged from public service as the acknowledged leader of a large segment of the Democratic party. He made a strong showing as a candidate for the presidential nomination at the party convention in San Francisco in 1920. His candidacy in New York in 1924, where a near majority of the delegates supported him, precipitated the famous deadlocked convention. He represented California in the U.S. senate from 1933 until his resignation in 1938.

He died Feb. 1, 1941. His career is well-documented by the

large collection of his personal papers in the Library of Congress. His autobiography, *Crowded Years*, appeared in 1931.

(J. C. V.)

MACAIRE, the title chosen by two successive editors, A. Mussafia and F. Guessard, for a French medieval epic romance, belonging to the Carolingian cycle, of which the only known manuscript is from the 14th century (Venice, Bibl. S. Marc, ms. fr. XIII). The title is derived from one of the chief characters in the romance, which relates what happens to Blanche fleur, wife of the old and infirm Charlemagne, when, having repulsed the advances of Macaire, she is accused of infidelity and condemned to death—a sentence commuted to perpetual exile. During this exile she is attended by the faithful Auberi de Mondidier who is assassinated by Macaire. He is avenged by his dog who, after saving Macaire in the midst of the royal court, discovers Auberi's corpse, engages in single combat with the murderer and kills him. Meanwhile Blanche fleur has reached Hungary, where she gives birth to Louis, Charlemagne's son; she then takes refuge with her father, the emperor of Constantinople. The emperor decides to avenge his daughter's honour and summons a powerful army to attack Charlemagne. The war ends with a single combat between Ogier the Dane (*q.v.*) and Varocher, the queen's protector; during the fight Varocher proves to Ogier that Blanche fleur is innocent, and Charlemagne, learning the truth, seeks and obtains his wife's pardon.

This story is also developed in another *chanson de geste* called *La Reine Sebile*, though details (the name of the queen, among others) differ. The manuscript of this, which runs to 500 lines, has been reconstructed from 13th-century fragments, discovered in England, at Mons, Belg., and at Sion in Switzerland. The poem also is known in a remarkably faithful Spanish translation, the manuscript of which (end of the 14th or beginning of the 15th century) is preserved in the Escorial, Madrid. This formed the basis of a Spanish prose romance, the *Historia de la Reyna Sevilla*, and of a book popular in the Netherlands, printed at Antwerp at the beginning of the 16th century; the story was already known there in the 14th century.

The existence of an epic romance on this subject was attested in France at least as early as the first half of the 13th century. Criticism remains in doubt as to whether *La Reine Sebile*, composed in dodecasyllabic verse, is earlier than *Macaire*, written in decasyllables; but it is generally admitted that these two romance poems developed almost identical stories independently. Whatever the facts of their origin, both are concerned with themes belonging to folklore: a queen unjustly suspected of infidelity and a dog who avenges his master's death. The first (see *GENEVÈVE*) is found, for instance, in the *Thousand and One Nights*, in Vincent de Beauvais's *Speculum majus*, and in a German poem of the 14th century, in which the queen is named Hildegard. The second, already with many of the details to be found in *Macaire*, is told in Plutarch's *Opera Moralia*, and the duel between Macaire and the dog is interpolated by Giraldu Cambrensis in a manuscript of the *Hexameron* of St. Ambrose. The name "*chien de Montargis*" is mentioned for the first time in the *Histoires prodigieuses* (1580) of François de Belleforest (1530-83), which asserts that the episode was depicted in a painting in the castle of Montargis. The story itself, again worked over by Gaston Phoebus in about 1390 and in the *Menagier de Paris* (1393), was thus already separated from its Carolingian context; Jean de la Taille, in his *Discours notable des duels* (1607), placed it in the reign of Charles V. See also *CHANSONS DE GESTE*; *CHARLEMAGNE LEGENDS*.

McALLEN, a city of Hidalgo county, in southeastern Texas, U.S., about 50 mi. W.N.W. of Brownsville and 7 mi. from the International bridge over the Rio Grande at Reynosa, Mex. It was founded in 1905, incorporated in 1911 and named for John McAllen, a Scottish settler from whose ranch the townsite was

carved. McAllen is a leading winter resort. It is the centre of oil-field operations in the Lower Rio Grande valley. McAllen is also a packing and shipping centre for an irrigated district devoted to citrus culture and vegetables, and a port of entry for trade with Mexico. Manufactures include clothing, food processing and petroleum products. For comparative population figures see table in TEXAS: *Population*. (O. Mo.)

MACALPINE (or **MACCABEUS**), **JOHN** (d. 1557), Scottish reformer and theologian, was from 1532 to 1534 prior of the Dominican convent of Perth; but having in the latter year been summoned with Alexander Ales and others to answer for heresy before the bishop of Ross, he fled to England, where he was granted letters of denization on April 7, 1537, and married Agnes Macheson, a fellow exile for religion; her sister Elizabeth became the wife of Miles Coverdale. The reaction of 1539 made England a doubtful refuge, and on Nov. 25, 1540, Macalpine matriculated at the University of Wittenberg, Ger. In 1542, having assumed the name of Maccabeus or Machabeus, he became professor of theology at the University of Copenhagen. There he took a prominent part in building up the Lutheran Church of Denmark. A joint exposure by Peter Plade and Macalpine of Andreas Osiander's errors was published in 1552 and reprinted at Leipzig and Copenhagen in 1768; and Macalpine was one of the four translators of Luther's German Bible into Danish. He died at Copenhagen on Dec. 6, 1557.

MACAO (Portuguese **MACAU**), a Portuguese overseas province on the coast of southern China, lies on the western side of the entrance to the Hsi Chiang (Si Kiang) river, opposite to and about 35 mi. from Hong Kong. It comprises the peninsula of Macao and three islets nearby, the two Taipa islands and Colôane, the area of the whole being about 6 sq.mi. On the peninsula, which is about 3 mi. long and 1 mi. broad, is situated the picturesque city of Macao, extending up a hillside to overlook a fine bay on the west. Its multicoloured buildings reveal an interesting combination of oriental and European features. Many fine buildings remain from early Portuguese times. The famous promenade, Praia Grande, is 1½ mi. long. The tropical climate is relieved by southwest sea breezes.

Direct trade by sea between Europe and China began through Portuguese enterprise as early as 1516. Macao, the oldest European outpost in the trade with China, was established in 1557. It was an early centre of Jesuit missionary activity and in 1580 the bishopric of Macao was created. In 1680 the first governor was appointed, but the Portuguese remained largely under the control of the Chinese with whom there were constant disputes concerning the extent of Portuguese jurisdiction. A rental was paid for the peninsula until 1849, when the Portuguese abolished the Chinese customhouse and declared the independence of the port. It was not, however, until 1887 that China formally rec-

ognized Portuguese sovereign rights in a treaty whereby China confirmed the perpetual occupation and government of Macao and its dependencies by Portugal, which in turn undertook never to alienate Macao and its dependencies without the consent of China, and to co-operate in the work of the opium revenue service. This did not put an end to disputes, and the delimitation of Macao's boundaries remained an unsettled question.

During the 18th century Macao was the chief centre in the Sino-European trade, but the rapid development of Hong Kong (ceded to Great Britain in 1842) was responsible for its decline, as also were the shallowness and silting of Macao harbour. The construction of an artificial deepwater harbour, begun in 1923, entailed the dredging of a 4-mi. channel to the open sea. These harbour works, completed in 1926 at a cost of \$10,000,000 (U.S.), led to the reclamation of 130 ac. of land on the eastern side of the peninsula, but the area remained largely unused. As a free port Macao remained a distribution centre for rice, fish, lumber, silk, piece goods and oil; but it also had a reputation for opium smuggling and gambling. League of Nations' efforts reduced its opium trade value from \$1,500,000 (U.S.) to about \$200,000 before 1939. In that year, after the capture of Canton and the closure of the Hong Kong-Kowloon border, Macao enjoyed briefly the available trade of southern China. From 1940 until the end of World War II Macao was subject to considerable pressure from the Japanese but it was never occupied.

The population, which rose from 83,894 in 1920 to 374,737 in 1940, and was swollen by refugees from Hong Kong in 1941, had fallen by 1960 to 169,299, including 7,974 Portuguese. By the mid-1960s the population was estimated at 250,000, including an unknown number of refugees from Communist China.

Rioting that broke out in Macao in December 1966, resembling the activities of the Red Guards in China, led to the deaths of several persons and injury of many others. Early in 1967, under pressure from Communist China, the Portuguese authorities accepted responsibility for the deaths and acceded to other Communist demands, including the barring of Chinese refugees.

Macao has an important fishing industry, much of the fish being salted or dried and exported, especially to China. The chief manufactures are textiles and apparel and firecrackers.

See L. G. Gomes, *Efemérides da história de Macau* (1954).

(L. D. S.)

MACAQUE, a name for monkeys of the large genus *Macaca*, mainly Asiatic in distribution, with the exception of a single species, the barbary ape (*Macaca sylvana*), of north Africa and the Rock of Gibraltar. The Asiatic range extends from western India to Japan and from northern China to the southernmost Indonesian islands. Macaques are robustly built with prominent muzzles recalling those of baboons but differing in the rounded profile, the nostrils being located on the upper surface. They are for the most part ill-tempered, though possessing a high degree of intelligence and learning capacity. They live in troops of varying size in much the same way as baboons; most species are somewhat more arboreal than baboons, however, but are equally at home on the ground or in rocky terrain. They are omnivorous feeders and breed all the year round, having a single young.

The numerous species differ greatly in the length of the tail. A few, e.g., the south Indian bonnet monkey (*Macaca radiata*) and its Ceylonese relative, the toque monkey (*M. sinica*), as well as the Malayan crab-eater (*M. irus*), are long-tailed. Most, like the rhesus (*M. mulatta*), have tails of moderate length. Several including *M. speciosa* of Thailand, are stump-tailed, while *M. sylvana* is completely tailless.

Remarkable for its educability is the pigtailed macaque (*M. nemestrina*), which is taught by the Malays to pick, at a command, only ripe coconuts. The Japanese macaque (*M. fuscata*) has long been a subject for local artists. See also PRIMATES: *Old World Monkeys* (*Catarrhines*): *Macaques*; **MONKEY**.

(W. C. O. H.)

MACARONI, a preparation of a glutinous wheat originally peculiar to Italy, where it is an article of food of national importance. The Italian form of the word is *maccheroni*. The same substance in different forms is also known as vermicelli.

AUTHENTICATED NEWS INTERNATIONAL

PANORAMIC VIEW OF MACAO

spaghetti, *tagliani*, *fanti*, etc.; general terms for these foods are alimentary pastes, *pasta* and Italian pastes. They are prepared from the hard, semitranslucent varieties of wheat which are cultivated in the south of Europe, Algeria and other warm regions and in the northwestern area of the American Great Plains, particularly northeastern North Dakota. They are distinguished by the Italians as *grano duro* or *grano da semolino*. Their preparations are more easily preserved than those of softer or more tender wheats of other regions. Common forms are fine thin threads (*vermicelli*), thin sticks and pipes (spaghetti, macaroni), small lozenges, stars, disks, ellipses, etc. (pastes). These different forms are prepared in a uniform manner from a granular product of hard wheat, which is distributed commercially under the name of *semolina* or *middlings*.

The *semolina* is thoroughly mixed with warm water and is kneaded into a stiff paste or dough in a kneading machine, such as is used in bakeries. Modern macaroni products manufacture is done by continuous mixing, kneading and extrusion rather than the batch procedures formerly used. The continuous press is equipped with feeders which furnish a constant flow of *semolina* and water at a rate of 200 to 1,500 lb. of *semolina* per hour. The continuous mixers push the product on while the dough is being mixed until at the end of the mixer the dough enters a tightly sealed auger. This moves the dough forward while compacting and further mixing it. The plastic dough is fed into a chamber or series of tubes behind a die. Vacuum often is employed during processing, which improves the colour of the finished product.

The pressure of 1,500 to 2,000 lb. per square inch built up in the dough forces it through the die, forming it into the desired shape. The soft, wet product is then dried from approximately 31% to 12% moisture content. For proper drying the air circulation, temperature and humidity must be strictly regulated; too rapid drying causes checking or cracking while slow drying may allow the product to stretch on the drying sticks or permit souring and mold growth. The drying rate is determined by the shape of the product; the drying air temperature, humidity and velocity; and the moisture content of the macaroni.

True macaroni can be distinguished by observing within the bend of the tubes the flattened mark of the rod over which it has been dried; it has a soft yellowish colour, is rough in texture, elastic and hard, and breaks with a smooth glassy fracture. In boiling it swells up to double its original size without becoming pasty or adhesive. It can be kept any length of time without alteration or deterioration.

(R. H. H.)

MACARONICS, burlesque Latin verses into which vernacular words are introduced with appropriate but absurd Latin endings. The inventor of the form was Teofilo Folengo (*q.v.*), a dissolute Benedictine who lived by his rhyming, and his *Baldus* (1517) is a burlesque epic of chivalry: ridiculous, squalid and satirical by turns. Its author described the macaronic as the literary equivalent of the Italian dish, in its 16th-century form a rustic mixture of flour, butter and cheese. The *Baldus* found many imitators in Italy and in France, and some macaronics were also written in mock-Greek. The outstanding British poem in this form is the *Polemio-Middinia inter Vitarvam et Nebernarn*, an account of a battle between two Fifeshire villages by the 17th-century Scottish poet William Drummond (*q.v.*), in which occur the lines:

Whistlavere viri, workhorsosque ordine swieros
Drivavere foras, donec iterumque iterumque
Fartavere omnes, et sic turba horrida mustat.

A derivative of the macaronic has been developed in England which pokes insular fun at the cumbrous grammatical complexities of the foreign tongues taught in school. Verses of this kind, though often composed by the teacher, are clearly intended for the learner. An early example is the *Polka Lyric* of Barclay Phillips, who invites his partner in two languages:

Polkam jungere, Virgo, vis,
Will you join the polka, miss?

Better known is A. D. Godley's declension of the *Motor Bus*, which concludes in the accusative plural:

Domine defende nos
Contra hos Motores Bos,

and F. Sidgwick's celebration of a coster bank holiday with its Virgilian opening in *Some Verse* published by Sidgwick and Jackson (1915):

Charmer virumque I sing, Jack plumigeramque Arabellam.

The German-American medleys of C. G. Leland (*q.v.*) in his *Hans Breitmann's Ballads* (1871) are also examples of the modern macaronic, in particular his warning *To a Friend Studying German*: "Will'st du learn die deutsche Sprache?" (Jo. M. C.)

MacARTHUR, ARTHUR (1845–1912), U.S. army officer, was born at Chicopee Falls, Mass., June 2, 1845. He served throughout the American Civil War in the 24th Wisconsin volunteer infantry, being advanced through the ranks from lieutenant to colonel of the regiment when but 20 years of age. His regiment gained fame in Gen. Philip Sheridan's division of the Army of the Cumberland where he was affectionately known as the "Boy Colonel of the West." He was wounded three times, brevetted four times, and cited for "gallant and meritorious service" in the battles of Perryville, Stones River, Missionary Ridge, Resaca, Dalton, Jonesboro, Kenesaw Mountain, Atlanta and Franklin. He was awarded the medal of honor for seizing the colours of his regiment at a critical moment and planting them on the captured works on the crest of Missionary Ridge. At the close of the war he entered the regular army and from 1866 to 1886 participated in Indian campaigns in the southwest. At the outbreak of the Spanish-American War (1898) he was appointed a brigadier general and assigned to the Philippine command. His brigade captured the town of Malate and thus prepared the way for the taking of Manila. He was cited by Gen. Wesley Merritt for gallantry and conspicuous service and appointed a major general to command the 2nd division. When the insurrection under Gen. Emilio Aguinaldo broke out in February of 1899 he commanded the main column which defeated the insurgents. He succeeded Gen. E. S. Otis in command of the 8th corps, the army of the Philippines, and as the military governor. In the latter capacity (1900–01) he helped to lay the foundations for a free and independent Philippine republic, introducing the writ of habeas corpus, revising the Spanish law and establishing the free public school system and other democratic concepts. During the Russo-Japanese War he was detailed as a special observer with the Japanese army. In 1906 he was appointed a lieutenant general and became the senior ranking officer of the U.S. army. He retired from the army in 1909 and died Sept. 5, 1912, at Milwaukee, Wis. (D. MacA.)

MacARTHUR, DOUGLAS (1880–1964), U.S. army officer who commanded Allied forces in the Pacific during World War II, served as supreme commander of occupation forces in Japan and of United Nations forces during the first nine months of the Korean War, was born on Jan. 26, 1880, at Little Rock barracks, Ark., the son of Arthur MacArthur (*q.v.*). In 1903 he graduated from the U.S. Military academy at West Point, first in his class and senior officer in the corps of cadets. He served with the military survey in the Philippines and on a study of colonial lands in the far east, including Korea (1905). He took part in the Veracruz (Mexico) expedition (1914), and in World War I rose to command the 42nd (Rainbow) division. After the war he was put in charge of the U.S. occupation sector along the Rhine. He served as superintendent of the U.S. Military academy (1919–22) and in 1925 was a member of the court-martial that tried aviation advocate Col. William ("Billy") Mitchell (*q.v.*). Although MacArthur is popularly believed to have voted for acquittal at this famous trial, the actual voting of the court members was, according to standard army procedure, not revealed. He served as department commander in the Philippines (1928–30) and as U.S. army chief of staff (1930–35). In preparation for Philippine independence, MacArthur, in 1935, was appointed military adviser to organize the islands' defenses. He was made a field marshal in the Philippine commonwealth army the following year, and continued to serve in the islands after his retirement from the U.S. army on Dec. 31, 1937.

World War II.—With tension mounting in the Pacific, MacArthur was recalled to active duty on July 26, 1941, to command U.S. and Philippine troops. When the Japanese attack came in

December, his outnumbered forces made a heroic stand on Luzon, falling back to the Bataan peninsula and the island of Corregidor where they were forced to capitulate during April and May 1942. For this gallant defense MacArthur was awarded the medal of honor, the same decoration his father had received more than 50 years before. Ordered by Pres. Franklin D. Roosevelt to leave the Philippines before the surrender, MacArthur arrived in Australia on March 17, 1942, after a daring 3,000-mi. dash through enemy-controlled seas. He opened his offensive campaign in the fall of 1942 with the invasion of New Guinea, and began to retake the areas conquered by Japan in the war's initial stages. Approaching the Philippines in 1944, he was ordered to bypass and neutralize them as he had many other Japanese strong points during the preceding two years. His arguments in favour of a Philippine invasion, however, persuaded President Roosevelt to allow him to retake the islands. Landings were made at Leyte in Oct. 1944, and by the following July the Philippines were again in Allied hands. Two months later, on Sept. 2, 1945, MacArthur, who had been appointed to the newly created rank of general of the army, accepted the Japanese surrender on board the U.S.S. "Missouri" in Tokyo bay. During the next five years, as supreme commander allied powers, he supervised the reconstruction of Japan and the establishment there of a democratic form of government.

Korean War.—When North Korean Communist troops crossed the 38th parallel and invaded South Korea in June 1950, MacArthur was put in charge of UN forces. Despite heavy odds against him, he was finally able to stop the Communist advance near the port of Pusan and, with the arrival of fresh UN units, plan his offensive, a surprise landing by amphibious troops at Inchon, far to the enemy rear. Subordinates and other high military officials at first opposed the plan but MacArthur was able to convince them of its feasibility and on Sept. 15, 1950, U.S. marine and army units landed at Inchon. At the same time UN forces to the south broke out of the Pusan perimeter and rolled north to effect a juncture with the amphibious forces. During the next two months the North Korean army was routed and all but destroyed. The intervention of the Chinese Communists late in November precipitated what MacArthur called a "new war" and UN forces were forced to withdraw south of the 38th parallel. By March 1951 MacArthur, having stopped the Chinese advance, was able to resume the offensive. Contrary to the policy of Pres. Harry S. Truman (*q.v.*), with whom he had conferred in Oct. 1950 at Wake Island, MacArthur urged the bombing of Communist bases in Manchuria, the blockade of the Chinese coast and the employment of Nationalist Chinese forces based on Formosa. This conflict of views led to his being relieved of his command on April 11, 1951.

Returning to the U.S., MacArthur addressed both houses of congress in a memorable speech, outlining, explaining and defending his policies in the far east. Thereafter, having been placed on the active list for life as general of the army, he retired to private life. The following year he delivered the keynote address at the Republican national convention, and in 1963 he wrote a volume of memoirs entitled *Reminiscences*. MacArthur died at Walter Reed army medical centre, Washington, D.C., on April 5, 1964, and was buried at Norfolk, Va.

See WORLD WAR II; KOREAN WAR; see also references under "MacArthur, Douglas" in the Index.

MACAULAY, THOMAS BABINGTON MACAULAY, BARON (1800–1859), English historian, essayist and politician, best known for his *History of England*, was born at Rothley Temple, Leicestershire, the seat of an uncle, on Oct. 25, 1800. His father, Zachary Macaulay, the son of a Hebridean minister, had been governor of Sierra Leone; an ardent philanthropist and ally of William Wilberforce the abolitionist, he was a man of severe Evangelical piety. His mother, a Quaker, was the daughter of a Bristol bookseller and an old pupil of Hannah More, who took a warm interest in her children. Before Thomas was eight years old he had written a *Compendium of Universal History* and a poem, *The Battle of Cheviot*, in the style of Sir Walter Scott; these were soon followed by other voluminous works. The boy was sent to a good private school, and in Oct. 1818, went up to Trinity

college, Cambridge, where he later became a fellow, and which held second place to his home in his affection throughout life. He gained in 1824 a college prize for an essay on the character of William III. He also won a Craven scholarship and wrote the English prize poems of 1819 and 1821, but failed to appear in the Tripos list through weakness in mathematics.

In 1826 Macaulay was called to the bar and joined the northern circuit. But he spent many more hours under the gallery of the house of commons than in the court. Meanwhile commercial disaster had fallen on the house of Babington and Macaulay, and the son saw himself faced with the necessity of earning money for his parents and their children as well as for himself, a burden which he accepted cheerfully and carried with complete success. He was never happier than when he was at home, and his deepest affection was reserved for two of his sisters, Margaret and Hannah. Meanwhile, in Aug. 1825, he had leapt to fame overnight with the first of his essays, that on Milton, published in the *Edinburgh Review*, which then, under the editorship of Francis Jeffrey, was the arbiter of literary fame and taste to the English-speaking world. It may seem surprising that social success should have been the consequence of a single article, but the writer was also a brilliant talker. At the university Macaulay had been pre-eminent for inexhaustible talk and genial companionship among a circle of such brilliant young men as Charles Austin, John Romilly, W. M. Praed and Charles Villiers. He now displayed these gifts on a larger stage. He was courted and admired by the most distinguished personages of the day. He was admitted at Holland house, where the formidable Lady Holland listened to him with deference and scolded him with a circumspection which was in itself a compliment. Samuel Rogers, the poet, spoke of him with friendliness and to him with affection.

Macaulay now began to aspire to a political career. His Trinity fellowship expired in 1831, and he could make at most £200 a year by writing, but he received a commissionership of bankruptcy from Lord Lyndhurst in 1828, and in Feb. 1830 he entered the house of commons for the "pocket borough" of Calne, offered him by Lord Lansdowne. Macaulay made his maiden speech on April 5, 1830, on the second reading of the bill for the removal of Jewish disabilities. On March 1, 1831, the Reform bill was introduced, and on the second night of the debate Macaulay made the first of his reform speeches, of which Sir Robert Peel said that "portions were as beautiful as anything I have ever heard or read." On the passing of the Reform act in June 1832, Macaulay, whose eloquence had signalized every stage of the conflict, became one of the commissioners and later secretary of the board of control, which represented the crown vis-à-vis the East India company. Giving his days to India and his nights to the house of commons, he could only devote a few hours to literary composition by rising at five in the morning. Between Sept. 1831 and Dec. 1833 he furnished the *Edinburgh Review* with eight important articles, besides writing his ballad *The Armada*.

In the first Reform parliament, Jan. 1833, Macaulay took his seat as one of the two members for the new borough of Leeds, and in July he defended the Government of India bill in a speech of great power. When the abolition of slavery came before the house as a practical question, Macaulay had the prospect of having to surrender office or of voting for a modified abolition proposed by the ministry, but condemned by the abolitionists. He placed his resignation in Lord Althorp's hands, and spoke against the ministerial proposal; the sense of the house compelled the ministry to give way, and Macaulay remained at the board of control. He then (1834) accepted a seat in the supreme council of India, created by the new India act. The salary of the office was fixed at £10,000, out of which he calculated to be able to save £30,000 in five years. His sister Margaret was now married; he took Hannah with him to India.

Macaulay's appointment to India occurred at the critical moment when the government of the company was being superseded by government by the crown. The part he took has been described as "the application of sound liberal principles to a government which till then had been jealous, close and repressive." He vindicated the liberty of the press; he maintained the equality of

Europeans and Indians before the law; and as president of the committee of public instruction he inaugurated the system of national education, and secured that this should be western in character. He was appointed also president of a commission to inquire into Indian jurisprudence, and the draft of a penal code which he submitted became in time the basis of the Indian criminal code. Meanwhile his life had been clouded with private sorrow. His sister Margaret died, and Hannah early in 1835 married a promising young servant of the company, Charles Trevelyan. The twofold blow was perhaps the severest suffering of his life.

In 1838 he returned to England and at once entered parliament as member for Edinburgh. In 1839 he became secretary for war, with a seat in the cabinet in Lord Melbourne's ministry. This diverted him for a time from prosecuting the plan he had already formed of a great historical work, but when in less than two years the Melbourne ministry fell, he published his *Lays of Ancient Rome* (1842) and in the next year a collection of his *Essays*. These he had never intended to reprint, but large unauthorized editions were selling in America. He returned to office in 1846, in Lord John Russell's administration, as paymaster general. In the sessions of 1846-47 he spoke only five times, and at the general election of 1847 he lost his seat for Edinburgh, where his cavalier treatment of regional interests and doctrinaire Whig principles had alienated public opinion.

He had in fact lost much of his interest in the political scene, and retired into private life with a sense of relief. Henceforward he abandoned general society for the intimacy of his own close relatives and one or two old friends of whom T. F. Ellis, his faithful correspondent, was chief, and for reunions with a group of sympathetic minds such as Samuel Rogers, Henry Hallam, Sydney Smith, Lord Carlisle, Lord Stanhope, Charles Grenville, Dean Milman and Sir Anthony Panizzi. He talked brilliantly, unceasingly and somewhat overbearingly. As his biographer G. O. Trevelyan remarks: "To get at his meaning people never had the need to think twice, and they certainly had seldom the time."

In these years he was working with unflagging industry upon his *History of England*, which was intended to run from the Revolution of 1688 to the death of George IV. His composition was slow, his corrections both of matter and of style endless; he spared no pains to ascertain the facts. He sacrificed to the prosecution of his task political career, house of commons fame, the allurements of society. The first two volumes appeared in Dec. 1848. The success was in every way complete beyond expectation. The sale of edition after edition, both in England and the United States, was enormous.

In 1852, when his party returned to office, he refused a seat in the cabinet, but the city of Edinburgh in contrite mood returned him unasked at the head of the poll at the general election that year. He had hardly accepted the summons to return to parliamentary life before his heart developed a fatal weakness; he wrote that he grew 20 years older in a day, and from this time forward his strength continued gradually to sink. His interventions in debate, though effective, were rare and costly.

In Nov. 1855 vol. iii and iv of the *History* appeared and attained a vast circulation. Within a generation of its first appearance more than 140,000 copies of the *History* were sold in the United Kingdom, and sales in the United States were on a correspondingly large scale. The work was translated into German, Polish, Danish, Swedish, Hungarian, Russian, Bohemian, Italian, French, Dutch and Spanish. He received many marks of respect from foreign academies, and his pecuniary profits were correspondingly large: the check received from his publisher, Longmans, for £20,000 has become a landmark in literary history. It may be safely said that no serious historical work on a comparable scale has ever been so widely diffused over the reading public both of the English-speaking world and of western Europe.

In May 1856 Macaulay quitted the Albany after 15 happy years and went to live at Holly Lodge, Campden Hill, surrounded by lawns and trees. In the following year he was raised to the peerage with the title of Baron Macaulay of Rothley. His health was now visibly failing every year; he never spoke in the house of lords, and gradually acquiesced in the conviction that he would

scarcely live to complete the reign of William III. He died on Dec. 28, 1859, and was buried in Westminster abbey.

Macaulay never married. His great capacity for affection found its satisfaction in the attachment and close sympathy of his sisters, and in particular of Hannah, later Lady Trevelyan, who remained in almost daily contact with him even after her marriage, and whose children were to him as his own. He was a steadfast friend, pure in morals throughout life, and no act inconsistent with the strictest honour and integrity was ever imputed to him. When a poor man, he twice resigned office rather than make compliances for which he would not have been severely blamed. He had a keen relish for the good things of life, and desired fortune as the means of obtaining them for himself and others; but there was nothing mercenary or selfish in his nature; it may be mentioned that in 1857 he wrote for the 8th edition of the *Encyclopædia Britannica* a series of five articles including those on Dr. Johnson and William Pitt, which have been judged the finest examples of his mature manner, for which he refused to accept any payment. When affluent, he gave away with an open hand, often rashly, and his last act was to dictate a letter to a poor curate and sign a check for £25.

The life of Macaulay was, as he repeatedly acknowledged, eminently happy. His exceptional gifts of mind were never, as they have been for so many men of genius, a source of calamity or mental anguish. Had he wished, he could have risen to high political place, perhaps to the highest; instead, he chose to live for literature and devoted his powers to the portrayal of the past of England. The feats of his memory, which was capacious and retentive to an extraordinary degree, have become proverbial. His command of literature was imperial. The literature and history of Greece and Rome were familiar from his college days to the end of his life, and few classical scholars had a wider sweep. To this he added the literature of his own country, of France, of Italy, of Spain and of Germany. He had his limitations. In later life he never gave expression to any religious conviction, and had no appreciation of spiritual, as distinct from ethical, excellence. All religious and philosophic speculation was alien to his mind, and he showed no interest in the marvellous discoveries of science which were succeeding each other day by day. A large part of ecclesiastical history lay outside his historical view. Of art he confessed himself ignorant, and to music he was completely deaf. At games, sports and physical skills—even that of tying a cravat—his incompetence was absolute.

His reputation, which during the last decade of his life was immense, fell steadily in the half-century that followed. His undisguised political partisanship, his superficial cast of mind, his easy and arrogant assumption that English bourgeois standards of comfort and progress were to be forever the norm for less favoured nations, the materialism, not to say vulgarity, of his judgments of value and taste, all came under heavy fire from Thomas Carlyle, Matthew Arnold and John Ruskin, while in the realm of historical studies a revolution, already accomplished in Germany during his lifetime but never appreciated by Macaulay, soon affected English historiography. The standards and interests of William Stubbs, of Lord Acton and of F. W. Maitland were very different from his. Wide as was Macaulay's reading, great as were the pains he took to acquire his information, his method and approach were entirely uncritical in the academic sense of that word, and he knew nothing of the austere and exigent standards of the best German and French work of his day. When he was describing the merits of friends and the faults of political enemies, even those of an earlier age, his pen knew no moderation. He had a constant tendency to glaring colours; he was not merely exuberant, but excessive; there was an overweening confidence about his tone; his propositions had no qualifications. Whereas the ordinary reader is reassured by this self-confidence, the more critical reader may be alienated by Macaulay's categorical affirmations about matters which our own experience of life teaches us to be of a more uncertain nature. We inevitably think of a saying attributed to Lord Melbourne: "I wish I were as cocksure of any one thing as Macaulay is of everything."

His mind was the mind of the advocate, not of the historian.

Yet his greatness remains. In the grasp and range of his knowledge, in his powers of vivid and sustained narrative and in the marshalling of his topics to serve a great design he is unsurpassed among English historians, except perhaps by Edward Gibbon. As for his style, which drove out the heavy classical periods, as well as the formless narrative, of the current history and journalism of his early years, it has become in its main features, such as its clarity, its tricks of emphasis and its use of the paragraph as the self-contained unit of expression, the characteristic English style for all purposes of exposition and persuasion, from the leading articles of higher journalism to the minutes of government departments. It is a forensic style, with no undertones or overtones of passion or poetry, and lacks the idiomatic flavour of a Dryden, as well as the sensitive, almost invisible matching of word with thought of a Newman, but for the purpose of effective exposition to be grasped by every reader it is unrivaled. His greatest gift is that of communicating to the reader, and especially to the young reader, his own vivid sense of the variety and human appeal of the past. Although his *Essays* were in origin no more than brilliant improvisations, and have proved vulnerable to criticism, they have done more than any other work to kindle enthusiasm for historical reading and in particular for English history of the 17th and 18th centuries. Macaulay had the rare gift of awakening in others his own intense mental delight in the spectacle of the past and the treasures of its literature. While his verse rarely, if ever, becomes poetry, and he had no ear for the purity of tone in Blake or Wordsworth, his glimpses of English landscape and wild life, both in the *History* and the ballads, reveal him as the contemporary of Thomas Bewick and John Sell Cotman.

The striking portrait by J. Partridge in the National Portrait gallery, London, shows him in the full vigour of manhood; his relatives considered the daguerreotype, reproduced in G. O. Trevelyan's *Life*, an excellent likeness from his later years. There is a statue in the ante-chapel of Trinity college, Cambridge.

BIBLIOGRAPHY.—The standard ed. of Macaulay's complete works is that in 12 vol. (1898). *The Life and Letters of Lord Macaulay*, 2 vol. (1876; enlarged ed. 1908, 1959 with full index), by his nephew, Sir George Otto Trevelyan, is acknowledged as one of the best biographies in the English language. Its excellence, and the absence of any complexity in Macaulay's life and character, have rendered it unnecessary and impossible to replace, and judgments on Macaulay's work, its excellences and faults, have likewise been singularly unanimous. His long correspondence with T. F. Ellis and his voluminous diaries, both used to good effect by Trevelyan, are in the possession of Trinity college, Cambridge, but they have no secrets to reveal, except that Macaulay could use a conversational idiom and make outspoken and summary judgments on his contemporaries. See also J. A. C. Morison, *Macaulay* (1882); Sir Arthur Bryant, *Macaulay* (1932); Sir C. H. Firth, *A Commentary on Macaulay's History of England* (1938). (M. P. A.; M. D. K.)

McAULEY, CATHERINE ELIZABETH (1787–1841), founder of the Sisters of Mercy, was born in County Dublin, Ire., Sept. 29, 1787. The McAuley children, orphaned at an early age, were entirely dependent on Protestant relatives, but Catherine could not be induced to join in Protestant worship. Left a small fortune, she invested it in a large building on Lower Baggot street, Dublin, and on Sept. 24, 1827, opened it as an institution for destitute women, orphans and the poor in need of schools.

At first there was no intention of forming a religious institute, but the work and way of life of Catherine McAuley's group soon led authorities to desire that they join the newly formed Irish Sisters of Charity. This situation was solved by the founding of a new congregation which was to combine the silence and prayer of the Carmelites with the active labours of the Sisters of Charity. The first novices were invested with the habit of the Sisters of Mercy on Dec. 12, 1831. At this same time Catherine McAuley was named superior, an office she held for the remainder of her life. She died in Dublin on Nov. 11, 1841. Her cause for beatification has been handicapped by the lack of authenticated miracles and primary documents. See also **MERCY, SISTERS OF**.

McAULIFFE, ANTHONY CLEMENT (1898–), U.S. army officer in the European theatre during World War II, was born in Washington, D.C., July 2, 1898. He graduated from the United States Military academy at West Point in 1919 and was commissioned in the field artillery. After routine service and school appointments during peacetime, McAuliffe served with airborne troops in World War II. He was acting commander of the 101st air-borne division in Dec. 1944 during the "battle of the bulge," and in this post his stout defense of Bastogne checked the German drive in the Ardennes and contributed to the ultimate German defeat. His terse reply to a German summons to surrender Bastogne—"Nuts!"—became a classic of World War II. During the postwar period, McAuliffe held various command and staff appointments, ending his military career as commanding general of the 7th army in Germany in 1953–55 and as U.S. army commander in Europe in 1955–56. He retired with the rank of general on May 31, 1956, to enter industry. (W. R. E.)

MACAW: see **PARROT**.

MACBETH, king of Scots from 1040 to 1057, the legend of whose life formed the basis of Shakespeare's *Macbeth*, was probably a grandson of Kenneth II and was married to Gruoch, a descendant (possibly the granddaughter) of Kenneth III. He was *morraer* (provincial ruler) of Moray, a position previously held by his father, and had probably attained the office by 1031. Macbeth established himself on the throne in 1040 when he killed Duncan I in battle near Elgin—not, as Shakespeare has it, by murdering him in bed. Both Duncan and Macbeth derived their right to the throne through their respective mothers and there was no rule of succession among Kenneth I's descendants that gave one a better claim than the other. The defeat of rebels, perhaps led by Crinan, father of Duncan, in a battle near Dunkeld in 1045 may account for the later story of Birnam wood. Earl Siward of Northumbria attempted, unsuccessfully, to dethrone Macbeth in 1046 in favour of Malcolm (afterward Malcolm III), the son of Duncan, but by 1050 Macbeth was secure enough to go on a pilgrimage to Rome. Nevertheless he was apparently forced by Siward to hand over part of southern Scotland to Malcolm in 1054 and was slain by Malcolm in battle at Lumphanan, in Mar, in 1057. Macbeth was buried at Iona, which was regarded as the resting place of kings but not of usurpers.

Macbeth's stepson, Lulach, who had established himself as king, perhaps in Moray, was slain in 1058. (A. A. M. D.)

McBRIDE, SIR RICHARD (1870–1917), Canadian politician, premier of British Columbia, 1903–15, established a record in that province for long tenure of office. Born at New Westminster, B.C., on Dec. 15, 1870, he was educated there and at Dalhousie university, Halifax, Nova Scotia. He entered the British Columbian legislature in 1898, became minister of mines in 1900, leader of the opposition in 1902 and premier in 1903, at the age of 32. He introduced the two-party system into the province's politics.

McBride's term of office coincided with the first great boom in the province. Population doubled; British, French and German capital poured into land, fisheries and mines; two transcontinental railways extended lines to British Columbia; and a network of railways was built within the province. His government founded the University of British Columbia and a provincial archives and library. In Aug. 1914, alarmed about the lack of security on the Pacific coast, he used provincial funds to purchase two submarines in Seattle, Wash.; later he turned them over to the Canadian navy.

Discouraged by the collapse of the real-estate boom and by failing health, he resigned in 1915 to become the province's agent-general in London. He died there on Aug. 6, 1917.

See Margaret A. Ormsby, *British Columbia: a History* (1958). (M. A. O.)

MACCABEES, the name (in the plural) of a distinguished Jewish family dominant in Jerusalem in the 2nd century B.C., effective in preventing the destruction of Judaism by Hellenism. According to I Macc. ii, 4, the name Maccabee, or Maccabaeus, was originally the distinctive surname of Judas, third son of the Jewish priest Mattathias, who struck the first blow for religious liberty during the persecution under Antiochus IV Epiphanes.

Subsequently, however, it obtained a wider significance, having been applied first to the kinsmen of Judas, then to his adherents, and ultimately to all champions of religion in the Greek period. It is now customary to apply it only to the sons and descendants of Mattathias. As, however, according to Josephus, this brave priest's great-great-grandfather was called Hasmon, the family is more correctly designated by the name of HASMONAEANS or ASMONAEANS. If Maccabee is the original form of the name, it is derived from a Hebrew word which is generally believed to be *maqabbi*, "the hammerer"; hence Judas Maccabaeus is "Judas the Hammerer," with reference to his beating down the enemies of the Jewish nation. But as Judas was surnamed "the Maccabee" before his military exploits, it is perhaps more probable that the name is derived, as A. Bevan suggested, from the verb *maqab*, "to designate," "to appoint"; hence "the one appointed [by Yahweh]."

The Maccabaean revolt was caused by the attempt of Antiochus IV Epiphanes, king of Syria, to force Hellenism upon Judaea (see ANTIOCHUS). In Dec. 168 sacrifice was offered to Zeus upon an idol altar erected over the great altar of burnt offering in the Temple. The issue of an edict ordaining the erection of heathen altars in every township of Palestine, and the appointment of officers to deal with recusants, brought matters to a crisis. At Modein, Mattathias, an aged priest, not only refused to offer the first sacrifice but slew an apostate Jew who was about to step into the breach. Having thus given the signal for rebellion, he then with his five sons took to the mountains. Many, including the *Hasidim* ("the pious"), who had constituted themselves champions of the Law, flocked to his standard, and set themselves to revive Jewish rites and to uproot paganism. In 166 Mattathias died, after nominating Judas as their leader.

The military genius of Judas made this the most stirring chapter in Israelite history. In quick succession he overthrew the Syrian generals Apollonius, Seron and Gorgias, and after the regent Lysias had shared the same fate at his hands he restored the Temple worship (165). These exploits dismayed his opponents and kindled the enthusiasm of his friends. When, however, Lysias returned in force to renew the contest, Judas had to fall back upon the Temple mount, and escaped defeat only because the Syrian leader was obliged to hasten back to Antioch in order to prevent a rival from seizing the regency. Under these circumstances Lysias unexpectedly guaranteed to the Jews their religious freedom (163). But though they had thus gained their end, the struggle did not cease. The *Hasidim* indeed were satisfied, and declined to fight longer, but the Maccabees determined not to desist until their nation was politically as well as religiously free.

In 161 Judas defeated Nicanor at Beth-horon, but within a few weeks thereafter, in a heroic struggle against superior numbers under Bacchides at Elasa, he was himself cut off. If in his brother Jonathan the cause which Judas had espoused did not possess so brilliant a soldier, it had in him an astute diplomatist who knew how to exploit the internal troubles of Syria. With all his cunning, Jonathan walked into a trap at Ptolemais, was made prisoner and ultimately slain (143). The leadership now devolved upon Simon, the last survivor of the sons of Mattathias, who succeeded in negotiating a treaty whereby the political independence of Judaea was at length secured in May 142. In the following year he was by popular decree invested with absolute powers, being appointed leader, high priest and ethnarch. As these offices were declared hereditary in his family, he became the founder of the Hasmonaean dynasty. The first year of his reign (143-142 B.C.) was made the beginning of a new era; issue of a Jewish coinage betokened the independence of his sovereignty. Under Simon's administration the country enjoyed prosperity, but in 135 he and two of his sons were murdered by Ptolemy, his son-in-law, who had an eye on the supreme power. Simon's third son, John Hyrcanus I, warned in time, asserted his rights as hereditary head of the state.

After the death of Antiochus VII Sidetes in 129 left him a free hand, John Hyrcanus (135-104) soon carved out for himself a large and prosperous kingdom, which, however, was rent by internal discord owing to the antagonism developed between the rival parties of the Pharisees and Sadducees. Hyrcanus was succeeded by his son Aristobulus, whose reign of but one year was followed

by that of his brother, the warlike Alexander Jannaeus (103-76). The new king's Sadducean proclivities rendered him odious to the populace, which rose in revolt, but only to bring upon itself a savage revenge. The accession of his widow, Salome Alexandra (76-67), witnessed a complete reversal of the policy pursued by Jannaeus, for she chose to rule in accordance with the ideals of the Pharisees. (For the differing views of Sadducees and Pharisees, see JEWISH SECTS DURING THE SECOND COMMONWEALTH.) Her elder son, John Hyrcanus II, a pliable weakling, was appointed high priest; her younger son, the energetic Aristobulus, who chafed at his exclusion from office, seized 20 strongholds and with an army bore down on Jerusalem. At this crisis Alexandra died, and Hyrcanus had to retire in favour of his brother (see also HYRCANUS).

A new and disturbing element now entered into Jewish politics in the person of the Idumaean Antipater, who for selfish ends deliberately made mischief between the brothers. An appeal to M. Aemilius Scaurus, who in 65 came into Syria as the legate of Pompey, led to the interference of the Romans, the siege of Jerusalem by Pompey and the vassalage of the Jews. Repeated but fruitless attempts were made by the Hasmonaeans and their patriotic supporters to throw off the Roman yoke. At length, in 40, the Parthians set up as king Antigonus, sole surviving son of Aristobulus. Through the execution of Antigonus by Mark Antony in 37 B.C. the Hasmonaean dynasty became extinct. (See also JEWS: Greek and Roman Conquests; PALESTINE: Prehistory and History; SELEUCID DYNASTY.)

Another set of brothers, also called Maccabees (though not so named in II Macc. vii, where their story is given), who were executed because they refused to break the commands of the Jewish Law, were regarded as examples of martyrdom in the early Christian period and are celebrated as saints on Aug. 1 in both the eastern and western churches. See also MACCABEES, BOOKS OF.

BIBLIOGRAPHY.—I and II Macc. and Josephus are the main sources for the Maccabaean history. See also Madden, *Coins of the Jews* (1881); E. Beurlier in F. Vigouroux (ed.), *Dictionnaire de la Bible*, vol. iv, cols. 479-488 (1908); C. C. Torrey in T. K. Cheyne and J. S. Black (eds.), *Encyclopaedia Biblica*, vol. iii, cols. 2850-58 (1902); H. Weiss, *Judas Makkabäus* (1897); A. W. Streane, *The Age of the Maccabees* (1898); E. Schürer, *Geschichte des jüdischen Volkes im Zeitalter Jesu Christi*, 4th ed., vol. i (1901); E. Bickermann, *The Maccabees*, trans. by M. Hadas (1947), *Der Gott der Makkabäer* (1937). (W. F.; X.)

MACCABEES, BOOKS OF. All four books of Maccabees, none of which is in the Hebrew Bible, appear in some manuscripts of the Septuagint; the first two only are part of canonical Scripture in the Septuagint and the Vulgate (hence are canonical to Roman Catholicism and Eastern Orthodoxy) and are included in the Protestant Apocrypha (see APOCRYPHA, OLD TESTAMENT).

I Maccabees.—The first Book of Maccabees, of which the Hebrew original (seen by Jerome) is lost, is a history of the Maccabees (q.v.) from the attempts of Antiochus IV Epiphanes of Syria to root out the Jewish religion until the death of Simon Maccabaeus (175-135 B.C.). The first chapter sets the scene, with an account of the natural pressure on the Jews since the time of Alexander the Great to conform to the customs of their Hellenistic neighbours and the active measures of Antiochus in forbidding Jewish practices and defiling the Temple. (See JEWS.) The book then describes the revolt of the priest Mattathias, who refused to obey Antiochus' commands and together with his five sons and other followers fought for the defense and reinstatement of Judaism (ch. ii). On his death his son Judas Maccabaeus took over the command of the Jewish forces and won a series of victories, after which the Temple was purified and reconsecrated at a dedication festival lasting eight days (ch. iii-iv). There was further fighting; but before Judas was finally killed in battle he had made a treaty with the Romans (v-ix, 22). His brother Jonathan, who succeeded to the command, was finally recognized as the Jewish ruler, being made high priest (ix, 23-xii). After Jonathan was killed by the Syrians at Ptolemais his brother Simon succeeded in ejecting the Syrian garrison from Jerusalem and inaugurated a period of prosperity; he was made ruler and high priest, but was murdered after a short reign (xiii-xvi).

The first Book of Maccabees was perhaps written toward the end

of the 2nd century B.C., after the death of Simon's son, John Hyrcanus, who is referred to in the last two verses. The author, a reliable historian whose theme is that Hellenism is the root of all evil, was a Palestinian Jew utterly devoted to the national cause and quite possibly a Sadducee, for he is not against the profanation of the sabbath. The work is characterized by a religious reticence which never refers directly to God or mentions the messianic hope.

II Maccabees.—The second Book of Maccabees, which was probably written originally in Greek, is the work of a preacher rather than of a historian. In the prefatory letters (ch. i-ii) addressed to the Jews of Alexandria by the Jews of Jerusalem it claims to be the epitome in one book of a lost five-volume history by Jason of Cyrene covering the period 176-161 B.C. The book then tells of the heavenly apparition sent by God to preserve the Temple from desecration (ch. iii) and of various other attempts to Hellenize the Jews, including the martyrdom of the priest Eleazar and the seven brothers who refused to break the law by eating forbidden food (ch. iv-vii). The climax comes with the victories of Judas Maccabaeus, the subsequent purification and rededication of the Temple and the independence of Jerusalem from foreign control (ch. viii-xiii). The aim of the book is to uphold the Jewish faith by stressing God's mighty power shown clearly in heavenly apparitions (v, 1-4; x, 29-31; xi, 8; etc.), by relating examples of steadfastness in obeying the Law (e.g., sabbath observance, vi, 11; viii, 25 ff.; xii, 38; xv, 1) and by urging the celebration of national festivals (i, 9; x, 5 ff.; xv, 36). The book, which probably dates from the 1st century B.C., refers to the resurrection of the dead and to prayers for the dead, which it says would be pointless if there were no resurrection (xii, 43-45). The prophet Jeremiah is also said to pray for the Jewish people and for the holy city (xv, 14).

III Maccabees.—The third Book of Maccabees, which is without historical foundation, tells the story of a persecution against the Jews said to have been attempted by Ptolemy IV Philopator (221-204). Incensed at being miraculously prevented from entering the Temple in Jerusalem, Ptolemy commanded that the Jews of Alexandria should be trampled underfoot by 500 drunk elephants, but a further miracle diverted this fate from the Jews to the Egyptians. The purpose of the writer was evidently to encourage the Jews of Alexandria during persecution, but there is no clear allusion to dates. The book must, however, have been written after the Maccabean period and before the fall of Jerusalem in A.D. 70. A somewhat similar event is related by the Jewish historian Josephus as taking place in the reign of Ptolemy VII Euergetes II (170-164 and 145-117). Greek was the original language of III Maccabees, which probably owes its title to being placed after I-II Maccabees in manuscripts. The book is also found in the Syriac Peshitta and in an Armenian translation.

IV Maccabees.—The fourth Book of Maccabees is a philosophical discourse on the supremacy of religious reason over the passions. It shows how the four cardinal virtues can be practised by obeying the Jewish Law. Its title is probably due to the fact that it is largely devoted to retelling the story, also related in II Maccabees, of how the priest Eleazar and the seven brothers were martyred for their determination to obey the Law. It has been suggested that the book was composed for delivery at an annual commemoration of these Maccabean martyrs, possibly in Antioch where later tradition located their tomb. This suggestion is supported by the fact that the book was later so used by the church; it is found in many manuscripts of Greek service books as an appropriate homily for Aug. 1, the day when the Maccabees are remembered in the Christian calendar. In some manuscripts and in certain editions the book appears among the works of Josephus, to whom it is also attributed by various Church Fathers, but it differs greatly in outlook, method and vocabulary from Josephus' authentic writings. The author of the book, who wrote in Greek, was an unknown Hellenistic Jew who had studied Greek philosophy and probably lived in the 1st century B.C. There is a Syriac version of the book in the Peshitta and a Latin paraphrase entitled *Passio SS. Machabaeorum*. The book was popular among Christian preachers (e.g., Gregory of Nazianzus and John Chrysostom)

as providing a superlative example of steadfastness, for the Maccabees could have no faith in Christ to sustain them in their martyrdom. See also BIBLE.

McCARTHY, JOSEPH RAYMOND (1908-1957), U.S. senator who gained prominence with anti-Communist charges during the 1950s, was born on a Grand Chute farm near Appleton, Wis., on Nov. 14, 1908. He worked his way through Marquette university, Milwaukee, Wis., and received a law degree in 1935. He then began to practise law and entered politics, first as a Democrat and then as a Republican. Elected circuit judge in 1939, he left the bench three years later to enlist in the U.S. marine corps where he served during World War II as an enlisted man and as an officer. After returning home he won a striking victory over Sen. Robert M. La Follette, Jr., in the Wisconsin Republican primary election in 1946, and defeated the Democratic candidate in the fall. He made his home in Appleton and was re-elected to the senate in 1952.

Senator McCarthy became nationally prominent after he took up the Communist issue in 1950. Working alone and through senate committees, he charged that Communists and fellow travelers had infiltrated the U.S. department of state and other government offices. He drove some persons out of their jobs and brought popular condemnation on others. His accusations, always colourful and cleverly presented, won him widespread support as a crusader against Communism. Many Americans and Europeans, however, denounced McCarthy as a demagogue whose reckless charges did disservice to the anti-Communist cause. To them, "McCarthyism" meant accusation without proof.

During Pres. Dwight D. Eisenhower's administration McCarthy broke with leaders in his own party. Though he had built his strength on congressional investigations, he lost influence in 1954 as a result of the sensational, nationally televised hearing on McCarthy's charges against army officers and civilian officials. When the Republicans lost control of the senate as a result of the autumn elections of 1954 McCarthy lost his chairmanship of the investigating committee and soon thereafter, on Dec. 2, 1954, was formally condemned by the senate, 67-22, for conduct "contrary to Senate traditions." He had not regained his former power when he died at Bethesda, Md., on May 2, 1957.

See William F. Buckley, Jr., and L. Brent Bozell, *McCarthy and His Enemies* (1954) for a favourable estimate; see Richard H. Rovere, *Senator Joe McCarthy* (1959) for a critical view. (F. H. Hn.)

MC CARTHY, JUSTIN (1830-1912), Irish politician, historian and novelist, best known for his *History of Our Own Times* and his *Reminiscences* (1899), was born in Cork on Nov. 22, 1830, and educated there. He entered journalism as a reporter on the *Cork Examiner* and in 1854 joined the *Northern Daily Times* in Liverpool. He subsequently became foreign editor of the *Morning Star* and its editor till 1868. Having made his name as a novelist with such successes as *Dear Lady Disdain* (1875) and *Miss Mischance* (1878), he published his *History of Our Own Times* (1879-97), which won general recognition. In 1879 he entered Irish politics as member for County Longford, and became vice-chairman of the new Home Rule party under Charles Stewart Parnell (q.v.). In 1886 he won Londonderry city for Parnell; but when conflict arose over Parnell's leadership, McCarthy became chairman of the anti-Parnellites. At the general election of 1892 his party won an overwhelming majority, but McCarthy had no political ambitions and in 1896 resigned in favour of John Dillon. His health soon broke down with almost total blindness, but he continued writing by dictation. He died at Folkestone, Eng., on April 24, 1912. (D. G.)

McCLELLAN, GEORGE BRINTON (1826-1885), the most controversial Union general of the American Civil War, was

born in Philadelphia, Pa., on Dec. 3, 1826. He was educated at the University of Pennsylvania preparatory school and at the age of 15, with special permission, was admitted to the United States Military academy at West Point, graduating second in his class in 1846. The newly commissioned officer was detailed as a military engineer with Gen. Winfield Scott's expedition in the Mexican War and was breveted twice for distinguished conduct under fire. From 1848 to 1851 he was an instructor at West Point.

McClellan was directed to explore the Red river in Arkansas in 1852 and the following year he was in command of an expedition to survey a route for a railway across the Cascade mountains. In 1854 he was sent on a secret mission to Santo Domingo to examine facilities for a possible U.S. naval base there. The war department then ordered him to the Crimea where he observed European methods of conducting warfare and gained valuable experience. At this time he also designed a new type of saddle, afterward known as the McClellan saddle, for the cavalry.

McClellan resigned his captain's commission in 1857 to become chief engineer with the Illinois Central railroad, and in 1860 he was appointed president of the Ohio and Mississippi railroad with offices in Cincinnati. On May 22, 1860, he married Ellen Mary Marcy, who was to bear him a son and a daughter.

Although a states' rights Democrat, McClellan was a staunch Unionist, and in April 1861, at the outbreak of the Civil War, he accepted appointment as major general of the Ohio volunteers. The following month he was commissioned in the regular army and was placed in command of the department of the Ohio; he assumed responsibility for holding western Virginia for the Union. By July 13 the Confederate forces in this area had been defeated, and McClellan had established a reputation as the "Young Napoleon of the West" because of his issuance of bombastic manifestoes to soldiers under his command.

After the Union reverse at Bull Run in July 1861, McClellan was called to Washington and placed in command of the department (later army) of the Potomac; he was charged with the defense of the capital and with the destruction of the enemy's forces in northern and eastern Virginia. Upon the retirement of the aged General Scott as general-in-chief of the army in Nov. 1861, McClellan assumed this office, a position he was to hold only until March 1862.

McClellan's organizing abilities and logistical understanding brought order out of the chaos of defeat and he was brilliantly successful in whipping his army into a fighting unit with high morale, an efficient staff and effective supporting services. Yet he refused to take the offensive against the enemy in the fall of 1861, claiming that the army was not prepared to move. President Lincoln, disturbed with McClellan's inactivity, issued his famed General War Order No. 1 calling for the forward movement of all armies on Feb. 22, 1862, as a means of prodding his numerous reluctant generals. "Little Mac" was able to convince the president that a postponement of two months was desirable. He also succeeded in persuading Lincoln that the army of the Potomac should take the offensive against the enemy capital at Richmond from the peninsula between the York and James rivers rather than by the overland north-south route.

The Peninsula campaign continued in May 1862 after a one-month siege of Yorktown, and although McClellan was never really defeated by the enemy and actually won several victories, notably at Malvern hill, he was cautious and always failed to press his advantage. Coming to within a few miles of Richmond, he consistently miscalculated the number of enemy troops opposing him. Disappointed with Lincoln's action in withholding McDowell's corps from his control for the protection of Washington, McClellan was forced to make a strategic withdrawal to the James river because his army was now divided by the Chickahominy river. Although the Confederate forces under Gen. Robert E. Lee began an all-out attempt to destroy McClellan's army in the Seven Days' battle (June 26 to July 2), the Union troops retreated successfully to a new base of operations at Harrison's Landing. Lincoln's discouragement over McClellan's failure to take Richmond or to defeat the enemy decisively led to the withdrawal of the army from the Potomac from the peninsula.

McClellan returned to Washington just as the news of the demoralizing setback for Federal troops at Second Bull Run (Aug. 29-30, 1862) was received, and he was requested to take command of the army for the defense of the capital. Again exercising his organizing capacity, he was able to rejuvenate the Union forces. When Lee moved north into Maryland, McClellan's army met the Confederates at the battle of Antietam (Sept. 17, 1862), where a Union victory prevented any extension of the invasion. McClellan once again failed to move rapidly to destroy Lee's army, and the exasperated Lincoln removed him from his command in Nov. 1862.

In 1864 McClellan was nominated for the presidency by the Democratic party on a platform that denounced the war as a failure; he repudiated this position but accepted the nomination. On election day McClellan resigned his commission in the army and later sailed for Europe. He returned in 1868, and after declining the presidencies of the new University of California and Union college, he became chief engineer of the department of docks in New York city from 1870 to 1873. In 1871 he also served as one of three trustees to reorganize the Atlantic and Great Western railroad and became its president in 1872. Elected governor of New Jersey on the Democratic ticket in 1877, McClellan served one term and spent the remaining years of his life in traveling and writing his memoirs. He died suddenly on Oct. 29, 1885, at Mayfield, Orange, N.J.

As a general, McClellan was a superior organizer, had an excellent grasp of military strategy, and was well liked by the men who served under him, but he was overly cautious and insufferably egocentric in his dealings with civilian superiors. Most important, he lacked the ability to view the Civil War as more than the clash of opposing armed forces.

McCLERNAND, JOHN ALEXANDER (1812-1900), U.S. politician and Civil War general, was born near Hardsburg, Ky., May 30, 1812. The family soon moved to Illinois, and in 1832 McClernand was admitted to the bar in Shawneetown, Ill. He served in the Black Hawk War, was active in militia affairs and later edited a local newspaper. He served as a Democrat in the U.S. house of representatives from 1843 to 1851 and again from 1859 to 1861. Upon the outbreak of the Civil War he resigned from congress and returned to Illinois to raise troops.

McClernand was commissioned brigadier general of volunteers on May 17, 1861. At Belmont, at Ft. Henry and Ft. Donelson, and at Shiloh he was one of the senior commanders and was promoted to major general on March 21, 1862. Thereafter his tactless behaviour made for increasing conflict and misunderstanding with Ulysses S. Grant. Following his unauthorized capture of Arkansas Post on Jan. 11, 1863, General Grant recalled him, and throughout the rest of the Vicksburg campaign the schism between the two officers widened. Grant accused McClernand of tardiness at Champion Hill and Grand Gulf, and blamed him for unwarranted casualties. McClernand meanwhile issued a congratulatory order virtually claiming victory for his own division. This order angered Grant, who relieved him in June 1863, but Pres. Abraham Lincoln, unwilling to anger the War Democrats, reinstated him in Feb. 1864. Lack of military success and ill health caused McClernand to resign Nov. 30, 1864. He continued to be a power in the Democratic party in Illinois after the war, holding elective and appointive offices. He died at Springfield, Ill., Sept. 20, 1900.

MACCLESFIELD, EARLS OF. The earldom of Macclesfield was created in 1679 for CHARLES GERARD (c. 1618-94) who had supported Charles I in the Civil War, commanding a brigade at Edgehill and distinguishing himself at Newbury (1643) and Newark (1644). He was given the command in south Wales where his severity made him unpopular, and was also lieutenant general of the King's horse. Created Lord Gerard of Brandon in 1645, he retired to the continent in 1646 after Oxford had fallen

to the parliamentarians. Gerard returned in 1660 with Charles II; his estates were restored and he received a pension. He was created earl of Macclesfield and Viscount Brandon in 1679, but his sympathies with the duke of Monmouth led to his temporary arrest in 1685. Macclesfield escaped abroad, to return with William III in 1688 as commander of his bodyguard. He was made privy councillor and president of the council in the Welsh marches in 1689. Macclesfield died on Jan. 7, 1694. CHARLES (c. 1659–1701), 2nd earl, was also involved in Monmouth's intrigues. He was sentenced to death in 1685 for complicity in the Rye House plot, but was later pardoned. He divorced his first wife, Anne, by act of parliament, thus creating legal precedent since no previous decree had been obtained in an ecclesiastical court. The poet, Richard Savage, claimed to be the younger of two illegitimate children of Anne by Richard Savage, Earl Rivers. Charles was succeeded, briefly, by his brother, FITTON (c. 1665–1702), 3rd earl, on whose death the title became extinct.

The title was revived in 1721 for THOMAS PARKER (1667–1732), a lawyer who took part in the proceedings against Dr. Henry Sacheverell. He was appointed lord chief justice in 1710 and lord chancellor in 1718. Impeached for corruption in 1725 he was found guilty and fined heavily. GEORGE (1697–1764), 2nd earl of this creation, was a celebrated astronomer who was prominent in introducing the new style of dates in 1752. He was president of the Royal society and died on March 17, 1764. GEORGE (1755–1842), 4th earl, was president of the board of agriculture from 1816 to 1818. GEORGE (1888–), 7th earl, succeeded to the title in 1896.

MACCLESFIELD, a municipal borough and market and manufacturing town in the Macclesfield parliamentary division of Cheshire, Eng., 18 mi. S.S.E. of Manchester by road. Pop. (1961) 37,644. It stands on the Bollin river in a deep gorge with heights up to 1,600 ft. on the east where the bleak upland country retains its ancient name of Macclesfield forest. Steps and terraces connect the low lying Waters Green near the river, where the Barnaby and May fairs are held, with the upper part of the town with its many steep, cobbled streets. The church and town hall crown the hill where gardens are now laid out. St. Michael's church was founded in 1278 by Queen Eleanor and was once connected with the two private chapels of the Savage and Legh families. The Savage chapel belonged to a college of secular priests founded in 1508 by Thomas Savage. A Unitarian chapel, built in 1689, stands behind a fine wrought iron gate. The King's school was founded in 1502 as a free grammar school and refounded in 1552. There are also a technical school and a school of art. The museum was built in 1898. The most important industry is silk manufacture; cork, paper, shirts, shoes and electrical appliances are also produced. Stone is quarried locally.

Before 1066 Macclesfield was held by Edwin, earl of Mercia; the Domesday Book records it in the lands of the earl of Chester where it remained until 1244 when it lapsed to the crown. The forest remained a royal forest until after the Restoration, but by the 18th century it had been enclosed and cultivated. In 1389 John de Macclesfield obtained permission to fortify his mansion; it was later owned by the duke of Buckingham and then by the earl of Derby; it was destroyed in the Civil War when the town walls also were demolished. The names Jordangate, Chestergate and Wallgate bear witness to the ancient fortifications. The earliest of many charters was granted by Ranulf (or Randolph), earl of Chester, in 1220; in 1261 another, granted by Edward (later Edward I), constituted Macclesfield a free borough with a merchant guild. In 1684 Charles II issued the last charter which continued until 1835. The markets, first mentioned in 1617, are still flourishing. The charter of Elizabeth I (1564) granted an annual fair in June, and Charles II granted fairs in April and September. The present fairs are held in May and October. Macclesfield first sent two members to parliament in 1832; in 1880 it was disfranchised and in 1885 it was merged in the county division of Macclesfield.

The manufacture of silk-covered buttons began in the 16th century and flourished until the early 18th. Charles Roe, who came to Macclesfield in 1740, introduced silk throwing in 1756, when the first silk mill was erected, and fostered the silk and metal-

working industries. By 1790 silk manufacture was being carried on on a large scale and in 1831 the Macclesfield canal, between the Trent and Mersey canal and the Peak Forest canal, was opened. In 1845 the railway connected Macclesfield with Stockport.

McCLINTOCK, SIR FRANCIS LEOPOLD (1819–1907), British naval officer and arctic explorer, who made known the fate of Sir John Franklin's expedition, was born at Dundalk, Ire., on July 8, 1819. He went to sea at the age of 12 and served in several ships of the Royal Navy before joining the Franklin search expedition of 1848–49 under Sir James Clark Ross, as second lieutenant of the "Enterprise." During his second arctic season (1850–51) as first lieutenant of the "Assistance," and during his third (1852–54) when he commanded the "Intrepid," he improved on Ross's sledging methods and equipment, and initiated a system of depot laying which resulted in some great man hauling journeys. McClintock's party in the spring of 1853 traveled 1,328 mi. in 105 days, and sledge journeys of comparable length were made in 1854, and during his last searching expedition of 1857–59. Much new coast line was explored, but no traces found of Sir John Franklin (q.v.). After many fruitless expeditions, news of the fate of the lost party was obtained in 1854 by John Rae from the Eskimo of Boothia peninsula. The government refused to equip another expedition, so Lady Franklin sent McClintock in the "Fox" to King William Island, off which Franklin's ships, the "Erebus" and "Terror," had been beset. Through him the fate of the expedition was made known and many relics discovered, including a record left on the island. These relics and McClintock's own papers are in the National Maritime museum. He died on Nov. 17, 1907.

McCLINTOCK, JOHN (1814–1870), U.S. Methodist Episcopal theologian and educator, an able preacher, orator and teacher, and a versatile scholar, was born in Philadelphia, Pa., on Oct. 27, 1814. After his graduation from the University of Pennsylvania in 1835 he taught in Dickinson college for 12 years. He edited the *Methodist Quarterly Review* (1848–56), and in 1867 at the wish of Daniel Drew, became president of the newly established Drew Theological seminary at Madison, N.J., where he died on March 4, 1870.

McClintock by his editorial and educational work probably did more than any other man to raise the intellectual level of American Methodism. He put into practice the scholarly methods of the new German theology of the day, not alone by his translation with Charles E. Blumenthal of Neander's *Life of Christ* (1847) and of Bungener's *History of the Council of Trent* (1855) but by his own noteworthy project, McClintock and Strong's *Cyclopaedia of Biblical Theological and Ecclesiastical Literature* (1867–81; supplement, 1885–87). Among McClintock's other publications are *Sketches of Eminent Methodist Ministers* (1853), *Living Words* (1871) and *Lectures on Theological Encyclopaedia and Methodology* (1873).

See G. R. Crooks, *Life and Letters of the Rev. Dr. John McClintock* (1876).

McCLOSKEY, JOHN (1810–1885), U.S. Roman Catholic archbishop of New York, the first U.S. cardinal, was born in Brooklyn, N.Y., March 10, 1810. Educated at Mount St. Mary's college, Emmitsburg, Md., he was ordained a priest in 1834, spent two years in graduate study at the Gregorian university in Rome and returned to New York city in 1837 as rector of St. Joseph's church. In 1841 he organized and became first president of St. John's college (later Fordham university). After serving from 1844 to 1847 as bishop coadjutor to Bishop John Hughes of New York, he became first ordinary of the newly created see of Albany, N.Y. Succeeding to the archbishopric of New York in 1864, he renewed construction of St. Patrick's cathedral, suspended during the Civil War, and dedicated the edifice on May 25, 1879. Elevated to the cardinalate in 1875, he journeyed to Rome in 1880 but arrived too late to attend the conclave that elected Pope Leo XIII. He died in New York on Oct. 10, 1885.

See J. M. Farley, *The Life of John Cardinal McCloskey* (1918).
(J. A. Rs.)

McCLURE, SIR ROBERT JOHN LE MESURIER (1807-1873), British arctic explorer who commanded the first expedition to complete the Northwest passage, though Sir John Franklin was later credited with its discovery, was born at Wexford, Ire., on Jan. 28, 1807. He joined Sir George Back's arctic expedition of 1836-37, and the Franklin search expedition of 1848-49 under Sir James Clark Ross. In 1850, McClure, commanding H.M.S. "Investigator," accompanied Sir R. Collinson, in H.M.S. "Enterprise," to search again for Franklin's lost expedition. "Investigator" preceded "Enterprise" through Bering strait and discovered a northwest passage, finding one route through Prince of Wales strait and another round Banks Island. Having abandoned ship off Banks Island, the expedition joined the "Resolute" and "Intrepid" of the search expedition commanded by Horatio Austin, at Melville Island. These ships were in turn abandoned, and McClure's party went on foot to Beechey Island and thence home by ship in 1854. (See also ARCTIC, THE.) McClure died in London on Oct. 17, 1873.

BIBLIOGRAPHY.—George Back, *Narrative . . .* (1838); Sherard Osborn, *The Discovery of a Northwest Passage* (1856); Alexander Armstrong, *A Personal Narrative of the Discovery of the North-West Passage* (1857); R. McClure, *Voyages . . .*, 2 vol. (1884). (A. M. Ss.)

MCCONNELL, FRANCIS JOHN (1871-1953), U.S. Methodist bishop, was born at Trinway, Ohio, Aug. 18, 1871. He graduated at Ohio Wesleyan university and later studied at Boston university. In 1894 he entered the Methodist ministry and was pastor successively at Chelmsford, Newton, Ipswich and Cambridge, all in Massachusetts, and in 1903-09 at the New York Avenue Methodist church in Brooklyn. From 1909 to 1912 he was president of De Pauw university. He was elected bishop in 1912 and served for a number of years in Mexico and afterward in the Pittsburgh, Pa., district. In the latter region he entered actively into a study of industrial conditions and problems. As chairman of the Commission of Inquiry appointed by the Interchurch World Movement organization he pushed the investigation resulting in the *Report on the Steel Strike of 1919* which was influential in abolishing the 12-hour day and seven-day week in the steel industry. He wrote many books, among which are: *Personal Christianity* (1914); *Christianity and Coercion* (1933); *John Wesley* (1939); and *Evangelicals, Revolutionists and Idealists* (1942). Bishop McConnell retired in 1944 and died at Lucasville, Ohio, on Aug. 18, 1953.

MCCOOK, ALEXANDER McDOWELL (1831-1903), U.S. army officer, was born in Columbiana county, O., April 22, 1831, and graduated from the United States Military academy at West Point in 1852. He did garrison duty in the west and served as an instructor at West Point prior to the American Civil War, in which he and seven of his brothers, known as the "fighting McCooks," served. In April 1861 he became a colonel of Ohio volunteers, fought in the first battle of Bull Run and commanded a brigade in Kentucky. He next led a division in the army of the Ohio, fighting at Corinth, Nashville and Shiloh. He fought with the army of the Cumberland at Chickamauga, was blamed for the Union defeat and relieved of his command. A board of inquiry exonerated him and he returned to duty. At the end of the war, having risen to the rank of major general of volunteers, he resumed his rank of lieutenant colonel in the regular army, serving in several infantry regiments. He was aide-de-camp to Gen. William T. Sherman from 1875 to 1880. He became a brigadier general in 1890 and a major general in 1894, and retired the next year. He later served on the commission which investigated the conduct of the war department in the Spanish-American War. He died in Dayton, O., on June 12, 1903. (C. W. Tr.)

MCCORMACK, JOHN (1884-1945), Irish-U.S. operatic and concert tenor, was born at Athlone, Ireland, on June 14, 1884. He won the prize at the *Feis Ceoil* in Dublin in 1902 and later studied in Italy under Sabatini. He made his operatic debut at Covent Garden in *Cavalleria Rusticana* in 1907 and appeared at the Manhattan opera house, New York, in *Traviata* in 1909. He afterward sang with the Chicago and Boston opera companies and

the Metropolitan opera company. In 1911 he toured Australia with Melba in Italian opera. After two further operatic seasons, he turned to the concert stage, where he achieved an extraordinary popularity confirmed in many fine phonograph records. He became a U.S. citizen in 1919 and was made a count in the papal peerage in 1928. McCormack died Sept. 16, 1945, near Dublin.

See L. A. G. Strong, *John McCormack* (1949).

MCCORMICK, CYRUS HALL (1809-1884), U.S. inventor of the reaper, was born in Rockbridge county, Va., on Feb. 15, 1809. He was the eldest son of Robert McCormick, an inventor of farm machinery and a major factor in the early development of the reaper. In 1831 Cyrus demonstrated a successful reaper, the principles of which have been essential to all subsequent grain-cutting machines. He obtained a patent on his invention in 1834 and in 1847 established his factory in Chicago. McCormick expanded the business and defended its patent rights, charging his brothers, Leander J. and William S., with management of the concern. In 1858 Cyrus married Nettie Fowler, who became his constant consultant and, upon his death, the first American woman to assume leadership of a major business. His brothers became partners in the firm, and Cyrus turned his attention to the building of a world market. He became active in the Presbyterian Church, establishing McCormick Theological seminary, and also in the Democratic party. His other interests included philanthropy, railroading, mining and Chicago real estate. McCormick died in Chicago on May 13, 1884. In 1902 the McCormick Harvesting Machine company joined with the Deering Harvester company and others to form International Harvester company, with McCormick's son, Cyrus Jr., becoming its first president.

BIBLIOGRAPHY.—William T. Hutchinson, *Cyrus Hall McCormick*, vol. i, *Seed-Time, 1809-1856* (1930), vol. ii, *Harvest, 1856-1884* (1935); Cyrus McCormick, *The Century of the Reaper* (1931). (R. McC.)

MCCORMICK, ROBERT RUTHERFORD (1880-1955), U.S. publisher, editor and soldier, was born in Chicago, Ill., July 30, 1880. His father was a U.S. diplomat, his mother a daughter of Joseph Medill, editor and proprietor of the *Chicago Tribune*.

A graduate of Yale university (1903) and Northwestern university law school, Chicago (1906), McCormick was admitted to the bar in 1908. He served as a Chicago alderman, 1904, and president of the Sanitary District board, 1905-10. As a staff and combat officer with the American expeditionary force (1917-18) McCormick was awarded the U.S. distinguished service medal.

McCormick was named president of the Tribune company in 1911, and with his cousin, Joseph Medill Patterson (*q.v.*), shared the functions of publisher and editor of the *Chicago Tribune* from 1914 until 1925 when he became sole editor and publisher. Under his direction the *Tribune* came to lead the U.S. in standard-size newspaper circulation and the world in newspaper advertising revenue. He built Tribune enterprises to include forest lands, paper mills, hydroelectric installations and shipping companies as well as major publishing, radio and television facilities. Tribune editorial policies voiced outspoken opposition to Prohibition, the Roosevelt and Truman administrations and U.S. political involvement in overseas conflicts. From 1925 until his death April 1, 1955, at Wheaton, Ill., McCormick was among the most powerful and controversial figures in U.S. journalism. A staunch advocate of constitutional liberties, McCormick was the author of historical works, numerous pamphlets, and public and radio addresses. (F. C. Cn.)

McCOY, SIR FREDERICK (1823-1899), British paleontologist, who established and directed the National Museum of Natural History and Geology in Melbourne, Austr., was born the son of Simon McCoy, a physician, in Dublin, Ire., in 1823 and was educated for the medical profession. In collaboration with the geologist Adam Sedgwick, he prepared *A Synopsis of the Classification of the British Palaeozoic Rocks, With a Systematic Description of the British Palaeozoic Fossils in the Geological Museum of the University of Cambridge* (1855). After four years in Belfast, N.Ire., he became professor of natural science in the University of Melbourne, where he lectured for about 30 years. While he directed the National museum he became associated with the geological survey of Victoria as paleontologist and issued, at

intervals during a 30-year span, a series of decades (works in ten parts) entitled *Prodromus of the Palaeontology of Victoria*. He also issued the *Prodromus of the Zoology of Victoria*. McCoy was elected fellow of the Royal Society in 1880 and was made Companion (in 1886) and Knight Commander (in 1891) (of the Order) of St. Michael and St. George. He died near Melbourne on May 13, 1899.

MCCULLOCH, HUGH (1808–1895), U.S. financier, comptroller of the currency, and secretary of the treasury, was born at Kennebunk, Me., Dec. 7, 1808. After two years at Bowdoin college, Brunswick, Me., he taught school, studied law in Boston, and began practising law in 1833 at Fort Wayne, Ind. He was cashier and manager of the Fort Wayne branch of the old state bank of Indiana from 1835 to 1856, and president of the new state bank from 1857 to 1863. Even though he had opposed, on behalf of the state banks, the proposed national banking legislation, he was appointed comptroller of the currency and successfully put the new National Bank act of 1863 into operation. In March 1865 he was appointed secretary of the treasury by Pres. Abraham Lincoln and continued in that office under Pres. Andrew Johnson until March 1869. Following a suggestion made by McCulloch, congress passed an act on March 12, 1866, that provided for a slow withdrawal from circulation of greenbacks (paper money issued during the Civil War). Strong opposition developed, however, and the legislation was repealed on Feb. 4, 1868, after only \$48,000,000 had been withdrawn. After leaving the cabinet McCulloch spent six years (1870–76) in England as a member of the banking house of Jay Cooke, McCulloch and Co. (after 1873, McCulloch and Co.). He was again briefly secretary of the treasury under Pres. Chester A. Arthur (Oct. 1884–March 1885). He lived in retirement near Washington, D.C., and died there May 24, 1895. His reminiscences, *Men and Measures of Half a Century*, was published in 1888. (Jo. F. S.)

MCCULLOCH, SIR JAMES (1819–1893), prime minister of Victoria, Austr., 1863–66, 1866–68, 1868–69 and 1875–77, was born in Glasgow, Scot. After a primary education he was employed by a firm of merchants and on becoming a junior partner was sent to Melbourne in 1853 to organize an Australian branch. He was nominated a member of the legislative council in 1854 and was elected to the legislative assembly in 1856 for Wimmera. He was asked by Gov. Sir Henry Barkly to form a ministry in April 1857 but failed and became minister of trade and customs under W. C. Haines. McCulloch was treasurer in 1859 and formed in 1863 the most stable ministry in Victoria up to that time. This term of office was taken up in the struggle to give expression to the wishes of the electorate for protective tariffs, against the resistance of the legislative council. McCulloch not only eventually succeeded in establishing protection but also demonstrated the essential nature of the problems of the constitution. Gov. Sir Charles Darling made decisions indicating that the views of the vast majority who supported McCulloch's ministry in the elections should prevail, and was recalled to England. A long and bitter struggle took place between the assembly and the council over the proposed grant of £20,000 to Lady Darling. McCulloch's resignation in 1869 was followed by the award of a knighthood. Between 1871 and 1873 he was in London as agent general for Victoria; he was made a Knight Commander of St. Michael and St. George (K.C.M.G.) in 1874 and returned to Victoria, forming his fourth ministry in 1875. Defeated in 1877, McCulloch retired in 1878 and returned to England where he died at Ewell on Jan. 31, 1893. (J. F. C.)

MCCULLOCH, JOHN RAMSAY (1789–1864), Scottish economist and statistician who, with the historian James Mill, helped to propagate the economic ideas of David Ricardo, was born at Whithorn, Wigtownshire, on March 1, 1789. From 1818 he edited the *Scotsman* for a while and also exercised much influence through his contributions on political economy to the *Edinburgh Review*. In 1825 he published his *Principles of Political Economy* and occupied the chair of political economy at the new University college, London, from 1828 until 1832. In 1838 he became comptroller of the stationery office. His *Dictionary . . . of Commerce and Commercial Navigation* (1832) and his *Statistical*

Account of the British Empire (2 vol., 1837) are monumental works and his *Literature of Political Economy* (1845), though showing his earlier prejudices, is a valuable pioneer bibliography. McCulloch died in London on Nov. 11, 1864. (T. W. H.)

MACCUNN, HAMISH (1868–1916), Scottish composer and conductor, baptized John MacCunn, was born at Greenock on March 22, 1868. A pupil of Sir Hubert Parry and Sir Charles Stanford at the Royal College of Music, London, he made his name with the overture *The Land of the Mountain and Flood* (1887) and the opera *Jeanie Deans* (1894). His other operas and stage works include *Diarmid* (1897), *The Masque of War and Peace* (1900), and *The Golden Girl* (1905). He was professor at the Royal College of Music (1888–94), conductor of the Carl Rosa opera company, the Moody-Manners company and Quinlan's opera company, and assisted Sir Thomas Beecham at Covent Garden and His Majesty's theatre (1910–11). His unpublished autobiography is in the Glasgow university library. He died in London on Aug. 2, 1916.

MACDIARMID, HUGH (pseudonym of CHRISTOPHER MURRAY GRIEVE) (1892–), the greatest Scottish poet of the first half of the 20th century, was born in Langholm, Dumfriesshire, on Aug. 11, 1892, the son of a postman, and educated at Langholm academy and Edinburgh university. After service in World War I he became a journalist in Montrose, where he edited three issues of the first postwar Scottish verse anthology, *Northern Numbers* (1921–23). In 1922 he founded the monthly *Scottish Chapbook*, in which he advocated a Scottish literary revival (or "Renaissance") and published the lyrics of "Hugh Macdiarmid," later collected as *Sangschaw* (1925) and *Penny Wheep* (1926). Rejecting English as a medium for Scottish poetry, Grieve wrote in "synthetic" Scots, an amalgam of elements from various dialects and literary sources, and he achieved notable success both in his lyrics and in *A Drunk Man Looks at the Thistle* (1926), an extended rhapsody ranging from investigation of his own personality to exploration of the mysteries of space and time. Later, as he became increasingly involved in metaphysical speculation and accepted the philosophy of dialectical materialism, he found it difficult to express his themes adequately in modern Scots, which has lost most of its intellectual terms, and after writing Scotticized English in *To Circumjack Cencrastus* (1930) and archaic Scots in *Scots Unbound* (1932) he returned to "King's English" and sought to produce "a poetry of fact" in *Stony Limits* (1934) and *Second Hymn to Lenin* (1935), where his treatment of Scottish scenes and social circumstances has all the verve and penetration, though less of the ironic humour and the formal dexterity, of his earlier work in Scots. His later volumes, *A Kist of Whistles* (1948) and *In Memoriam James Joyce* (1955), suffer from his attempt to achieve "a variety great enough to express all the world's," the verse being so crammed with detail that the content distorts the form. For portrait see article SCOTTISH LITERATURE.

MACDONALD, FLORA (1722–1790), Scottish Jacobite heroine who helped the Young Pretender to escape from Scotland after his defeat at Culloden, was the daughter of Ranald Macdonald of Milton, in the island of South Uist (Hebrides). Prince Charles Edward (g.v.) took refuge in June 1746 in Benbecula in the Hebrides where Flora was staying on a visit and his companion, Capt. Felix O'Neal, sought her help. She obtained a passport for herself and party, which included Charles disguised as Betty Burke, "an Irish spinning maid." They landed in Skye where Flora and the prince separated. The boatmen's talk later brought suspicion on Flora and she was arrested and imprisoned in the Tower of London. She was later allowed to live outside under the guard of a jailer and after the Act of Indemnity (1747) she was freed. She married Allan Macdonald of Kingsburgh in 1750 and they emigrated to North Carolina in 1774. Macdonald served the British during the American Revolution and was taken prisoner. His wife returned to Scotland in 1779 and died at Kingsburgh on March 5, 1790.

See A. MacGregor, *The Life of Flora Macdonald* (1882). The so-called *Autobiography* (1870) of Flora Macdonald is spurious.

MACDONALD, GEORGE (1824-1905), Scottish novelist and poet, best known as a writer of Christian allegories and fairy stories, was born on Dec. 10, 1824, at Huntly, Aberdeenshire, the son of a farmer. He was educated at Aberdeen university and Highbury theological college, was Congregational minister at Arundel for a few years, and then a free-lance preacher and lecturer in Manchester and Liverpool. From 1856 when he published his first book, *Within and Without*, a poetic tragedy, he made literature his profession, writing poetry, novels of Scottish life, sermons, allegories and children's books. He died on Sept. 18, 1905, at Ashted, Surrey.

As a writer for adults he is remembered for *Phantastes: A Faerie Romance* (1858) and *Lilith* (1895), both unresolved allegories of man's pilgrimage back to God, and for his three series of *Unspoken Sermons* (1867-89). But Macdonald's greatest claim to immortality is as a writer of allegorical fairy stories which have continued to delight children and their elders. His short fairy tales such as "The Light Princess" were first collected in *Dealings with the Fairies* (1867); his most famous book is *At the Back of the North Wind* (1870); his greatest and most enduring are *The Princess and the Goblin* (1871) and its even better sequel *The Princess and Curdie* (1882).

MACDONALD, JACQUES ÉTIENNE JOSEPH ALEXANDRE, DUC DE TARENTE (1765-1840), French army officer, one of Napoleon's marshals, was born at Sedan on Nov. 17, 1765, the son of Jacobite exiles from the Hebrides. In 1784 he joined an "Irish" regiment in the French service. When the French Revolutionary Wars (*q.v.*) broke out, he was promoted colonel. He was made a general after a success near Lille in Aug. 1793; and after the harder fighting near Tourcoing and Ypres he stood out as second only to J. V. Moreau in the army of the north which conquered Holland.

In May 1798 Macdonald was sent to Italy. Under J. E. Championnet he expelled the Neapolitan army from Rome. Then, after an interval of intrigue, he ousted Championnet from the command at Naples (March 1799) but was ordered north to help the defeated French army of Italy. He took the risk of leading his 30,000 men straight to the Po to relieve Mantua and was cut off by A. V. Suvorov's larger Russian army. In the battle on the Trebbia (June 17-19, 1799) he was wounded, and the army escaped with heavy loss.

Treated as a corps commander by Napoleon Bonaparte in 1800, Macdonald won fame by his winter crossing of the Splügen pass from Switzerland into Lombardy; but after Moreau's disgrace in 1804 Macdonald's enthusiasm for Napoleon was questioned, and he was not given a command again until 1809. Then the "talents and nerve" which Napoleon recognized in him brought vigour to the army of Italy in its march to the Danube (*see* NAPOLEONIC WARS). He led this army in a crushing and costly attack on the Austrians at the battle of Wagram in July and was made a marshal of France and duc de Tarente. His command in Catalonia (1810-11) only injured his health. He did nothing in Lithuania during the campaign of 1812 against Russia; but in 1813 Napoleon left him in command of three corps in Silesia, where a rash offensive by him was routed by Blücher in the battle of the Katzbach (Aug. 26). Having barely escaped alive at the battle of Leipzig (Oct. 1813) he was sent to hold Holland and brought a few troops to northern France. One of the last of the marshals to accept Napoleon's abdication in 1814, he was thereafter loyal to Louis XVIII. In 1815 he commanded the remains of the Waterloo army. He died at Courcelles-le-Roi, Seine-et-Oise, on Sept. 25, 1840. (I. D. E.)

MACDONALD, JAMES RAMSAY (1866-1937), British statesman, first Labour prime minister and one of the founders of the British Labour party. He was born on Oct. 12, 1866, at Lossiemouth, on the east coast of Scotland, the illegitimate son of a maid-servant. His father was reputed to be a farm labourer but Mac-

Donald himself was never a manual worker. His formal education ended at the age of 12, but he remained at the board school for another six years working as a pupil teacher. He then went to Bristol and later to London. In Bristol he first established contact with socialist organizations. In London he was employed by the Cyclists' Touring club and then at 12s. 6d. a week as an invoice clerk in a City warehouse. For three years he worked hard in his spare time for a science degree, but he was forced to abandon this project when his health broke down. Upon his recovery, in 1888, he took a job as secretary to Thomas Lough, a radical politician, and also began part-time journalism. He supported James Keir Hardie's candidature at mid-Lanark in 1888, but did so as a Liberal with socialistic leanings, rather than as a believer in independent Labour politics. But by 1894 he was a member both of the Fabian society and the newly formed Independent Labour party (I.L.P.), and by the following year he had achieved a sufficient reputation as a lecturer and speaker to be asked to stand as I.L.P. candidate for Southampton, where he polled 886 votes.

In 1896 he married Margaret Gladstone, the daughter of John Hall Gladstone, fellow of the Royal society, and the great-niece of Lord Kelvin, another distinguished scientist. His marriage brought him no great affluence, but it enabled him to travel widely during the next few years. At home he served on the London county council and devoted most of his energies to persuading the large trades unions to sponsor a Labour party totally independent of the two other parliamentary parties. The establishment of the Labour Representation committee (L.R.C.) in 1900, following on a resolution of the Trades Union congress in 1899, was a great triumph for MacDonald's ideas and he became the first secretary of the new committee. At the general election of 1900 it won only two victories and MacDonald himself was heavily defeated at Leicester. In the following years his delicate task was the two-fold one of getting enough of the larger unions to support the new party actively, and also to prevent their making it too narrow to gain full national status. In the main he was successful and the reward came at the general election of 1906 when the L.R.C. won 29 seats and MacDonald was elected at Leicester, his vote having grown over three-fold since 1900. The new group was big enough to merit an independent parliamentary existence. MacDonald was from the beginning incomparably the most distinguished parliamentary performer and in 1911 he succeeded James Keir Hardie in the chairmanship of the party, by which time he led a group of 40 members.

When World War I began on Aug. 4, 1914, MacDonald broke the unity of the house of commons with a moderate antiwar speech. The speech had been approved by his colleagues beforehand, but a majority of them quickly swung into support for the war and MacDonald resigned the leadership. For the next four years he was an object of considerable obloquy, but he behaved with courage and dignity, neither retreating from his views nor accentuating differences so as to make a permanent split likely. He paid the penalty by being heavily defeated at Leicester in 1918 and he failed to return to the house of commons for four years, despite a by-election attempt at East Woolwich in 1921.

In 1922, when he was elected for the south Wales mining seat of Aberavon, he found that a great change had come over the house of commons. There was a strong Conservative majority, but the Labour party, with 142 seats, was larger than the combined Liberal factions and it therefore became, for the first time, the main alternative to the government. MacDonald was elected by a narrow margin over J. R. Clynes to lead the opposition. Even at that stage MacDonald was in no ways an extreme socialist, although some of his supporters were misled by his opposition to the war into believing that he was. But MacDonald had long made clear his opposition both to syndicalism and to any form of extraparliamentary action. His socialism was of a highly evolutionary nature, ethical, a little vague and frequently expressed in biological metaphor. In addition he had a high respect for traditional British institutions and a strong desire that the Labour party, under his leadership, should play a full part in their working. As a result he was the best possible leader at the time for a party that was eager to become an instrument of government. He

welcomed men of upper and middle class backgrounds into the party; he urged moderate policies; and he impressed the country as a leader of distinguished appearance, captivating voice and lofty purpose.

The rewards came sooner than had seemed possible. Stanley Baldwin, the prime minister, decided to appeal to the country on a program of tariff reform in 1923. The result was the destruction of the huge Conservative majority. The new parliament of 1923 was made up of 258 Conservatives, 191 Labour members and 158 Liberals. The Tories were still the biggest party but there was a clear majority against the policy on which they had fought the election. H. H. Asquith (afterward earl of Oxford and Asquith), the Liberal leader, decided to offer MacDonald the prospect of the premiership. MacDonald leaped at the opportunity. He secured the approval of the Labour party and of the Trades Union congress, and on Jan. 22, 1924, the man who had never previously held office and was not even a privy counselor, became the first Labour prime minister of Great Britain. Lord Haldane became lord chancellor; Arthur Henderson somewhat reluctantly accepted appointment to the home office; Philip Snowden became chancellor of the exchequer and Lord Chelmsford, a former Indian viceroy who was not a member of the Labour party, became first lord of the admiralty. MacDonald himself took on the foreign office as well as the premiership, and it was in this field that the most notable achievements of the government lay. The Soviet regime was afforded *de jure* recognition; the first negotiated agreement with Germany since the war was reached in the London settlement of the reparations problems; and MacDonald joined with Édouard Herriot, the French prime minister, to initiate the Geneva protocol for security and disarmament. At home the budget met with general approval and an important housing act was passed. After nine months the clumsy withdrawal of a crown prosecution against J. R. Campbell, the Communist editor of the *Workers' Weekly*, led to an adverse vote in the house of commons and MacDonald secured a dissolution of parliament. The ensuing campaign was dominated by the Zinoviev letter scare (see ENGLISH HISTORY), and MacDonald's handling of the incident was open to much criticism. The Labour party increased its popular vote but lost more than 40 seats and the Conservatives regained a clear parliamentary majority. MacDonald resigned on Nov. 4, 1924. There was some murmuring against his party leadership at this stage, but it was not serious and he led the opposition throughout the following parliament.

At the general election of 1929 MacDonald was again successful in dislodging the Conservatives from their position. With Labour the largest single party (287 seats), his claim to office was much stronger than in 1924. Baldwin resigned without waiting to meet parliament and MacDonald became prime minister for the second time on June 5, 1929. Snowden returned to the exchequer; Henderson became foreign secretary; Clynnes was home secretary; John (afterward Lord) Sankey became lord chancellor; and J. H. Thomas was lord privy seal and deputy leader of the house of commons. Foreign affairs were again the government's strong field. A naval treaty for which MacDonald had prepared the ground by a visit to the United States was concluded in 1930, and Henderson was preparing the ground at Geneva for the World Disarmament conference. Home affairs were dominated by mounting unemployment and the growing effects of the worldwide economic slump. MacDonald, in common with most of his cabinet, showed no understanding of the forces at work or of the way in which they might be controlled. At first he appointed J. H. Thomas to co-ordinate antiunemployment measures, but later attempted, equally ineffectively, to do this himself. Budgetary difficulties arose and the May committee, an extraparlimentary body, was appointed to recommend economy measures. By the time of its report, in Aug. 1931, a foreign exchange crisis had added itself to the other problems. Snowden supported the prime minister in demanding full economy cuts, but the majority of the cabinet, led by Henderson, refused to accept the full cuts in unemployment benefit and MacDonald thereupon went to Buckingham palace to resign (Aug. 24). The following day his colleagues were amazed to discover that it was the government and

not the prime minister which was out. MacDonald was retained as head of a coalition cabinet with Tory and Liberal support. Only three members of the former cabinet—Snowden, Thomas and Sankey—followed him. The remainder went into opposition and faced a political massacre at the general election of Oct. 1931.

MacDonald remained as prime minister for over three years but his powers of speech, thought and action soon began to decline and the real power in the government was exercised by Baldwin. MacDonald was not greatly respected by the Conservatives and he was reviled by his former colleagues who regarded his action in 1931 as a betrayal of everything for which he had previously stood. In June 1935, MacDonald exchanged offices with Baldwin and became lord president of the council. At the general election later that year he was heavily defeated in his constituency at Seaham Harbour (to which he had moved in 1929) and had to seek refuge as member for the Scottish universities. He died at sea, on a health visit to South America, on Nov. 9, 1937.

MacDonald's contribution to the rapid rise of the Labour party and its evolution into a party capable of forming a government was unique. He first built up its self-confidence and then, in 1931, gravely damaged it, leaving behind a legacy of suspicion for the party leadership that lasted for some years. As prime minister his greatest achievements lay in the field of international politics.

The most important of MacDonald's political books are: *Socialism and Society* (1905), *Socialism and Government* (1909), *The Awakening of India* (1910), *The Socialist Movement* (1911), *Syndicalism* (1912), *The Social Unrest* (1913), *National Defence* (1917), *Parliament and Revolution* (1919), *Parliament and Democracy* (1920), *The Government of India* (1919), *A Policy for the Labour Party* (1920) and *Socialism, Critical and Constructive* (1921). In addition there is his biography of his wife, *Margaret Ethel MacDonald* (1921), and a volume of essays and travel pictures, *Wanderings and Excursions* (1925).

MACDONALD, SIR JOHN ALEXANDER (1815-1891), first premier (1867-73) of Canada, was born in Glasgow, Scot., on Jan. 11, 1815. His parents emigrated to Canada in 1820, settling at Kingston, Upper Canada (now Ontario), and there Macdonald received his education, studied law and was called to the bar in 1836. He was elected to the assembly of the province of Canada as Conservative member for Kingston in 1844, entered the government as receiver-general in 1847 and went into opposition when the Reformers triumphed in 1848. These were difficult years for his party. To counter Tory extremists in Montreal who signed a manifesto urging that Canada secede from the British empire, Macdonald helped organize the British-American league to promote closer ties with the mother country, the adoption of a national commercial policy and the confederation of the British North American provinces.

In 1854 Macdonald took the lead in shaping a coalition of Conservatives, Reformers interested in state-aided railway construction and French-Canadian members. From this union emerged the Liberal-Conservative party with which Macdonald was henceforth identified. In 1856 he became head of the administration for Upper Canada, and prime minister in 1857 with Georges Étienne Cartier as his colleague and leader for Lower Canada.

During the troubled years of shifting party alignments and domestic and international tensions Macdonald revealed an easy-going, tolerant, resourceful, somewhat unscrupulous personality, also remarkable talents for winning support from influential men and for balancing rival sections and cultural interests. Confronted with parliamentary stalemate, in June 1864 Macdonald and Cartier joined their chief opponent, George Brown, in a new coalition to work for the confederation of the British North American colonies.

Macdonald headed the delegations from Canada which discussed the outlines of the proposed union with public-spirited men from the maritime colonies at conferences at Charlottetown and Quebec, and which later assembled in London to help draft the British North America act. Macdonald had played the leading part in the negotiations and was accordingly appointed first premier of the new dominion; he was created a knight commander of the order of the Bath for his services to the empire.

In his cabinet Macdonald assembled political chieftains who represented Canada's various interests and regions and could act as his agents in maintaining the government's popularity within their sections. His tact and sense of the practical were vital in allaying anticonfederationist sentiment in Nova Scotia and in the speedy, relatively untroubled expansion of the dominion to continental dimensions by incorporating Rupert's Land and the Northwest Territory and establishing Manitoba as a province in 1870, British Columbia in 1871 and Prince Edward Island in 1873. Appointed one of five British plenipotentiaries negotiating the treaty of Washington (1871), his was the difficult, thankless role of upholding Canadian interests against both U.S. and British representatives and afterward of defending the treaty in Canada. Construction of the intercolonial railway link promised the maritime provinces in 1864 was begun. To persuade private capital to undertake the task of building the Pacific railway, an ambitious undertaking the government was pledged to complete by 1881, Macdonald offered lavish assistance in cash and land. The disclosure that Sir Hugh Allan, the recipient of the contract, had given large sums of money to assist the elections of Cartier and Macdonald in 1872 forced Macdonald and his cabinet to resign office on Nov. 5, 1873. His offers to quit the party leadership, however, were rejected by his followers and colleagues.

Macdonald soon found ample occasions for attacking the lacklustre performance of the Liberal government of Alexander Mackenzie in combating the severe depression which had fallen upon the country. During the summer of 1876 Macdonald began agitating for a thoroughgoing protective tariff system to relieve manufacturing and maintain employment. Since the Liberal government continued to proclaim its faith in the principle of free trade and tariff for revenue only, commercial policy constituted the principal issue of the general election of 1878.

Much to the Liberals' surprise, the voters preferred the "old corruptionist" with the dynamic "National Policy" program of nation building, and returned Macdonald to office. Tariffs were raised to protective levels to stimulate textile, iron and steel, and other manufacturing industries. In 1880 a new group of capitalists became interested in building the Pacific railway, postponed by the former government, and, assisted by considerable initial grants as well as by timely loans during construction, they succeeded in driving the steel rails across the continent by November 1885. Times improved slightly and a measure of settlement began to flow into western Canada.

The final years saw Macdonald's skill marshaled against growing political opposition and severe challenges to Canadian unity. In 1885 the prairies blazed with the second Riel, or Northwest, rebellion, caused partly by Macdonald's own negligence. The rebellion, in turn, provoked a series of French-English controversies that convulsed the dominion for years. In 1887 an interprovincial conference linked premiers of Canada's five largest provinces in protest against the supposed favouritism of Macdonald's policies and his alleged encroachment upon provincial constitutional prerogatives. Continued hard times awakened outcries against the protective tariff and renewed appeals for unrestricted reciprocity (free trade) with the United States.

Facing these challenges, Macdonald eased the weight of his protectionist and constitutional programs. But against unrestricted reciprocity, which he felt meant annexation to the United States and national suicide, he rallied his failing strength. "A British subject I was born; a British subject I will die. With my utmost effort, with my latest breath, will I oppose the 'veiled treason' which attempts by sordid means and mercenary proffers to lure our people from their allegiance"—so ran his political manifesto for the general election of March 1891. The people

did not fail the leader who symbolized their national purpose in the face of all obstacles. But the campaign proved too much for the 76-year-old veteran. On May 29 he suffered a stroke of paralysis and, still prime minister of Canada, he died at Ottawa on June 6, 1891.

Macdonald*, 2 vol. (1895, 1930). Brief accounts include G. R. Parkin, *Sir John A. Macdonald*, in "The Makers of Canada Series" (1907, new ed. 1909); Sir Joseph Pope, *The Day of Sir John Macdonald* (1915); W. S. Wallace, *Sir John Macdonald* (1924). (M. ZA.)

MACDONALD, JOHN SANDFIELD (1812-1872), Canadian Liberal politician and statesman, first premier of Ontario, was born on Dec. 12, 1812, at St. Raphael, Glengarry county, Upper Canada (later Ontario). Educated at Cornwall, he was called to the bar in 1840. He represented Glengarry in the legislative assembly, 1841-57, and Cornwall, 1857-72. In 1867 he was elected to both dominion and provincial parliaments. He worked closely with Robert Baldwin, but fell out with Francis Hincks. Politically, he was a moderate, independent, "Eastern Ontario" reformer, and represented a position quite distinct from the Radical, or "Clear Grit," reformers. Yet George Brown included him as attorney general in the "Short" Reform administration of 1858; and from 1862 to 1864 Sandfield Macdonald led the government. He opposed the confederation movement in the period 1864-67, but in 1867 he was appointed premier of Ontario, and in close co-operation with the federal government initiated provincial government. His government was defeated in the Ontario election of 1871. He died at Cornwall June 1, 1872. He was a hardworking man of integrity and independent views but lacked the touch of his great contemporary Sir John A. Macdonald. (P. G. Co.)

MACDONNELL (MACDONELL), ALESTAIR (ALEXANDER) RUADH (c. 1725-1761), chief of Glengarry, a Scottish Jacobite who was later known as Pickle the spy, was born in Scotland probably in 1725, his family being a branch of the clan Macdonald. Alestair ran away when a boy and entered the Royal Scots, a regiment then in French service, and was sent to Scotland as a Jacobite agent in 1744. He was in France in 1745 when Prince Charles the Young Pretender landed in Scotland but was later captured at sea while bringing help to Charles and was imprisoned in the Tower of London for 22 months. He then went abroad, but in 1749 he was again in London and is believed to have acted as spy for the British government, under the name of Pickle, keeping a close watch on Jacobite activities. He died on Dec. 23, 1761.

See Andrew Lang, *Pickle the Spy* (1897) and *The Companions of Pickle* (1898). (W. Fe.)

MacDONNELL, SORLEY BOY (c. 1510-1590), Irish chieftain of Scottish descent who firmly established his power under Elizabeth I and reversed the Tudor policy of diminishing aristocratic privileges, was the son of Alaster (Alexander) MacDonnell, lord of Islay and Kintyre (Cantire). He was born at Ballycastle, County Antrim, and from a marriage in the 15th century between Ian Mor MacDonald and Marjorie Bisset had a claim to the Glens (Glynns), the territory east of the river Bush. Despite the English efforts to master the Scottish settlers in Ulster, Alaster MacDonnell managed to increase the family fortunes by marriage alliances to the O'Neill (q.v.) family and by his position as captain of the O'Neill mercenary forces. Sorley Boy (Somhairle Buidhe) became prominent when he was backed by the government in 1558 to oppose Shane O'Neill's claims to his father's inheritance. Sorley Boy was defeated near Coleraine in 1564 and at Ballycastle in 1565, and both he and his brother, James of Dunyveg, were taken prisoner. James died in captivity and Sorley Boy was kept in subjection for two years. O'Neill was defeated by the O'Donnells of Donegal in 1567 and later died in a quarrel with the MacDonnells, which was instigated by the Dublin government.

Sorley Boy, freed, and unopposed by powerful rivals, built up his family's power from 1568 to 1586 by alliances with the O'Neills and by recruiting family reinforcements from Scotland. Despite the government's efforts to dislodge him he held his own, and

when Francis Drake and Sir John Norris, under the earl of Essex' command (*see* ESSEX, WALTER DEVEREUX), massacred the refugees on Rathlin Island, MacDonnell retaliated by taking Carrickfergus. He later held Dunluce castle for James VI (later James I of Great Britain) of Scotland. Ultimately Elizabeth admitted the MacDonnells as subjects in 1585–86, accepted their allegiance and confirmed Sorley Boy's possession of most of the Route (the land between the rivers Bann and Bush) and his nephew Angus' possession of the Glens. Peace was fully restored by the time MacDonnell died in 1590. (R. D. Es.)

MACDONOUGH, THOMAS (1783–1825), U.S. naval officer, who commanded the U.S. squadron at the battle of Lake Champlain during the War of 1812, was born in Delaware on Dec. 31, 1783. He entered the U.S. navy in 1800. During long service as a lieutenant, he took part in the bombardment of Tripoli and on a subsequent occasion showed great firmness in resisting the seizure of a seaman as an alleged deserter from the British navy, his ship at the time lying under the guns of Gibraltar. When war with England broke out in 1812, he was ordered to cruise in the lakes between Canada and the United States, with his headquarters on Lake Champlain. He was instrumental in saving New York and Vermont from invasion by his brilliant victory of Lake Champlain, gained on Sept. 11, 1814, with a flotilla of 14 vessels carrying 86 guns, over Capt. George Downie's 16 vessels and 92 guns. *See* WAR OF 1812.

McDOUGALL, FRANCIS THOMAS (1817–1886), first Anglican bishop of Labuan and Sarawak, was born at Sydenham, south London, on June 30, 1817; he first qualified in medicine, but took holy orders in 1845, and in 1847 was accepted for service in Sarawak, which had recently become an independent principality under Sir James Brooke. McDougall used both his medical skill and his powers as a preacher to commend the gospel to the three peoples—Malay, Dayak and Chinese—who made up the population of his area. His health and that of his family suffered grievously in the early years of his mission. Numbers of both missionaries and converts gradually increased. Brooke desired that the church in his dominions should be regularly organized under a bishop, and in 1854 McDougall was designated for this office. Grave difficulties were felt as to the constitution of a diocese of the Church of England in what was not strictly British territory; these were at last overcome by giving the new bishop the title of Labuan, the small island which was a British colony. McDougall was consecrated in Calcutta, India, in 1855. During his 13 years' episcopate he laid solid foundations for what later became the flourishing dioceses of Singapore and Malaya, and Borneo. In 1867 he was obliged by ill-health to return to England and in 1868 resigned. Thereafter he held various positions of dignity in the Church of England, and at the time of his death (on Nov. 16, 1886, at Milford, Isle of Wight) he was canon of Winchester and archdeacon of the Isle of Wight.

(S. C. N.)

McDOUGALL, WILLIAM (1871–1938), British psychologist, who did more than any other writer at the beginning of the 20th century to establish British psychology on an experimental and physiological basis. He was born in Lancashire on June 22, 1871, and was educated at school at Weimar, Ger., and at the universities of Manchester and Cambridge, at the latter of which he studied medicine. In 1899 he joined the Cambridge anthropological expedition to the Torres straits, where he applied psychological tests to the native peoples. He then went to Göttingen to acquire a fuller knowledge of experimental techniques from G. E. Müller. McDougall's first important publication described a series of ingenious experiments seeking to reinstate Thomas Young's three-colour theory of vision. He turned next to the study of attention (which he identified with apperception) and its neurological correlates and formulated the hypothesis that the basis of intellectual activities is a hierarchy of neural circuits arranged in four main levels. In his *Physiological Psychology* (1905) and his *Psychology, the Study of Behaviour* (1912) he demonstrated the value of a thoroughgoing biological standpoint in place of the traditional

philosophical approach. In 1901 McDougall joined James Sully as assistant in the new experimental laboratory at University college, London; and in 1904 he accepted a readership at Oxford. There he encouraged research students to apply Sir Francis Galton's method of mental testing to determine the innate factors of individual differences.

In his best-known work (*An Introduction to Social Psychology*, 1908), McDougall developed a theory of human behaviour based on the assumption of inherited instincts with their accompanying emotions and an acquired superstructure of sentiments. In 1920 he accepted the chair of psychology at Harvard university and in 1927 moved to Duke university, Durham, N.C., where, with J. B. Rhine, he continued his earlier studies on extrasensory perception and paranormal psychology. In *Modern Materialism and Emergent Evolution* (1929) and *The Riddle of Life* (1938) he elaborated his hypothesis of interaction between body and soul and drastically criticized the materialistic revival inaugurated by the American behaviourist school and the consequent neglect of purposive factors in human life. He died at Durham, N.C., on Nov. 28, 1938. (Cy. B.)

MacDOWELL, EDWARD ALEXANDER (1861–1908), U.S. composer known for his piano pieces, who helped establish an independent American school. Born on Dec. 18, 1861, in New York city, he first studied there with Teresa Carreño and then went to Paris, where he was a pupil of Antoine Marmontel (1876–78) at the conservatoire. In 1878 he went to Germany to study composition with Joachim Raff at the Frankfurt conservatory and later taught the piano at Darmstadt. In 1882 Raff introduced MacDowell to Liszt, who arranged for him to play his first *Modern Suite* at the Allgemeiner Musikverein at Zürich on July 11, 1882. In 1884 he went to the U.S., where he married his former pupil, Marian Nevins (1857–1956). He returned with her to Wiesbaden and remained there until 1887. The following year he settled in the U.S. On March 5, 1889, he played in New York city the first performance of his second Piano Concerto in D minor, his most successful larger work.

In 1896 he was invited to establish a department of music at Columbia university, New York. He undertook the task with enthusiasm but was frustrated in carrying out his plans. As a result of disagreement with the university authorities he resigned in 1904, unfortunately becoming the subject of much unpleasant publicity. His mental balance was gravely undermined; this led to a collapse and eventually to a recession to infantilism from which he never recovered. A public appeal for funds was made on his behalf in 1906, but he died in tragic conditions in New York city on Jan. 23, 1908. After his death his widow organized the MacDowell colony at their residence in Peterborough, N.H., as a permanent institution in the form of a summer residence for American composers and writers.

MacDowell's music derives from the contemporary romantic movements in Europe. His lyrical style suggests Grieg, and his harmony, Schumann and sometimes Liszt. Almost all his works have literary or pictorial associations. His early symphonic poems include *Hamlet and Ophelia* (1885), *Lancelot and Elaine* (1888), *Lamia* (1889) and *The Saracens* (1891). More distinctive is his orchestral *Indian Suite* (1892), depicting American Indian life and rituals and based on authentic Indian tunes. His songs, though derivative, are genuinely lyrical, but he is at his best in his piano music, particularly in small pieces when he shows the gifts of a sensitive miniaturist. The best of his piano works are the suites *Sea Pieces* (1898) and *Fireside Tales* (1902) and the imaginative evocations of the American scene in the albums *Woodland Sketches* (1896) and *New England Idylls* (1902). His four piano sonatas, *Tragica* (1893), *Eroica* (1895), *Norse* (1900) and *Keltic* (1901), are ambitious attempts at programmatic music in classical forms.

See L. Gilman, *Edward MacDowell* (1909); Marian MacDowell, *Random Notes on Edward MacDowell and His Music* (1950).

McDOWELL, EPHRAIM (1771–1830), U.S. surgeon who performed the first successful ovariectomy (removal of an ovarian tumour) and thus demonstrated the feasibility of elective ab-

dominal operations. He was born in Rockbridge County, Va., on Nov. 11, 1771, but spent most of his youth in Danville, Ky., where his family settled in 1784. He received his preliminary schooling at seminaries in Georgetown and Bardstown and then studied under a physician as a preceptor in Staunton, Va. After studying in Edinburgh in 1793-94, he returned to the U.S. and in 1795 began to practise in Danville, which then had fewer than 1,000 inhabitants. There in Dec. 1809 he undertook the operation that previously had been generally considered impossible. Without anesthesia or antisepsis, he removed a 20-lb. ovarian tumour from Mrs. Jane Todd Crawford, who survived the operation for more than 30 years. McDowell operated upon two additional patients before he made his first report in the *Eclectic Repertory and Analytical Review* in April 1817. His article was met with skepticism and disbelief. He continued, however, to perform the operation and completed 13 prior to his death in Danville on June 25, 1830.

MACDUFF, a small burgh and seaport of Banffshire, Scot., on the Deveron, 1 mi. E. of Banff and 46 mi. N.W. of Aberdeen by road. Pop. (1961) 3,478. The site, occupied by the fishing village of Doune (or Down), was purchased by the 1st earl of Fife, about 1732, and the name was later altered to Macduff by the 2nd earl. In honour of its constitution as a burgh in 1783 he rebuilt the market cross in front of the parish church. Behind it is a World War I memorial in the shape of a tower 70 ft. high. The harbour is safer and more accessible than that of Banff. The inhabitants are chiefly employed in the whitefish industry and in boatbuilding. New Fishmarket buildings were opened in 1955. Grain and fish are exported and coal imported. A stone bridge across the Deveron connects with Banff.

McDUFFIE, GEORGE (1790-1851), U.S. congressman, state governor and strong advocate of states rights, was born on Aug. 10, 1790, near Augusta, Ga. He graduated from South Carolina college, Columbia, in 1813 and began to practise law the next year. In 1818 he was elected to the state legislature and in 1821 to the U.S. house of representatives. At first a nationalist favouring internal improvements, he soon became a strict constructionist and vigorous opponent of the protective tariff. He played a leading role in drafting the "tariff of abominations" in 1828, and then advocated nullification, the doctrine that a state could nullify within its borders any federal law that it regarded as unconstitutional. Not content with Calhoun's "short of war" exposition of 1828, he spoke at Charleston on May 19, 1831, with such force and logic as to drive Calhoun (then vice-president of the United States) into open advocacy of nullification. A national crisis ensued and the protective tariff of 1832 was replaced by the compromise tariff of 1833.

McDuffie served as governor of South Carolina from 1834 to 1836; he urged the South to carry on direct trade with Europe and visited England in 1839. In Dec. 1842, he returned to the senate to battle the protectionist Whigs, who were in power. In 1846 McDuffie returned in ill health to Cherry Hill, Sumter district, S.C., where he died, March 11, 1851. (T. P. MA.)

MAÇE, originally a weapon of offense, made of iron or steel, capable of breaking through armour. The mace was carried in battle by medieval bishops (Odo of Bayeux is represented on the Bayeux tapestry wielding one) instead of the sword, so as to conform to the canonical rule which forbade priests to shed blood. It continued in use as a weapon until the late 16th century, though many of the later examples with elaborately pierced flanges and damascened shafts seem to have been carried as a sign of rank. The Turkish mace (*pushkan*), with an almost spherical head of iron sheathed in silver gilt, was also used in the 17th century in eastern and northern Europe, mainly in those countries under Turkish domination, as a symbol of authority. The earliest ceremonial maces, as they afterward became, though at first intended to protect the king's person, were those borne by the sergeants at arms, a royal bodyguard established in France by Philip II and in England probably by Richard I. The history

BENTHAM W. CHAPMAN, © MANSION HOUSE, LONDON

MAÇE (SCEPTRE) OF LORD MAYOR OF LONDON; HEAD DATES FROM 15TH CENTURY

of the civic mace in England (carried by the sergeants at mace) begins about the middle of the 13th century, though no examples of that period exist today. Ornamented civic maces were considered an infringement of one of the privileges of the king's sergeants, who, according to the commons' petition in 1344, were alone deemed worthy of having maces enriched with costly metals. This privilege was granted, however, to the sergeants of London and later to those of York (in 1396), Norwich (in 1403-04) and Chester (in 1506). Maces covered with silver are known to have been used at Exeter in 1387-88; two were bought at Sandwich in 1435 and others for Launceston in 1467-68. In the next century several other cities and towns had silver maces, and in the 16th century they were almost universally used.

The mace was carried as a symbol of royal authority, and for this reason the royal arms were set on the button at the end of the handle. During the 15th century this button was greatly expanded in size, in order to give due prominence to the royal arms. Thereafter it was surrounded by a coronet, which by the 17th century developed into an arched crown. At the same time the flanges of what had been the head dwindled into decorative brackets, and the mace was carried upside down with the crown uppermost, what had started as the head being held in the hand. As the custom of having sergeants' maces ceased, the large maces borne before the mayor or bailiffs came into general use.

In 1649 it was decided that the house of commons should have a mace of approved design. This was furnished by Thomas Maundy, who supplied many others of the same pattern for provincial towns. This pattern remained standard in England thereafter, with the exception that at the Restoration the royal devices were replaced on the head. There are two maces in the house of lords, the earlier dating from the reign of Charles II. Historic silver maces of the 18th century include the one of 1753 at Norfolk, Va., and that of 1756 of the state of South Carolina.

Among other maces, more correctly described as staves, in use at the present time, are those carried before ecclesiastical dignitaries and clergy in cathedrals and parish churches, and the maces of the universities. The silver mace with crystal globe of the lord high treasurer of Scotland, at Holyrood palace, Edinburgh, was made about 1690. The remarkable mace or sceptre of the lord mayor of London is of crystal and gold and set with pearls. The head dates from the 15th century, while the mounts of the shaft are early medieval.

MACEDO, JOSÉ AGOSTINHO DE (1761-1831), Portuguese didactic poet and a critic and pamphleteer notable for his acerbity. Born at Beja, Sept. 11, 1761, he became professed as an Augustinian in 1778. Because of his turbulent character he spent much time in prison and was constantly transferred from one community to another. In 1792 he was unfrocked but obtained a papal brief which gave him the status of a secular priest. He was soon recognized as the leading pulpit orator of the day and in 1802 was appointed one of the royal preachers.

The best examples of his didactic poetry are *A Meditação* and *Newton* (1813). In 1814 he produced *O Oriente*, an insipid epic dealing with Vasco da Gama's discovery of the sea route to India. He also founded and wrote for a large number of journals, and the tone and temper of these and of his political pamphlets caused one of his biographers to call him the "chief libeler" of Portugal.

His malignity reached its height in a satirical poem in six cantos, *Os Burros* (1812-14), in which he pilloried, by name, men and women of all grades of society, living and dead, with the utmost licence of expression. From c. 1823 onward he was the virulent champion of the absolutist reaction. He died at Pedrouços, Oct. 2, 1831.

(N. J. L.)

MACEDONIA, the central part of the Balkan peninsula, lying athwart the political frontiers of Yugoslavia, Greece and Bulgaria. In historical times, from the Roman conquest of the ancient kingdom of Macedonia (q.v.) to the 20th century, the area has been strategically important as a crossroads. The Via Egnatia, the shortest Roman route between the Adriatic coast and the Bosphorus, passed through places now known as Bitola (Yugoslavia) and Salonika (Greece). The valley of the Vardar (Axios) river was and continues to be the easiest highway from Salonika to the north. Both the Roman (Byzantine) and the Ottoman empires based on Constantinople considered it essential to hold Macedonia, through which Serbia, Bosnia, Albania and continental Greece could be reached. This stretch of land had, therefore, a complex history and, as a result, a mixed population. When in the 19th century the national consciousness of the Balkan peoples began to waken, Macedonia became a problem of international magnitude. (See MACEDONIAN QUESTION.)

Physical Geography.—Macedonia is bounded on the east by the lower Mesta (Nestos) river and by the western slopes of the Rhodope (Rodopi) upland. North of the Pirin massif the boundary turns west, passing south of Kyustendil (Bulgaria), by the Siroka Planina, Crna Gora and Sar Planina. Thence it turns southward by the Korab and Jablanica range and lakes Ohrid (2,280 ft.) and Prespa (2,799 ft.) to the massif of Grammos (8,033 ft.); then eastward, embracing the whole basin of the Aliakmon (Bistritsa) river and reaching the Gulf of Salonika near Mt. Olympus. Including the Khalkidhiki (Chalcidice) peninsula, Macedonia covers an area of about 25,700 sq.mi. It is not, however, a geographic entity.

Yugoslav or Vardar Macedonia.—This is the People's Republic of Macedonia (9,928 sq.mi.), one of the six component parts of the Federal People's Republic of Yugoslavia (q.v.). It is divided from Greek Macedonia by the Kozuf and Nidze ranges with Mt. Kajmakalan as the highest peak (8,271 ft.). With the exception of the Vardar valley, lower Bregalnica valley and lower Crna valley, this part of Macedonia is a plateau lying from 2,000 ft. to 3,000 ft. above sea level, with mountain massifs reaching 8,331 ft. (Jakupica). The climate approaches the continental type, with summer rains and often copious winter snowfalls. Chief crops are wheat, barley, maize, rice and tobacco, while extensive pastures support large flocks of sheep and cattle. There is also a considerable mineral wealth.

Greek or Aegean Macedonia.—The coastal belt along the Aegean sea, with the wide flat and almost treeless *kampania* of Salonika and the plains of lower Strymon (Struma) river and of Kavalla, has a Mediterranean climate, and its agricultural products are varied. They include wheat, barley, rice and fruit, especially figs and grapes, as well as such industrial crops as tobacco and cotton; there are also mulberry trees for silk production.

Bulgarian or Pirin Macedonia.—This is the *okrug* or district of Blagoevgrad (formerly Gorna Djumaya), the smallest of the three parts of Macedonia (2,509 sq.mi.). It lies north of a belt of mountains through which the gorges of the Struma and Mesta rivers are the only highways to the south. While in the valleys climatic conditions are somewhat Mediterranean, the wild Pirin massif lying between them is snowbound in winter. The Belasitsa (Gr. Oros Kerkini) range, with a peak reaching 6,655 ft. (Radomir), is a natural frontier boundary between Aegean and Pirin Macedonia, and the Maleshevska and Osogovska ranges, with peaks reaching 6,310 ft. (Kadiytza) and 7,386 ft. (Ruen), are the boundary between Pirin and Vardar Macedonia. The only highway leading westward

from the former to the latter is the Strumeshnitsa (Yugos. Strumica) valley, parallel to the Belasitsa range.

Population.—Yugoslav Macedonia comprises the great majority of the Macedonian people, whose Slavonic language is more akin to Bulgarian than to Serbo-Croatian. The 1961 census revealed a population of 1,404,883, including 893,247 Macedonians (64.1%); of the rest, the major groups were Albanians (17%) and Turks (8%).

According to the census of 1961, there was a population of 1,890,654 in the Greek province of Macedonia, overwhelmingly Greek by nationality and language, with only about 80,000 "Slavophones" (65,000 Macedonians and 15,000 Pomaks or Bulgarian-speaking Muslims).

The population of Bulgarian Macedonia amounted in 1956 to 281,015; of this total 83% were described as Bulgars, no Macedonian nationality being recognized in Bulgaria.

See also references under "Macedonia" in the Index.

(K. Sm.)

MACEDONIA, KINGDOM OF. The boundaries of the ancient Macedonian kingdom varied; but it was always centred on the plain in the northeastern corner of the Greek peninsula, at the head of the Thermaic gulf.

Prehistory.—The cultural links of prehistoric Macedonia were mainly with Greece and Anatolia. The people who arrived in the Late Neolithic period (c. 2650-2500 B.C.) were perhaps of Danubian, but more probably of Anatolian, origin; and the newcomers who from 2500 onward gradually imposed the uniform culture of the Early Bronze Age from the peninsula of Chalcidice to Epirus and Thessaly were certainly from northwest Anatolia. Transition from Early to Middle Bronze Age in Macedonia was peaceful (1900). Similarly the matte-painted pottery found throughout Macedonia and Chalcidice in the Late Bronze Age (1500) developed without a break from what went before, though both areas show Mycenaean influence. An irruption of a northern people of the Lausitz (Bohemia) culture into the Axios (Vardar) valley about 1150 was short-lived. From about 1050 in the Early Iron Age Protogeometric ware points to Greece, but its persistence long after similar styles have been superseded there indicates the fall of a curtain which was only lifted with the founding of the first Greek colony in Chalcidice in the 8th century. Of these early peoples, the Neolithic reveal a highly developed aesthetic sense, but their successors are unenterprising in both artistic and material achievement; their remains permit almost no conclusions about their beliefs.

The continuity in the archaeological record suggests that the Early Bronze Age people were the ancestors of the historical Macedonians. The nationality and language of these are both disputed, but the weight of evidence points to their belonging to the family of Greek-speaking peoples, though they may have absorbed various subject tribes with Thracian or Illyrian affinities.

The Argeads to 336 B.C.—From about 700 onward the people who called themselves Macedonians pushed eastward from their home on the Haliacmon (Aliakmon) river under King Perdiccas I and his successors, seized Eordaea and dispossessed the Pierians, Bottiaeans and other tribes of the plain. Aegae (Edessa, q.v.) became the capital, and by the reign of Amyntas I (6th century) Macedonian power extended beyond the Axios to dominate the Thracian tribes in Mygdonia and Anthemous behind Chalcidice. Amyntas enjoyed relations with the Pisistratids at Athens; after Darius' expedition across the Danube (513) he had to become a Persian vassal.

His successor, Alexander I (before 492-c. 450), was obliged to accompany Xerxes against Greece (480), though he secretly aided the Greek allies. Xerxes perhaps helped him to tighten his control over the western princes of Lyncestis, Elimiotis and Orestis, who later used every opportunity to reassert their independence. Alexander seized the Greek colony of Pydna, and advanced his frontiers eastward to the Strymon, taking in Crestonia and Bisaltia; with the rich silver deposits of Mt. Dysorus (mod. Krousia Oros) he issued a fine coinage. It was probably Alexander who organized the mass of his people as a hoplite army called *pezhetairoi*, "foot-companions," with rudimentary political rights, to act as

a counterweight to the nobility, the cavalry *hetairoi* or "companions." His byname, the Philhellene, indicates his efforts to win Greek sympathies. He spread the legend deriving his Argæid house from the Temenids of Argos, thus obtained admission to the Olympic games; from Persian spoil he erected a golden statue at Delphi; and he entertained Pindar at his court. But Athenian ambitions around the Strymon embittered previously cordial relations with Athens.

Alexander's son, Perdiccas II (c. 450-c. 413), asserted his succession against various brothers, of whom Philip enjoyed Athenian help. Angered at the founding of Amphipolis (437/436) Perdiccas used the Athenian clash with Potidaea (432) to unite the Greek cities of Chalcidice in a federation centring on Olynthus; and he twice broke the peace which Athens forced him to make. When the Spartan Brasidas marched north, Perdiccas enlisted his help against Arrhabæus of Lyncestis; then fearing the power of Sparta he reduced his assistance and returned to the Athenian fold. He died about 413, having perfected the technique of playing off the Greek powers one against the other.

Perdiccas' son Archelaus (413-399; *q.v.*) adopted a strongly philhellenic policy, introducing Greek artists to his new capital at Pella. He strengthened Macedonia by building roads and fortresses, improving army equipment and encouraging city life; but his assassination in 399, followed by seven years of murder and anarchy, indicates that his reforms had contributed nothing to political stability. There followed him in rapid succession his assassin Cateuas, his own infant son Orestes, the latter's guardian Aeropus, who removed him, and was reigning when Agesilaus marched through Macedonia in 394), and on his death Amyntas II, a bastard son of Archelaus. Dardas, a prince from Elimiotis, murdered Amyntas. His successor Pausanias, Aeropus' son, was dethroned by a great-grandson of Alexander I, Amyntas III (393/392-370, 369).

Amyntas was expelled from Macedonia by the Illyrians, having received little help from a treaty with the Chalcidic league; on his return he allied himself with the Spartans who, after three years' campaigning (382-379), dissolved the league and so allowed him to regain lost territories from Olynthus. Later he made treaties with Athens and Jason of Phærae; in 370/369 he died. An aggressive policy in Thessaly caused the death of his son Alexander II within a year. His assassin Ptolemaeus reigned as guardian for Alexander's two brothers, Perdiccas III and Philip II; but Perdiccas killed him (365), ascended the throne and made an Athenian alliance against Thebes. After Athens took Pydna and Methone, however, he aligned himself with Amphipolis. Profiting from the general confusion in Greece that followed the battle of Mantinea (362) Perdiccas seized Lyncestis, but in 359 died fighting the Illyrians.

In this crisis his brother Philip assumed control in the name of the infant heir, Amyntas; but having restored order he put Amyntas aside and as king in his own right raised Macedonia to a predominant position throughout the whole of Greece (359-336; see PHILIP II). Our main knowledge about the Macedonian monarchy derives from this period. It was a popular, almost Homeric constitution, limited in power by a strong nobility and a free, outspoken peasantry. The eldest inherited; but the people in arms had the right to acclaim the new king and also to act as a court of appeal. Foreign policy remained a royal prerogative.

Alexander and the Successors, 336-280 B.C.—Philip's son Alexander III (336-323) overthrew the Persian empire and carried Macedonian arms to the Nile and the Indus (see ALEXANDER III THE GREAT). On his death at Babylon his generals divided up the territories of his empire and used them as bases in a struggle to acquire the whole. From 321 to 301 warfare was almost continual between those struggling to maintain the unity of the empire and those who, like Ptolemy, saw that it must disintegrate and were resolved to profit from its dissolution. Alexander's half brother Philip III Arrhidaeus and his son Alexander IV furnished a nominal focus for loyalty down to 317/316, but the real power lay in the hands of the generals. Macedonia itself remained the heart of the empire and its possession (along with the control of Greece) was keenly contested. Antipater was confirmed in the control assigned to him

during Alexander's absence in Asia, and he crushed the Greek rising which followed Alexander's death (322); his coalition with Ptolemy secured the defeat and death of Perdiccas (321), and having been declared regent at Triparadisus he held this office till he died (319). His son Cassander, allied with Antigonos I Monophthalmos in Asia, fought a war against Polyperchon and Eumenes, who claimed to represent the kings; Antigonos defeated and executed Eumenes (316), and in 317 Cassander seized Athens and expelled Polyperchon from Macedonia. He then set about recovering Greece, leaving Philip III and his wife Eurydice in Macedonia; but Olympias, the mother of Alexander the Great, on Polyperchon's instigation invaded Macedonia from Epirus and destroyed both Philip and Eurydice. Cassander quickly recovered Macedonia and had Olympias executed for treason (316). As effective master of Macedonia he now founded Cassandria and Thessalonica (Salonica), and in Greece he refounded Thebes. Between 315 and 312 he combined with Ptolemy and Lysimachus to thwart the ambitions of Antigonos who, since Philip III's death, embodied the hopes of reuniting the empire. By a peace in 311 Cassander lost much of Greece, but strengthened his hold on Macedonia; he then murdered Alexander IV, the surviving king.

In 307 Antigonos' son Demetrius I (*q.v.*) (Poliorcetes) liberated Athens from the tyranny of Demetrius Phalereus, thus giving his father a Greek base. After gaining most of central Greece and part of the Peloponnese he reinstituted Philip II's Hellenic league against Cassander (303/302). But Cassander followed Antigonos' lead by assuming the title of "king of the Macedonians" and revived the coalition against Antigonos, who in 301 perished at the battle of Ipsus. This confirmed Cassander's authority and led to the restoration of his power in Greece. Henceforth the reuniting of the empire was no longer a practical issue. Cassander's death threw Macedonia into confusion (298/297). His son Philip IV died soon after, and the division of the kingdom between his other sons Antipater and Alexander V led to civil war. In 294 Demetrius Poliorcetes, again master of Athens, was called in by Alexander, but promptly murdered him and took the kingdom for himself. Demetrius ruled Macedonia for six years; he annexed Thessaly and central Greece, and founded a new capital at Demetrias on the site of Pagasæ. But in 288 the other dynasts united against him; while Ptolemy stirred up Greece, Lysimachus and Pyrrhus (*qq.v.*) invaded Macedonia. Demetrius' army deserted to Pyrrhus; he himself fled; and Macedonia was partitioned between Pyrrhus and Lysimachus. Soon, however, Lysimachus succeeded in expelling Pyrrhus, and having added western Macedonia and Thessaly to his share ruled alone until his defeat and death at Corupedium in 281. His conqueror Seleucus was, however, stabbed to death by Ptolemy Ceraunus, a son of Ptolemy I of Egypt and a grandson of Antipater, who now seized the Macedonian throne.

The Antigonids, 277-168 B.C.—In 280/279 Galatian marauders invaded Macedonia and defeated and decapitated Ceraunus. For two years the only government and defense was that provided by the separate towns; then in 277 Antigonos II Gonatas, the capable son of Demetrius (now dead), having come to terms with Antiochus I of Syria, seized a base in the Chersonese, and after defeating a Galatian band at Lysimachia in Thrace was hailed king by a Macedonian army (perhaps not until early 276). Under him the country acquired a stable monarchy. From 277 to 168 the Antigonid dynasty ruled Macedonia. Their relations with the people and army-assembly remained much like those of the Argæids. Ceremony was slight; the king was first among his peers and esteemed for his prowess in the hunt, in battle and at the drinking table. Under the Antigonids the outer districts, where separatism still existed, were controlled by *strategi*, "generals"; *epistatai*, "overseers," were placed in many cities. Like other Hellenistic kings the Antigonids consulted a royal council of "friends," but heeded their advice only when they wished. The population remained mainly agricultural (except in cities like Beroea and Pella and the Greek coastal towns); the economy was backward; and mines and forests were a royal monopoly.

Early in Gonatas' reign a Greek rising under Areus of Sparta reduced his control of Greece to a handful of towns, and in 274 Pyrrhus, back from Italy, annexed western Macedonia. But

Gonatas soon recovered control, and on Pyrrhus' death (272) his position was unassailable. The Chremonidean War (267/266–262), a Greek revolt led by Athens and Sparta and inadequately fostered by Ptolemy II, ended in a victory for Gonatas, who perhaps then acquired Atintania from Alexander II of Epirus. His decisive naval victory over Ptolemy II at Cos, which fell then or a little later, gave him control of the Aegean. But an attempt to win Cyrene failed with the murder of his half brother Demetrius the Fair by Berenice, the future consort of Ptolemy III. Shortly afterward his governor of Corinth, Alexander, son of his half brother Craterus, was incited by Ptolemy to revolt (250/249). This cut off the Peloponnese, where the Achaean league made great headway under Aratus, who with Egyptian subsidies directed a campaign against the tyrants fostered by Gonatas in southern Greece. Though in 245 Gonatas recovered Corinth from Alexander's widow by a trick, he lost it to Aratus in 243 and his counter-measures in conjunction with the Aetolians proved a failure. In 240/239 he died. His resilience and solid work had restored to Macedonia a sound and durable government.

His son Demetrius II (*q.v.*; 240/239–229) at once became involved in a war with the Achaean and Aetolian leagues which lasted until his death. Macedonia was weakened and his heir, Philip V, was a child. Antigonos Doson, the son of Demetrius the Fair, became Philip's guardian. He decisively defeated and expelled the Dardanians, recovered the Thessalian provinces annexed by the Aetolians (except Phthiotic Achaea), and at the threat of an army mutiny assumed the kingship as Antigonos III. An expedition to Caria established connections which outlasted his reign, but the navy then fell into decay. In 224 Aratus offered him Acrocorinth as the price for help against Cleomenes III of Sparta, who threatened to destroy the Achaean league; he marched into Greece, and after defeating Cleomenes at Sellasia (222) re-established the Hellenic alliance as a confederacy of leagues, with himself as president. An Illyrian invasion then called him north, and after a victory he died in 221 leaving Demetrius II's son Philip to succeed. Doson had restored internal stability and re-established Macedonia in a stronger position in Greece than it had enjoyed since Gonatas lost Corinth.

Under Philip V (221–179) Macedonia first clashed with Rome. Until 217 Philip was engaged in successful warfare against a coalition of Sparta, Elis and Aetolia, during which he overthrew the council of guardians left by Doson and asserted his personal authority over the army. In 217 he captured the Dardanian capital, Bylazora (Titov Veles). Incited by Demetrius of Pharos, an Illyrian prince in flight from the Romans, he set out to attack the Roman client-states in Illyria, and confirmed his purpose by an alliance with Hannibal (215). Despite an Aetolian alliance (211) the Romans fought the ensuing war ineffectively, and in 206 Philip forced Aetolia to make a separate peace; in 205 the peace of Phoenice ended the Roman war in Philip's favour. He made minor concessions but kept his Illyrian conquests and Atintania. The war consolidated Macedonia in relation to both the Greek alliance and the northern frontiers, and by such measures as the enrollment of new citizens at Larissa Philip had secured the southern gateway to Macedonia. He now turned eastward, perhaps influenced by Antiochus III's return from a triumphant expedition in central Asia. He intrigued against the Rhodians who policed the seas, and embarked upon a program of aggression against the Greek cities of the Aegean and the northeast. He also secretly conspired with Antiochus to plunder the dominions of the child Ptolemy V. Though Rhodes and Pergamum scored a slight advantage over him at Chios, he defeated the Rhodians at Lade (201); but Rhodian and Pergamene envoys contributed to the Roman decision to make war on him (200).

Philip had seriously miscalculated. The conclusion was foregone, and the defeat of Cynoscephalae (197) led to a peace which confined him to Macedonia, depriving him even of Thessaly. Already the Hellenic alliance had fallen apart; now a series of leagues were established in former Macedonian areas. Orestis was independent; once again Lake Lychnidus (Ohrid) formed the western frontier; and Macedonia lost its fleet. Above all, the equilibrium established in 301 had vanished: Rome was the decisive

power in the eastern Mediterranean. Between 197 and 189 Philip collaborated loyally with Rome against Nabis and Antiochus; he recovered parts of Thessaly and his remaining tribute was remitted. Until his death in 179 he concentrated on consolidating Macedonia, and despite successful denunciations at Rome by his neighbours, he amassed wealth, crushed internal opposition and issued new currencies both national and local, the latter reflecting a new policy designed to capitalize regional feeling. Three campaigns advanced Macedonian power in the Balkans (184, 183, 181); but at home he let Perseus, his elder son, persuade him to execute the younger, Demetrius, as a traitor. Those years of adversity revealed Philip's more admirable qualities. His death left a full treasury and an impressive army for the final struggle with Rome. Perseus (*q.v.*), Philip's successor, reigned for 11 years (179–168). He courted favour in Greece, cultivating the revolutionary party in Aetolia, Thessaly and elsewhere. By 172 when Eumenes II of Pergamum successfully incited Rome to war many saw in him the champion of Greek freedom. But Perseus failed to deploy his full resources; the 6,000 talents which Lucius Aemilius Paulus found in his treasury after the battle of Pydna (168) might have bought Illyrian help and saved the Epirote alliance. Neither Philip nor Perseus had been a real threat to Rome, but both had failed to adapt themselves to Roman predominance.

Roman Macedonia.—From 168 to 146 Macedonia formed four independent republics with representative assemblies and annual magistrates, but no common bonds. Tribute was halved, and the mines, at first closed, were re-opened in 158. After the suppression of a revolt led by Andriscus, an alleged son of Perseus (152–148), Macedonia became a Roman province with the four sections as administrative units, and the supervision of such parts of Greece as from time to time forfeited their independence. Macedonia was still the bulwark of Greece, and the northern frontiers saw frequent campaigning against the Scordisci, Maedi and Dardanians. After Caesar's death Macedonia was a base for Brutus and Cassius; in 27 B.C. it became a senatorial province separate from Achaia (Greece). A Macedonian league with high priests and an imperium cult appeared under Claudius I; it had some political functions and embraced Thessaly. Toward A.D. 400 the province was divided into Macedonia and Macedonia *secunda* (or *salutaris*), in the diocese of Moesia.

MACEDONIAN QUESTION, the name given to the historic problem of drawing international frontiers across or around Macedonia (*q.v.*), where strategic or economic considerations cannot easily be reconciled with ethnic considerations.

The Middle Ages, to the 14th Century.—The population of the ancient kingdom of Macedonia seems to have been largely Greek-speaking, with Thracian and Illyrian admixtures; but after the constitution of the Roman province of Macedonia in the 2nd century B.C. some Latin element may have been introduced. When the Roman empire was divided in the 4th century A.D. into eastern and western halves, Macedonia was assigned to the eastern half, which, as the Byzantine empire, with its capital at Constantinople, was long to survive its western counterpart. By this time the population was largely Christian; and its ethnic composition was influenced by the invasions of Goths, Huns and Avars. The arrival of the Slavs in the Balkans, however, led to a far-reaching reorganization of Macedonia, where few towns were left Greek. The Bulgars began to follow the Slavs in the 7th century, and in the 9th century almost all Macedonia, except Salonika, was included in the first Bulgarian empire; but the Bulgars themselves became very largely slavized. On the decay of the first Bulgarian empire in the second half of the 10th century the four sons of a local count, Nicolas, set themselves up as the dynasty of the Comneni.

in Macedonia; and one of them, Samuel, founded the empire sometimes described as the West Bulgarian, which comprised much of the Balkan peninsula. This was destroyed by the Byzantine emperor Basil II, who in 1018 brought all its territory back under Byzantine rule. (See BULGARIA: History.)

Migratory movements and invasions continued. Nomadic Vlachs found in Macedonia a region well suited to their mode of life. Turkic invaders, called Polovtsy by the Slavs and Kumans by the Greeks, were crossing the Danube and entering Byzantine domains; some of them settled in Macedonia and were later known as Vardariotes. While the brothers Ivan and Peter Asen were laying the foundations of the second Bulgarian empire, the Normans under William II of Sicily captured and sacked Salonika (1185). After the diversion of the fourth crusade to Constantinople in 1204, a Latin kingdom of Salonika was set up; but this was overthrown in the 1220s by Theodore Angelus, the Greek despot of Epirus, who thereafter ruled over most of southern Macedonia and styled himself emperor of Salonika in opposition to the Greek emperors of Nicaea. Theodore Angelus was in turn defeated in 1230 by the Bulgarian tsar Ivan Asen II, who then annexed southern Macedonia, except Salonika, to his own dominions; but the Bulgars were themselves defeated in 1246 by the Nicaean emperor John III Vatatzes, who then took for himself not only southern Macedonia but also much of what had been Bulgarian since the beginning of the century. In the 1280s the Serbs began to encroach on western Macedonia; and after their victory over the Bulgarian tsar Michael Shishman (1330) their ruler Stephen Dushan could pursue a series of campaigns against the Byzantines (Greek rule in Constantinople had been restored by the Nicaeans in 1261). By 1346, when Stephen Dushan was crowned "tsar of the Serbs and Greeks" at Skopje, all Macedonia except the vicinity of Salonika was in Serbian hands.

Turkish Rule.—The Ottoman Turks, meanwhile, had already begun to make incursions into the Balkans. They held most of Macedonia by 1371; and their victory at Kosovo in 1389 sealed the fate of the Serbian empire. Salonika fell into Turkish hands for the first time in 1387, for the second in 1391 and finally in 1430. The best lands in the plains were distributed among the Turkish chiefs and a system of feudal tenure was developed. The Christian peasants either were driven to the less fruitful regions or remained on the lands assigned to the Muslim lords, to whom they paid a *tithe*. (See SERBIA: History.)

The ethnic conditions of Macedonia were still further complicated. Large colonies of Turks were settled in the plains, while the Muslim Albanians (called Arnauts by the Turks and Shkipetars by the Serbs) spread eastward, occupying much land in western Macedonia. The Serbian element, which had been strengthened under Stephen Dushan, was weakened by the great northward emigration of 1691 and 1740. The national consciousness of Serbs and Bulgars alike suffered a heavy blow when the patriarchates of Pec or Ipek (Serbian) and of Ohrid (Bulgarian) were abolished in 1766 and 1777 respectively. From that time the spiritual control of the Christian peoples in the Balkans became vested solely in the Greek Phanar or ecumenical patriarchate of Constantinople. The Greeks continued to live in towns controlling trade, but from the 16th century onward they had to face serious competition among the Sephardic Jews, who, expelled from Spain, founded prosperous communities at Salonika and in other Macedonian towns. There were also, as centuries before, Vlachs (called Kutso-Vlachs by the Greeks and Tsintsars by the Slavs) and a few Armenians.

With the decadence of the central power in the Ottoman empire the condition of the Christian population of Macedonia worsened. The reforms of 1839 and 1856, both of which proclaimed the equality of races and religions, remained unfulfilled. In 1864 Macedonia was divided into three *vilayets* or provinces: that of Salonika; that of Monastir (Bitola), which included parts of Albania; and that of Kosovo, with the capital at Uskub (Skopje), which protruded into "Old Serbia."

The Resurgence of Bulgaria.—In the 19th century the Russian empire, in pursuance of its designs on Istanbul and the Turkish straits, presented itself in the Balkans in the guise of a liberator,

addressing itself in particular to the Bulgars. Russia started by pressing the Porte to agree to the creation of an autocephalous Orthodox Church for the Bulgarian people. After some resistance, the Porte acquiesced, hoping to strengthen its grip on the Balkans by dividing its Christian subjects. In 1870 Sultan Abdul-Aziz issued the firman creating the Bulgarian exarchate with jurisdiction over 15 dioceses: "Christian" and "Greek" were no longer synonymous in European Turkey. The ecumenical patriarch succeeded in postponing for two years the appointment of the first Bulgarian exarch and then excommunicated him and his flock as schismatics.

In 1878, after a victorious campaign, Russia compelled Turkey to recognize the independence of Bulgaria. By the treaty of San Stefano (March 3), the new Bulgarian state was given the whole of Macedonia, except Salonika and the Khalkidhiki (Chalcidice) peninsula. But Great Britain had also its protégés in the Balkans and immediately and energetically vetoed this treaty as unfair to the Greeks of Macedonia. The treaty of Berlin (July 13), to which all the great powers were signatories, created in the northern part of the Danube *vilayet*, as Bulgaria was then styled, a Bulgarian principality with Sofia as capital under the suzerainty of the sultan; in the southern part was formed an autonomous province of Eastern Rumelia, with Plovdiv as capital, under a Christian governor appointed by the Porte, with the assent of the powers. Russian-sponsored Bulgaria was thus seriously reduced in size, but the Macedonian strongholds of Hellenism remained under Turkey.

The artificial division of Bulgaria into two units did not last long; on Sept. 18, 1885, Bulgarian nationalists deposed the governor and proclaimed the union of Eastern Rumelia with Bulgaria. To the general surprise the coup succeeded, because Turkey abstained from intervening; and a Serbian attack on Bulgaria was very soon repulsed (see SERBO-BULGARIAN WAR). The Russian emperor, however, was offended because his protégé Alexander of Battenberg, first prince of Bulgaria, with the advice of Stefan Stambulov, then the speaker of the Bulgarian *sobranie*, had dared to proclaim the unification without asking for Russian help. To recover their influence in Sofia, the Russians organized a *coup d'état* on Aug. 21, 1886, which enforced Alexander's abdication. On July 7, 1887, Ferdinand of Saxe-Coburg-Gotha was elected second prince of Bulgaria. But clumsy Russian diplomacy only increased the Bulgarian people's spirit of independence. Stambulov, now premier, saw clearly that it was in Bulgaria's interest to establish friendly relations with Turkey; he was thus able to secure exequatur for Bulgarian bishops at Ohrid and Skopje in 1891 and at Veles and Nevrokop in 1894. In 1894 Ferdinand felt strong enough to dismiss Stambulov and to make his peace with Russia, but he continued to cultivate the good grace of the sultan, his suzerain. In 1898 Bulgarian prelates were appointed bishops of Bitola, Debar and Strumitsa. In 1900 Bulgaria had 785 schools in Macedonia; Serbia had only 178 and Greece 927.

Komitaji, Andartai and Chetnitsi.—The Sofia nationalists argued that the Slavs of Macedonia spoke a dialect akin to Bulgarian and therefore should be regarded as Bulgars and that all Macedonia should be incorporated into Bulgaria. The Belgrade nationalists affirmed that, as the Macedonian Slavs retained the custom of *slava* (feast of ancestors), common to all Serbs but not occurring among the Bulgars, they could not be genuine Bulgars, but were at best superficially bulgarized Serbs, whose land, it was argued, should be incorporated into a greater Serbia. The Greek nationalists maintained that the few hundred thousands of "Slavophones" whom they acknowledged to be in Macedonia were attracted by the superior Greek culture and considered themselves of Greek nationality. The Rumanians had no territorial claims in Macedonia but considered it useful to support the Vlachs, whom they called Arumanians.

The liberation of Macedonia from the Turks was desired by all non-Muslim Macedonians. To prepare it, a group of Macedo-Slavonic leaders, Dame Gruev (1871–1906), Gotse Delchev (1871–1903), Yane Sandanski (1875–1915) and others, formed a secret Internal Macedonian Revolutionary organization (Vatreshna Makedonska Revolutsionna Organizatsia or V.M.R.O.) in Salonika in Nov. 1893, which put forward a slogan of "Macedonia for the Macedonians" and the idea of a Balkan federation. After the fall

of Stambulov (1894), the Bulgarian nationalists had reason to believe that the Russian government would attempt to restore the Bulgaria of the San Stefano treaty. In March 1895 a Supreme Committee for Macedonia and Adrianople (Vrkhoven Makedonski Odrinski Komitet) was formed at Sofia; its aim was to prepare the incorporation of the whole of Macedonia and the province of Adrianople into Bulgaria. Ferdinand was not opposed to the idea of maintaining a pro-Bulgarian agitation in Macedonia and Thrace but ordered his war ministry to keep the V.M.R.O. and the Supreme committee under control. This, he thought, should be simple, because both were to be supplied with money and arms from Sofia. The first president of the Supreme committee was Traiko Kytanchev, but, as the real power was in the hands of the war ministry, the position of president was not easy and changes were frequent. From 1899 the president of the committee was Boris Sarafov (1872?-1907). His main task was to send guerrilla bands (hence the name of *komitaji* or "committeemen") into Macedonia to coerce the population into declaring itself Bulgarian and to make certain that the V.M.R.O. would follow Sofia's line.

Sofia was not the only Balkan capital from which such irredentist activity was organized in Macedonia. Athens was disconcerted by the progress of Bulgarian propaganda. The Greek religious and educational organizations were well established but fighting a defensive battle. To counteract the Bulgarian activities and also to bring about a war with Turkey, a newly formed Ethniki Etaireia was sending guerrilla bands of *andartai* into Macedonia. These succeeded in provoking the Greco-Turkish War (*q.v.*) of 1897, which ended in the complete defeat of Greece and thus benefited the Bulgarian movement. By then the Turks were sufficiently informed about the underground activities of the V.M.R.O. and of the Supremists; to counterbalance their influence the Porte inclined to favour other nationalities. Serbia, cut off from expansion in Bosnia-Hercegovina by the Austrian occupation, could look only southward. The patriotic society Narodna Odbrana ("National Defense"), controlled by the ministry of war, started sending *cheti* (companies) of underground fighters into Macedonia to encourage a pro-Serbian movement among the Macedonian Slavs, and a Serbian source mentions the names of Jovan Dovezenski, Djordje Skopljanec, Gligor Sokolovic and Jovan Babunski (Stojkovic) as the most famous *chetnitsi*. At the same time Belgrade began to agitate for the restoration of the Serbian patriarchate of Pec; a prolonged conflict with the Phanar secured only the appointment of a Serb, Msgr. Firmilian Drazic, as archbishop of Skopje in 1902. In 1905 a Rumanian bishop was appointed at Bitola. At that time there were about 40 Rumanian schools in Macedonia, including a *gymnasium* at Bitola founded in 1866 by the priest Apostol Margaritis. The Bulgars did not like this Serbian and Rumanian trespassing into a land that they considered their own; but they concentrated their efforts on combating the Greeks and the Grekomans (as they called pro-Greek Macedonian Slavs). At this time it was Lambros Koromylos, the Greek consul general at Salonika, who directed the whole secret organization of agents and bands upholding Hellenism against the Bulgars.

The terrorist activities of Bulgarian, Greek, Serbian and Turkish elements created so serious a situation in Macedonia that on Feb. 21, 1903, the Russian and Austro-Hungarian ambassadors presented identical notes to the Porte demanding the appointment of an inspector general for the three Macedonian *vilayets* and the reorganization of the *gendarmérie* with the aid of foreign officers. Sultan Abdul-Hamid II accepted the scheme, and the Sofia government, under Russian pressure, pretended to have dissolved the Supreme committee.

The V.M.R.O., however, was unreachable, and on Aug. 2 a general rising started in Macedonia, no doubt inspired by Sofia. The Supremist agents assured Gruev and Delchev that, once the insurgents had tied down a sufficient number of Turkish forces, the Bulgarian army would intervene. By the end of September, however, the rising was suppressed and the Bulgarian army, although partly mobilized, did not cross the frontier. Having achieved a complete surprise, the insurgents had some initial successes but they were eventually defeated. According to Bulgarian sources, the insurgents numbered 15,000, of whom 948 were killed as compared with

3,087 Turks killed. Turkish repression was ruthless; 105 Macedonian Slavonic villages comprising 9,830 houses were destroyed, 1,778 noncombatant Macedonian Slavs were shot and 60,953 rendered homeless. Thousands fled to Bulgaria, and their leaders complained of having been betrayed by Sofia. But Ferdinand was gratified because, he thought, the federalist tendencies of the V.M.R.O. had suffered a decisive blow so that thenceforward it would be easy to control.

On Oct. 9, 1903, the Russian and Austro-Hungarian governments submitted to the Porte a second part of their reform plan, called after the place where the emperors Nicholas II and Francis Joseph I met, the *Mürzsteg* program; this also was accepted by the sultan. Russian and Austrian civil advisers were attached to Hussein Hilmi Pasha, the Turkish inspector general of Macedonia, and an Italian general was entrusted with the reorganization of the *gendarmérie*.

In 1905 Hilmi carried out in the three *vilayets* the first census of population since the Turkish conquest, which disclosed the following results: Muslims 1,720,007; Greeks 648,962; Bulgars 557,734; Serbs 167,601; Jews and others 77,386; total 3,171,690. Under "Muslims" were included Turks and Albanians inhabiting the western part of the Bitola *vilayet* and the northwestern part of the Kosovo *vilayet*; under "Greeks," all the "Patriarchists," whether of Greek, Slavonic or Rumanian speech; under "Serbs," only those attending Serbian churches and schools, who were confined to the northern and northwestern districts of the Kosovo *vilayet*.

A Bulgarian source, dealing with Macedonia proper (*i.e.*, excluding the Albanian and "Old Serbian" *sanjaks* of the Bitola and Kosovo *vilayets*), gave the following figures for 1905: in a total population estimated at 2,258,224, there were 1,370,949 Christians, 819,235 Muslims and 68,040 Jews. From the point of view of nationalities, this source stated that there were 1,181,336 Bulgars, 499,204 Turks, 228,702 Greeks, 128,711 Albanians, 80,767 Vlachs, 68,040 Jews, 54,557 gypsies, 700 Serbs and 16,207 others (Armenians, Circassians, etc.).

In June 1908, when King Edward VII paid a visit to Nicholas II at Reval (Tallinn), an Anglo-Russian program of limited autonomy for Macedonia was prepared; but one month later the bloodless revolution of the Young Turks broke out. The internal conflicts between the various nationalities in Macedonia came temporarily to a standstill. Using this opportunity, Bulgaria proclaimed itself independent and Ferdinand took the title of tsar. The hopes of Macedonian populations that the new Turkish regime would grant them territorial autonomy were disappointed. The policy pursued by the Young Turks, who attempted to transform a multinational Ottoman empire into a national Turkish state, brought about a gradual *rapprochement* between the governments of Bulgaria, Serbia and Greece. This *rapprochement* was converted in the summer of 1912 into a military alliance, and in October the allies, declaring that promises of reform in Macedonia and elsewhere had not been fulfilled, attacked Turkey.

The Balkan Wars and World War I.—Bulgaria and Serbia concluded an agreement stipulating that Bulgaria should annex "the territory east of the Rhodope mountains and the river Struma," while Serbia was to annex the lands lying "north and west of the Sar Planina." But so great was their mutual distrust that no agreement could be reached as to the destiny of the main bulk of Macedonia. The Serbo-Bulgarian treaty of March 13, 1912, stipulated that, if autonomy for the rest of Macedonia were found to be impossible, the two states were to accept a partition along a line running roughly southwestward from Kriva Palanka through Veles to Ohrid; alternatively, the Russian emperor would be asked to arbitrate and fix the Serbo-Bulgarian frontier in Macedonia. Between Greece and Bulgaria the feud was even deeper; and no previous agreement had been reached as to the ultimate distribution of territory to be taken from Turkey. Such a situation was fraught with danger, and, after the Balkan league's victorious campaign against the Turks, the Bulgars, on June 29, 1913, suddenly turned on their allies. Defeated by both Serbs and Greeks, attacked from the rear by the Rumanians, the Bulgars had to sue for peace. (See BALKAN WARS.) By the treaty of Bucharest of Aug. 10, 1913, Macedonia was divided: Greece took the southern half of it, with a new northern frontier running from Lake Prespa through

Kajmakalan to Lake Doiran, then eastward along the Belasitsa range and the lower Mesta; Bulgaria received the Strumitsa district, with the Pirin massif; and Serbia had the remainder.

When World War I broke out in 1914, Ferdinand saw a chance of revenge and of realizing his territorial ambitions in Macedonia. Bulgaria entered the war in Oct. 1915, on the side of the Central Powers and rapidly occupied not only all Serbian Macedonia but also parts of Serbia proper. The Allies landed at Salonika to help Serbia, but only in 1918 were they able to carry through a successful offensive, which led to the Bulgarian armistice of Sept. 29, 1918. The treaty of Neuilly (Nov. 27, 1919) left the Greco-Yugoslav frontier unchanged but transferred the district of Strumitsa (Serb. Strumica) to Yugoslavia. Greek or Aegean Macedonia then had 13,361 sq.mi.; Yugoslav or Vardar Macedonia, 10,229 sq.mi.; Bulgarian or Pirin Macedonia, 2,621 sq.mi.

The 1920s and 1930s.—During the period between the outbreak of the first Balkan War and the end of World War I, certain movements of population had taken place in Macedonia; about 100,000 Turks had fled or been transported to Turkey in 1912–13; many pro-Bulgarian Macedonians had fled to Bulgaria in 1913 and many others in 1918; and in 1913 the Greeks from Melnik, Strumitsa and Bitola had withdrawn to Greek Macedonia. After the treaty of Neuilly, moreover, about 25,000 Greeks left Bulgaria and 46,878 Bulgars left the eastern half of Greek Macedonia (approximately 80,000 "Slavophones," however, preferred to remain in the western half). A much more radical exchange of population took place under the Lausanne convention (Jan. 30, 1923), after Greece's defeat in Anatolia: 375,976 Turks left Greek Macedonia and 638,253 of the 1,222,000 Greek refugees from Turkey were installed in their place.

No exchange of population took place in Yugoslav Macedonia. The Belgrade authorities considered the Macedonians as "Southern Serbs" and, to make the population thoroughly Serbian, took steps to repress pro-Bulgarian sentiments. This soon led to new tension. In 1920 the V.M.R.O. was revived and Todor Aleksandrov became its leader. It started a campaign of terrorism in Yugoslav Macedonia. When in March 1923 Aleksandr Stamboliski, the Bulgarian premier, attempted to make terms with Yugoslavia, Aleksandrov declared "irrevocable hostility" against his government. Macedonians took an active part in overthrowing Stamboliski and in his assassination (June 1923).

A movement for an autonomous province within a federal Yugoslavia was born with Pero Shandanov as its leader, but the Belgrade government gave it no support. In April 1924, in Vienna, Dimiter Vlahov, a Macedonian Communist (and a former Bulgarian civil servant), persuaded Aleksandrov to fight for an autonomous Macedonia within a Communist Balkan federation. A manifesto along these lines, signed on May 6 and published on July 15, frightened the Sofia government; and on Aug. 31, 1924, Aleksandrov was assassinated in his Pirin hiding place. Gen. Aleksandr Protogerov and Ivan Mikhailov then became the leaders of the V.M.R.O. Mikhailov organized the assassination of many federalist Macedonian leaders and eventually of Protogerov himself, in Sofia on July 7, 1928, because he opposed the policy of assassinating federalists indiscriminately.

Yugoslav security measures made V.M.R.O. activity in Macedonia more difficult; and in the 1930s, as Fascist Italy began to exploit the organization, opposition to its activity increased also among Bulgarian politicians and army officers. On May 19, 1934, when a government headed by Kimon Georgiev and Col. Damian Velchev took power in Sofia, the V.M.R.O. was dissolved, its leaders were arrested and its members disarmed. Mikhailov escaped to Turkey, whence he later went to Germany.

World War II and After.—When Yugoslavia was partitioned in 1941 by the Axis powers, Bulgaria again occupied almost all Macedonia; a few northwestern districts, however, were incorporated into Albania and some southwestern ones occupied by the Italians, while Salonika (where only 9,000 of the 50,000 Jews escaped the gas chambers) was occupied by the Germans.

On July 12, 1943, at Petrich, in Bulgarian Macedonia, Dushan Daskalov, on behalf of the Bulgarian Communist party, and Yanis Ionnidis, on behalf of the Communist party of Greece, signed

an agreement stipulating that the whole of Macedonia after the war should be an independent republic within the Balkan Communist federation. By then, however, the importance of Tito (Josip Broz) was growing inside Yugoslavia. In Tito's opinion Balkan federation should be effected under the leadership of the Communist party of Yugoslavia; and already in Feb. 1943 he had sent Svetozar Vukmanovic (General Tempo) to Skopje to organize a Macedonian section of the Yugoslav liberation movement. In 1945 Vlahov became chairman of the presidium of the Macedonian national assembly and vice-president of the federal republic of Yugoslavia, while Lazar Kulishevski became premier of the republic of Macedonia (with Skopje as capital).

Immediately after the war Tito was looking south, toward Salonika. At Skopje on Oct. 11, 1945, he said: "We shall never renounce the right of the Macedonian people to unite. There are brothers in Aegean Macedonia to whose destiny we are not indifferent." The peace treaty with Bulgaria, signed in Paris on Feb. 10, 1947, nevertheless introduced no changes in the territorial settlement in Macedonia as fixed in 1919, although the Greek government attempted to put in a claim to the Pirin area. But at that time the second Communist rising in Greece was in progress and the future of the country was in the balance. At a meeting at Bled, in Aug. 1947, between Tito and Georgi Dimitrov, the Communist premier of Bulgaria, it was agreed that, on the successful conclusion of the Greek Communist rebellion, Greek Macedonia should be incorporated into Yugoslav Macedonia, that Greek Thrace should become part of Bulgaria and that a great South-Slav federation uniting Yugoslavia and Bulgaria should be formed. In Jan. 1948, however, Moscow, already exchanging somewhat cool notes with Tito, rebuked Dimitrov for supporting such a plan; and on June 28, 1948, the breach between Tito and Moscow was made public.

In Nov. 1948 an organization of Macedonians in Bulgaria was allowed to announce that the only correct and democratic solution of the problem was a Macedonian state equal to Yugoslavia and Bulgaria; and in March 1949 the Greek rebel government (which had its seat in the Vitsi massif in Greek Macedonia) sponsored a similar plan. Tito's reply, the closing of the Greco-Yugoslav frontier (announced on July 10, 1949), contributed much to the crushing of the rebellion in Greece (September).

Yugoslavia concluded a pact of friendship with Greece on Feb. 28, 1953, and a military alliance with Greece and Turkey on Aug. 9, 1954; but after the Soviet-Yugoslav *détente* (from 1955) Tito lost interest in the military alliance and proclaimed Yugoslavia a noncommitted country. In Dec. 1961, under the pressure of the Skopje Macedonian authorities, the Yugoslav government publicly urged the Greeks to acknowledge the Macedonian minority in Greece and to give due consideration to its status and interests. The Greek government, however, maintained that no Macedonian minority existed within its frontiers and, in March 1962, suspended the agreement that it had made with Yugoslavia in 1959 to allow the easy movement of border populations across the frontier.

(K. SM.)

MACEDONTIUS (d. c. 362), bishop of Constantinople after whom are named the Macedonian heretics (*Pneumatomachoi*) who denied the uncreated nature of the Holy Spirit. Macedonius was

not himself a heresiarch; it seems that some of his followers became *Pneumatomachoi* after his death. Macedonius was a candidate for the see of Constantinople when Alexander died and Paul was elected. Paul was banished in favour of the Arianizing Eusebius of Nicomedia. On Eusebius' death, in spite of Paul's presence in the city, Macedonius was elected bishop in 342. Constantine I's attempts to banish Paul were resisted, but the rivals remained unmolested. Paul went to Rome to appeal, and appears to have been reinstated, being exiled again on the death of Constans; Macedonius returned to the see, and was again deposed c. 358. Macedonius was semi-Arian rather than Arian in belief, supporting the homoiousians as against the homoousians of Nicaea (*see* COUNCIL). On the whole the semi-Arian position was nearer to orthodoxy than has been formerly conceded. The attributing of heresy to Macedonius occurs first c. 380 in St. Jerome's translation of Eusebius' *Chronicon*. Macedonius was anathematized by Pope Damasus in 381, and in 385 Theodosius I grouped the Macedonians with other heretics in his repressive measures.

See G. Bardy in A. Vacant (ed.), *Dictionnaire de théologie catholique*, vol. ix, col. 1464-78 (1926). (A. O.)

MACEIÓ, a city and port in northeastern Brazil and capital of the state of Alagoas, about 125 mi. S.S.W. of Recife, in latitude 9° 39' 35" S., longitude 35° 44' 36" W. Population (1960) 153,305. The city stands at the foot of low bluffs, about a mile from the Atlantic ocean. The lighthouse, situated in the middle of the city, is a conspicuous landmark. Jaraguá, the port of Maceió, is practically a suburb of the city. South of the port is the shallow entrance to the Lagoa do Norte, or Lagoa Mundaú, a salt-water lake extending inland for several miles. Maceió is attractively situated in the midst of large plantations of coconut and *dendê* palms, though the broad sandy beach in front and the open sun-burned plain behind give a barren character to its surroundings. The tropical heat is moderated by the southeast trade winds, and the city is considered healthful. Maceió has rail and road connections with interior towns and with Recife and other cities to the north, but to the south both railroad and highway extend only to the São Francisco river. Domestic airlines provide regular service from the airport at Jaraguá to all major cities of Brazil. The port is protected by a reef parallel with and a half mile from the shore, behind which vessels of light draft find a fairly safe anchorage. Ocean-going ships anchor outside the reef. Exports consist principally of sugar, cotton and rum. Maceió dates from 1815 when a small settlement there was created a "villa." In 1839 it became the provincial capital and was raised to the status of a city by the provincial legislature. (R. E. P.)

MACEK, VLADIMIR (1879-1964), Croatian national leader who opposed both Serbian domination of his country and the Communist dictatorship, was born at Jastrebarsko, near Zagreb. In 1905 he became a solicitor and joined the Croatian Peasant party. In 1920 he was elected member of the Yugoslav constitutional assembly, but boycotted its work, as did other party members. In Aug. 1928, after Stjepan Radic's assassination (June 20), Macek succeeded him as leader of the Peasant party and in that capacity proposed that King Alexander should reorganize Yugoslavia on a truly federal basis by re-establishing the historical boundaries as they existed before Yugoslavia had been established. The king rejected this suggestion and introduced his dictatorship. Macek stubbornly opposed this regime and was twice imprisoned (1929-30 and 1933-34). The semidictatorial regency of Prince Paul after Alexander's assassination (1934) held parliamentary elections in 1935 and in 1938, and on both occasions Macek headed the list of candidates of all Yugoslav opposition parties. On Aug. 25, 1939, Macek negotiated with the Yugoslav government headed by Dragisa Cvetkovic an agreement which established a Croatian *banovina* (province) with its own parliament and government at Zagreb and autonomy extending to all political activities except foreign affairs, defense, transport, communications and finance. Two days later Macek joined the Yugoslav government as deputy prime minister.

On March 25, 1941, Macek reluctantly agreed to Yugoslavia's adherence to the German-Italian-Japanese pact in exchange for German guarantees. When on March 27 King Peter II took over

full royal powers and Gen. Dusan Simovic overthrew the Cvetkovic government, Macek joined the new administration. After the German-Italian aggression of April 6, 1941, he remained in Croatia, refusing the German invitation to head the Croatian puppet government. In May 1945 he left for Paris to escape from the Communists. From 1948 he lived in Washington, where he died on May 15, 1964. He published *In the Struggle for Freedom* in 1958.

(A. S. Pa.)

McENTEE, JERVIS (1828-1891), U.S. landscape painter of the Hudson River school, was born at Rondout, N.Y., July 14, 1828, and was a pupil of Frederick E. Church. He was made an associate of the National Academy of Design, New York city, in 1860, and a full academician in 1861.

In 1869 McEntee visited Europe, painting much in Italy. He excelled in pictures of autumn scenery, as in "Edge of a Wood, November" and "Yellow Autumn Woods."

McEntee died at Rondout, Jan. 27, 1891.

MACEO Y GRAJALES, ANTONIO (1845-1896), Cuban patriot and general, was born July 14, 1845, at Santiago, Cuba, of a Venezuelan father and a Dominican mother. He fought for Cuban independence throughout the Ten Years' War (1868-78), rising to the rank of commander. Much of the time between 1878 and 1895 he spent in exile in the United States, Central America and elsewhere. Soon after revolt again broke out in Cuba, Feb. 1895, Maceo returned there to assume command of all rebel forces in Oriente province. He was a daring leader and won many skillful victories over larger Spanish forces. After many narrow escapes, Maceo was killed in a skirmish at San Pedro, Dec. 7, 1896.

(R. H. Fl.)

MACERATA, the chief town of Macerata province, the Marches, Italy, and an episcopal see, is situated on a hill between the Chienti and Potenza rivers, 35 km. (22 mi.) S.S.W. of Ancona, on the Civitanova Alta-Marche-Fabriano railway line. Pop. (1961) 38,709. The town was built in the 10th and 11th centuries on the ruins of the ancient Helvia Ricina, which had been destroyed in A.D. 408 by Alaric. Noteworthy buildings include the 15th-century Loggia dei Mercanti; the neoclassic Sferisterio (sports arena); and the church of Sta. Maria delle Vergini, containing a painting by Tintoretto. The Pinacoteca Civica has a good collection of paintings. The library, with documents and incunabula, has an annexed art gallery and Museo del Risorgimento. Macerata is the seat of a university with a faculty of jurisprudence, founded in 1290, and of several learned institutes. It is the birthplace of the astronomer Francesco de Vico, the Jesuit missionary Matteo Ricci and the poet Giovanni Crescimbeni. The town has an important agricultural market for cereals and is noted for sheep and pig breeding, horticulture and floriculture. Industries include brewing, brickmaking and the manufacture of musical instruments.

The province of Macerata, with an area of 1,724 sq.km. (666 sq.mi.) and a population (1961) of 289,517, is largely agricultural, producing chiefly cereals. Cattle and sheep breeding are important in the Apennines. Camerino is the seat of a university. There are mineral waters at Sarnano, and Bolognola contains extensive ski runs. (M. T. A. N.)

MACEWEN, SIR WILLIAM (1848-1924), Scottish surgeon, was born on June 22, 1848, at Rothesay, and educated at Glasgow university. In 1892 he was made regius professor of surgery in the university. In 1922 he was president of the British Medical association. Macewen was a firm supporter of the methods of Joseph Lister, and experimented on the sterilization of instruments and dressings and the preparation of catgut for surgical use. He advanced the practice of bone grafting and became famous for his operative treatment of knock-knee. His paper on surgery of the brain and spinal cord marked him as a pioneer of modern cerebral surgery. He died on March 22, 1924.

Macewen's best-known works are *Osteotomy* (1880); *Atlas of Head Sections* (1893); *On Pyogenic Infective Disease of the Brain and Spinal Cord* (1893); *On the Growth of Bone* (1912); and "Brain Surgery," in *British Medical Journal* (1922).

MACFARREN, SIR GEORGE ALEXANDER (1813-1887), English composer and teacher, born in London, March 2, 1813. He entered the Royal Academy of Music in 1829 and be-

came professor there in 1834. He wrote four operas, *Don Quixote*, *Charles II*, *Robin Hood* and *Helvellyn*, produced in London between 1846 and 1864, oratorios, sacred works, songs and theoretical works. In 1875 he was appointed professor of music at Cambridge university and, the following year, principal of the Royal Academy of Music. He was knighted in 1883 and died in London on Oct. 31, 1887. Natalia Macfarren (1827–1916), whom he married in 1844, was an opera singer and teacher of singing.

See H. C. Bannister, *G. A. Macfarren* (1891).

McGEE, THOMAS D'ARCY (1825–1868), Irish-Canadian politician and writer, who began his career as an Irish patriot and ended as a powerful advocate of Canadian federation, was born at Carlingford, County Louth, Ire., on April 13, 1825. A prolific poet, he was of a type comparatively rare in North America, the man of letters in public life. Between 1842 and 1848 as orator and writer McGee became a strong champion of Ireland's national interests. Although he did not take up arms he was implicated in the abortive Irish rebellion of 1848 and escaped to the United States. Between 1848 and 1853 he established two newspapers there, the *New York Nation* and the *American Celt*.

McGee gradually came to advocate peaceful development for Ireland instead of the revolution urged by the extremists and in 1857 he moved to Canada. As a loyal adherent of the British connection he began an active career in Canadian public life. Elected to the legislative assembly in 1858 as the member for Montreal west, he soon distinguished himself by his powerful debating skill. He was the president of the council in the Reform administration (1862–63) and minister of agriculture in the liberal-conservative administration of 1864 and in the coalition government (1864–67). He played an active and eloquent part in the movement leading to Canadian federation. On April 7, 1868, he was shot by an assassin in Ottawa. His utterances against the Fenian invasion were believed to have been the cause of the crime, for which P. J. Whelan, a Fenian, was convicted and executed.

Among McGee's many works were *A History of the Irish Settlers in North America* (1851), *Canadian Ballads and Occasional Verses* (1858); *A Popular History of Ireland*, 2 vol. (1864); *Speeches and Addresses, Chiefly on the Subject of British American Union* (1865); and *The Poems of Thomas D'Arcy McGee*, ed. by M. A. Sadleir (1869).

MACGHILL-EATHAIN, SOMHAIRLE (SORLEY or SAMUEL MACLEAN), (1911–), Scottish Gaelic poet, an outstanding figure in the establishment of a new school of Scottish Gaelic poetry in the 20th century, was born in Raasay, Skye, on Oct. 26, 1911, and was educated at Portree and Edinburgh university.

The book on which his reputation rests is *Dàin do Eimhir agus Dàn Eile* (1943), the first section of which consists of 48 lyrics, mainly celebrating two unhappy love affairs, and largely written between 1937 and 1939, although earlier poems are incorporated in it. The series is remarkable for its emotional intensity, the richness of its imagery and its combination of the love theme with a wide range of literary, political and social references. The poetical background is radical, with strong leanings to a communism tempered by Scottish nationalism. In the second part of the book Maclean renounces his love for Eimhir, and a mood of disillusion, accompanied by intellectual frustration, appears.

Maclean's metrical technique is traditional, his main innovations being in subject matter. His poetry was a reaction against 19th-century Gaelic verse. He made a conscious attempt to widen horizons, by wide-ranging references to Russia, to the Spanish Civil War, to characters in French romance and early Irish literature. His reading and thought were brought to a fruitful connection with his experience and were used to illumine and add new dimensions to that experience.

BIBLIOGRAPHY.—*17 Poems for 6d* (1940), 5 poems in *Modern Scottish Poetry, 1920–1945*, ed. by J. M. Lindsay (1946); *Honour'd Shade*, ed. by Norman MacCaig (1959). See also Iain Smith, "Modern Scottish Gaelic Poetry," *Scottish Gaelic Studies*, vol. vii, pp. 199–202 (1955).

(D. S. T.)

McGILLIVRAY, ALEXANDER (c. 1759–1793), an American trader of mixed blood, chief of the Creek tribe, who played an important role in the history of the southwestern colonial frontier during and after the American Revolution. His father, Lachlan McGillivray, was a Scottish trader and politician in the colony of Georgia; his mother is thought to have been Sehoy Marchand, a half-breed French-Creek woman. McGillivray spent his childhood on his father's plantation and trading post in what is now the state of Alabama. In early youth he was sent to Charleston, S.C., and Savannah, Ga., to learn business methods and to acquire some polish. During the American Revolution he was pro-British in politics and became a powerful personal factor for the British cause in the southwest, inciting the Indians to attack the settlers. As a trader he was thrown into frequent contact with the famous trading firm of Pantón, Leslie and Company. From the end of the Revolutionary War in 1783 to his death in 1793 he played important roles in dealing on behalf of the Indians with the U.S. and Spanish governments. Both nations paid him tribute, and the United States made him a brigadier general. McGillivray's main concern was the welfare of his Indian wards and the rich trade that went on about him.

Some authorities claim that this famous leader was one of the most cultivated Indians in North America. His interests ran more to diplomacy than to military affairs. Though he was a brigadier general he could never be called a warrior. The territory where he lived was a haven for speculators and adventurers and required shrewd management and ruthless dealings to survive. That McGillivray's leadership was capable was demonstrated by his influence over so large a number of Indians. As a plantation owner he pioneered in Alabama with a pattern of life that was later to characterize the great black belt of that state.

See John W. Caughey, *McGillivray of the Creeks* (1938).

(T. D. C.)

McGILL UNIVERSITY, a private, nonsectarian coeducational institution in Montreal, Can., was chartered in 1821 as McGill University college; instruction began in 1829. See MONTREAL.

McGUFFEY, WILLIAM HOLMES (1800–1873), U.S. educator, who is remembered chiefly for his elementary school readers, was born in western Pennsylvania on Sept. 23, 1800, of Scotch-Irish parents. In 1802 they moved into the forests of the Ohio Territory four miles north of the present city of Youngstown. With little home or school instruction, McGuffey mastered the school arts and began teaching in the subscription rural schools of Ohio when he was 13 years of age. During spare time and vacations, through his 11 years of teaching in Ohio and Kentucky, he continued his own education intermittently under private tutors, in Greensburg academy and in Washington college, receiving his A.B. degree with honours in 1826.

McGuffey went to Miami university, Oxford, O., as instructor in ancient languages in Nov. 1825, became professor of languages in 1826, and during 11 years there took great interest in public education. He assisted the teachers of the elementary schools of the community and established in his own home a model school of the neighbourhood children.

In 1835 he contracted with Truman and Smith, publishers, of Cincinnati to compile four school readers, the first and second of which were published in 1836 and the third and fourth in 1837. A fifth was published in 1844, a spelling book by McGuffey's brother, Alexander Hamilton McGuffey, came out in 1846, and a sixth reader was added in 1857. These textbooks became virtually the universal readers in the expanding common schools of the great empire of the Mississippi and the south. They went through many editions and sold 122,000,000 copies.

From 1836 to 1839 McGuffey was president of Cincinnati college and from 1839 to 1843 president of Ohio university, Athens. He was one of the three founders of the common school system of Ohio. In 1845 he was elected to the chair of mental and moral philosophy in the University of Virginia, Charlottesville, which position he eminently filled until his death on May 4, 1873.

MACH, ERNST (1838–1916), Austrian physicist and philosopher, whose work, both in physics and in philosophy, had a great influence on 20th-century thought, was born on Feb. 18, 1838, at

Turas in Moravia and educated in Vienna. He was professor of physics at Graz from 1864 to 1867 and at Prague from 1867 to 1895, and professor of inductive philosophy at Vienna from 1895 to 1901. He was made a member of the Austrian house of peers in 1901 and died at Haar, near Munich, on Feb. 19, 1916.

Mach was a thoroughgoing positivist and took the view, which most scientists now share, that no statement is admissible in natural science unless it is empirically verifiable. His criteria of verifiability were, however, exceptionally rigorous: they led him not only to reject such metaphysical conceptions as that of the ether and that of absolute space and time but also to oppose the introduction of atoms and molecules into physical theory. Nevertheless it was his criticism along these lines of Sir Isaac Newton's system that made the way clear for Albert Einstein's theory of relativity. As a positivist, he regarded scientific laws as purely descriptive; and he held that the choice between alternative hypotheses covering the same facts was to be made on the grounds of economy.

Mach's philosophical position was phenomenistic. He maintained that all empirical statements, including those that occur in scientific theories, were in the end reducible to statements about sensations. He tried to lay the basis for the phenomenalist reduction in his book *Analysis of Sensations*, but neither he nor any other philosopher has yet succeeded in carrying it through. Though it would be incorrect to call him an idealist, Mach's views have a certain resemblance to those of Berkeley, and for this reason he was sharply attacked by Lenin in *Materialism and Empirio-Criticism*. His philosophy survived to become one of the sources of inspiration of the Vienna circle of the 1920s (see LOGICAL POSITIVISM), the members of which mostly came to reject Mach's phenomenalism but continued to support him in his hostility to metaphysics, in his positivist conception of scientific method and in his insistence upon the unity of science.

Mach's name is popularly associated with the Mach number (*q.v.*), which expresses the air speed of an aircraft in terms of its relation to the local speed of sound.

Mach's works include: *Die Mechanik in ihrer Entwicklung historisch-kritisch dargestellt* (1883; rev. ed., 1908; Eng. trans. by T. J. McCormack, *The Science of Mechanics*, 4th ed., 1919); *Beiträge zur Analyse der Empfindungen* (1886; 5th ed., *Die Analyse der Empfindungen und das Verhältnis des Physischen zum Psychischen*, 1906; Eng. trans. by C. M. Williams, *Contributions to the Analysis of Sensations*, 1897); *Leitfaden der Physik für Studierende* (1881), in collaboration with others; *Populärwissenschaftliche Vorlesungen* (1896; 3rd ed., 1903); *Die Prinzipien der Wärmelehre* (1896); *Erkenntnis und Irrtum* (1905; Fr. trans. by M. Dufour, *La Connaissance et l'erreur*, 1908). (Ad. J. A.; X.)

MÁCHA, KAREL HYNEK (1810–1836) Czech romantic poet of great power and individuality. Born at Prague on Nov. 16, 1810, of poor parents, Mácha was influenced as a student by the Czech national revival and by English and Polish romantic literature. Other sources of inspiration were his wanderings amid ruined castles in the Bohemian countryside and a journey to northern Italy (1834). In 1836 he took up a legal post in Litoměřice but died there, of pneumonia, on Nov. 5, 1836.

After schoolboy attempts in German he began to write poems, sketches and novels in Czech. Practically all his prose works remained unfinished, but their style shows a mastery not previously attained by writers in the newly revived Czech literary language. His lyrics express a characteristic but highly individual romantic pessimism. His best work is the lyrical epic *Máj* ("May"; 1836). Strongly Byronic in subject, this poem is yet personal in treatment and style, and stands comparison with the work of such Slavonic contemporaries as Adam Mickiewicz and Lermontov. Coldly received at the time, it has exercised an almost magical fascination on poets and critics of the 20th century. The subtle melody and rhythms of Mácha's verse defied the efforts of his numerous translators. His letters and diaries, *Dílo Karla Hynka Máchy*, edited by K. Janský, (3 vol., 1948–50), in vivid colloquial prose, are an essential supplement and background to his poetry. (R. Av.)

MACHADO, BERNARDINO LUÍS (1851–1944), Portuguese statesman, president of Portugal from Aug. 1915 to Dec.

1917 and from Dec. 1925 to May 1926, was born in Rio de Janeiro on March 28, 1851, and educated in Portugal. He received the doctorate from Coimbra university in 1876 and became a full professor there in 1879. He was elected twice to the chamber of peers as representative of the university (1890, 1894). He served as grand master of Portuguese Masonry. His parliamentary career was marked by his concern for public education. As minister of public works (1893), he created the first labour court in Portugal. Later, upon his return to Coimbra, he became president of the Instituto de Coimbra. In 1902, after espousing republicanism, he was elected president of the governing board of the republican party. He resigned his professorship as an aftermath of the national student strike (1907). With the overthrow of the monarchy (1910), he served as minister of foreign affairs (1910–11); deputy to the constituent assembly and senator (1911); and minister (later ambassador) to Brazil (1912). For the second half of 1914 he was prime minister and minister of the interior, when, under his guidance, Portugal committed itself to participation in military operations on the side of Great Britain in World War I. He was elected president on Aug. 6, 1915, but was overthrown by the revolution of Dec. 8, 1917. He became president again on Dec. 11, 1925, but was once more deposed (May 28, 1926). The revolution which brought António de Oliveira Salazar to power ultimately sent Machado into exile. With the invasion of France (1940), he was allowed to return home. He died at Oporto on April 29, 1944.

See António Machado, *Bernardino Machado, memórias* (1945); Ramos de Almeida, *Bernardino Machado* (1951). (M. Ca.)

MACHADO Y MORALES, GERARDO (1871–1939), fifth president of Cuba and considered one of its major dictators, was born at Camajuani, Santa Clara province, Sept. 29, 1871. He fought valiantly in the war for independence (1895–98) and rose to the rank of brigadier general. After the war he engaged in farming and business but retained a strong interest in politics. By 1920 he had become leader of the Liberal party.

Machado was overwhelmingly elected president in 1924. He was popular at first, but declining sugar prices brought economic depression to Cuba in 1925 and Machado had to begin a vast program of public works to counteract it. Construction under this program of the very costly Central highway and the Capitol later led to charges of graft against his government.

By 1927 Machado had gained control of all three Cuban political parties. His regime then rapidly became more dictatorial. Rising opposition in 1933, climaxed by the defection of the army, forced him out of office and into exile on Aug. 12. He died at Miami Beach, Fla., on March 29, 1939. (R. H. Fr.)

MACHADO Y RUIZ, ANTONIO (1875–1939), Spanish poet, who gained a high posthumous reputation in the "committed" literature of the period after World War II, was born in Seville on July 26, 1875. Most of his childhood was spent in Madrid where he was educated at the liberal Institución Libre de Enseñanza. In 1899 and 1902 he visited Paris and in 1907 he took the decisive step of his life when he became French master at the Instituto de Soria. There he married the 15-year-old Leonor Izquierdo Cuevas, who died only three years later in 1912. Subsequently Machado taught in Baeza, Segovia and Madrid. A staunch supporter of the republic during the Civil War, he crossed the French frontier when it collapsed at the beginning of 1939 and died at Collioure, Pyrénées-Orientales, on Feb. 22, 1939.

His early poems, *Soledades* (1903) and *Soledades, galerías y otros poemas* (1907), are concerned largely with evoking memories and dreams and with the subjective identification of the poet with natural phenomena, especially the sunset. Machado created with characteristically slow persistence, an austere, "nonpoetic" style and a series of fixed images to describe the "galleries" of his mind. In his groping spiritual quest for significance in life he characterized himself as "a poor man wandering in a dream, always searching for God among the mists."

In Soria Machado turned away from pure introspection, but infused into the considerable topographical precision of his descriptive poems of the arid Castilian *meseta* (contained in *Compos de Castilla*, 1912) his deep personal involvement with the landscape and people. The loving, yet critical, attitude he displays toward

Castile shows his affiliations with the "Generation of '98." Under the influence of Henri Bergson, Machado now saw poetry as essentially a reflection of the passing of time; his verse makes careful use of tense, adverbs of time and assonance, and avoids cerebral imagery and defining adjectives. His wife's death produced a few moving poems, but henceforth his poetry became more fragmentary and more philosophical. He invented the writings of two apocryphal philosophers," Juan de Mairena and Abel Martín, through whom he expressed his profound existentialist views in a deceptively disjointed form. Machado was admired for his simple modesty, his concern with authenticity and his unhurried, thoughtful dedication to poetry.

MACHADO Y RUIZ, MANUEL (1874–1947), Spanish poet of a delicate technique and decadent refinement, strongly influenced by Paul Verlaine and the *modernismo* movement of Rubén Darío (*q.v.*), was born in Seville on Aug. 29, 1874. His main merit lies in the light sensuous verse contained in *Alma* (1902), *Caprichos* (1905) and *El mal poema* (1909) in which he evokes either *fin de siècle* Paris or Moorish Andalusia; he was not, however, devoid of deeper concerns which link him with the "Generation of '98" and his brother Antonio (*q.v.*). He was influenced by popular verse and song and also wrote polished sonnets inspired by famous paintings. In collaboration with his brother he wrote some good poetic plays, the most successful being *La Lola se va a los puertos* (1929). Machado died in Madrid on Jan. 19, 1947.

MACHAULT D'ARNOUVILLE, JEAN BAPTISTE

(1701–1794), French statesman notable for his attempt at fiscal reform under Louis XV, was born in Paris on Dec. 13, 1701, of a distinguished family of lawyers. He served as intendant of Hainaut before being appointed controller general of finances in Dec. 1745, during the War of the Austrian Succession. Having had to resort to the usual expedient of borrowing in order to finance the war, he determined to institute a regular sinking fund for the redemption of the large public debt. For this, in May 1749, he introduced a 5% tax or *vingtième* on all revenue from land, offices or industry. Based on the principle of complete fiscal equality, this levy was intended to be permanent and was to be imposed on the privileged *pays d'états* (which voted their own taxes), as well as on the *pays d'élection*. The resistance of the *parlements* and the provincial estates was overcome, but the violent opposition of the assembly of the clergy, supported by the Ultramontane party at court, brought about the failure of Machault's proposals and the continued exemption of the privileged orders from the *vingtième*. Transferred to the ministry of marine in July 1754, Machault (who was also keeper of the seals from 1750) was dismissed in Feb. 1757, during the negotiation of the Franco-Austrian offensive alliance at the opening of the Seven Years' War; and no further effort was made before 1787 to subject the privileged orders to direct taxation. After the outbreak of the Revolution, Machault was arrested as a suspect during the Terror, and he died in prison in Paris on July 13, 1794. See *France: History*.

See M. Marion, *Machault d'Arnouville* (1891). (A. Gn.)

MACHAUT, GUILLAUME DE (c. 1300–1377), French poet and musician, greatly admired by contemporaries as a master of French versification, both in the lyric and in longer verse forms such as the *dit* and *roman*. Born at Machaut (to use the old spelling) in the Ardennes, c. 1300, in 1323 he entered the service of John of Luxembourg, king of Bohemia, as chaplain and secretary. He accompanied him on his wars and was rewarded, in 1337, with a canonry at Reims. After the king's death at the battle of Crécy (1346), he found another protector in Bonne of Luxembourg, wife of the future king John II of France, and (1349) in

Charles II, called the Bad, king of Navarre. From this time on, Machaut was honoured and patronized by kings and princes at his chosen residence in Reims, where he died in 1377.

In his longer poems, Guillaume did not go beyond the themes and genres already widely employed in his time. The *Dit dou Vergier* once again takes the reader to the Garden of Love already sung by Guillaume de Lorris in the *Roman de la Rose* (*q.v.*). Both the *Remède de fortune* and the *Confort d'Ami* are indebted to Jean de Meun (*q.v.*) and Boethius: the latter is an attempt to sustain the courage of Charles II when accused of conspiracy and imprisoned by King John. In the *Jugement du roi de Navarre* (1348), which debates a casuistic problem of love, it is the wheel of fortune which turns again. When Guillaume sings the life and deeds of Pierre de Lusignan, king of Cyprus, in the *Prise d'Alexandrie* (c. 1370), he becomes flat and tedious. Of all this part of his work, only the *Voir Dit* is considered of permanent interest. It relates how a young girl of high rank falls in love with him solely on the strength of his fame and creative accomplishment, but the difference in age is too great and the idyll ends in mutual disappointment; true or false, the story holds the attention by its sincerity. The two main protagonists exchange letters and poems; some of the verses are set to music, and indeed Machaut's beloved explicitly asks for them to be notated.

It is in fact more to his skill as a lyric poet and as a composer that Guillaume owes his reputation. He was the last great poet in France to think of the lyric and its musical setting as a single entity. As a master of the "second rhetoric," namely poetry, he composed a considerable number of *ballades*, *chants royaux*, *lais*, *rondeaux* and *virelais*. Certainly they are based on the old theme of *amour courtois* which Guillaume takes over and reworks, but their form and verbal music is often perfectly achieved. A *rondeau* or a *ballade* is written with a wit that makes a jewel out of nothing; and if there is little poetry in the romantic sense there is an abundance of charming, exquisite and lively poems, the product of an ingenious and quiet fancy.

There is equal skill, but more originality, in his musical compositions. The Mass Ordinary for four voices, which includes the *Ite missa est*, competes with the three-part Mass preserved at Tournai for the title of the earliest complete polyphonic Mass. Certainly the Machaut work is far superior in artistic quality to the Tournai Mass; it employs the characteristic 14th-century motet technique of isorhythm (*q.v.*) in *Kyrie*, *Sanctus*, *Agnus* and *Ite*, while the *Gloria* and *Credo* proceed in an ornamented note-against-note style. The *Hoquetus David* is also isorhythmic, and there seems to be some justification for the idea that this work forms a conclusion to the organum *Alleluia Nativitas* of Pérotin (*q.v.*), although written over 100 years later; at least the *melisma David* concludes the plainsong in question.

Of his 23 three- and four-part motets, 17 are in French and thus form a continuation to the 13th-century motet repertory, though the technique of isorhythm is new and cannot date from much before 1316: it is employed in all but three of Machaut's motets. The 19 *lais* are representatives of a complicated lyric genre usually set to music as an unaccompanied vocal solo. Machaut has left two three-part canonic *lais* and one in normal two-part harmony. Of 33 *virelais*, 25 are monodic, 7 have an additional accompanying part for an instrument and 1 has two such parts. The latter is typical of the accompanied solo song which became so popular in the 14th century, and which Machaut may have invented to replace the polytextual motet. At all events his 42 *ballades* and 21 *rondeaux* are best represented in the sources, which reveal that Machaut was esteemed, not only in France, but also in Italy, Spain and much of the rest of Europe.

MACHEN, JOHN GRESHAM (1881–1937), U.S. Presbyterian theologian and churchman, one of the most eloquent spokesmen for the conservative position in the theological controversies of the 1920s and 1930s, was born at Baltimore, Md., on July 28, 1881. Educated at Johns Hopkins and Princeton universities, Princeton Theological seminary and the Universities of Marburg and Göttingen, he taught at Princeton seminary from 1906 until its reorganization in 1929. Thereupon he left to help found Westminster Theological seminary in Philadelphia, where he served as professor of New Testament until his death on Jan. 1, 1937.

Machen's leading contribution to the conservative cause in the Fundamentalist-Modernist controversy was perhaps his book *Christianity and Liberalism* (1923), which contended that theological liberalism was not really Christian in the biblical and historic sense.

Machen's most scholarly books were *The Origin of Paul's Religion* (1921) and *The Virgin Birth of Christ* (1930; 2nd ed., 1932). His publications also included numerous pamphlets and articles, in addition to several other books, many of a popular nature. Refusing to resign from the Independent Board for Presbyterian Foreign Missions on the ground that the mandate of the general assembly of the Presbyterian Church, U.S.A., ordering its members to do so was unconstitutional, Machen was suspended from the ministry. When his appeal was not sustained, he left in 1936 to join in forming the Presbyterian Church in America, later known as the Orthodox Presbyterian Church.

Machen also enjoyed a world-wide reputation as a Greek scholar and learned Christian apologist. His theological position, he was wont to emphasize, was not fundamentalist, but the Reformed Faith of the Westminster Confession of Faith. See also FUNDAMENTALISM; PRESBYTERIANISM.

See autobiographical sketch in V. Ferm (ed.), *Contemporary American Theology* (1932); Ned B. Stonehouse, *J. Gresham Machen: a Biographical Memoir* (1954). (N. B. S.)

MACHIAVELLI, NICCOLÒ (1469–1527), Italian statesman and writer, a patriot and a thinker of genius whose acute understanding of contemporary politics and profound insight into human nature produced masterpieces that have too often been misjudged as immoral or cynical, was born in Florence on May 3, 1469. His family (about whose descent from the ancient lords of Montespertoli in Valdipesa there is some doubt) had from the 13th century onward been counted among the principal houses of the city, holding on occasion the most important offices and rich in worldly goods. His father, Bernardo Machiavelli (1428–1509), a doctor of laws, was however among the poorest members of the family; he lived frugally, administering his little property of Sant'Andrea, near San Casciano, and supplementing his meagre income from it with small earnings from the restricted and almost clandestine exercise of his profession, since he was debarred from any public office as an insolvent debtor of the commune of Florence. Niccolò was to write later that he had "learnt to do without before he learnt to enjoy"; and this poverty may have been the reason why he did not have the education suited to his ability. In the years when young Florentines crowded to the lectures of Politian, Machiavelli never embarked on the study of Greek. His father's *Ricordi* (memoirs) show him working at Latin under obscure teachers; he learned more by himself in the books which were the only luxury of his home than he did at school. This kind of education saved him from the faults and excesses of humanist erudition and preserved the originality of his thought and the unequalled force of his style, which is elevated and popular at the same time.

Public Life.—In 1498, after the changes in the Florentine government following the death of Savonarola and the triumph of the opposing faction, Niccolò Machiavelli was made head of the second chancery (*cancelleria*) at the early age of 29. He was then completely unknown; the tradition of his having an apprenticeship in the lower grades of the chancery from 1494 onward is not confirmed by documentary evidence, and his own statements tend to disprove it. The office to which he was appointed, though not comparable in power with that of first chancellor, was an important one. Originally it dealt only with internal affairs of the

republic, but it was later made one for practical purposes with the secretariat of the Ten (*i Dieci*). Machiavelli was, moreover, secretary to the magistracy which, in the name of the *Signoria* and under its authority, directed foreign affairs and defense. The chancellors were often entrusted with diplomatic missions to Italian and foreign courts when it was not desirable to send ambassadors because time was short or for some other reason. Machiavelli's first important mission was to the French court in 1500. Five months spent beyond the Alps enriched his experience, introducing to his eager mind another people and other customs, a nation strong with its own arms and united under the rule of a single prince.

On his return to Florence, Machiavelli found much to do, as the republic was on the verge of being ruined by the ambitions of Cesare Borgia (*q.v.*). As well as dictating letters in the chancery, Machiavelli undertook missions whenever the need arose; he was always ready to ride off and to face danger and hardship, being fonder of action than of words. His short work *Del modo di trattare i sudditi della Valdichiana ribellati* ("On the Way to Deal with the Rebel Subjects of the Val di Chiana") belongs to this period. In it the fundamental principle of a new doctrine is enunciated for the first time: "The world has always been inhabited by human beings who have always had the same passions." He was sent twice to Cesare Borgia; and during the second embassy (Oct. 1502–Jan. 1503) he was a witness of the bloody vengeance taken by Cesare on his mutinous captains at Senigallia, of which he wrote a famous account, *Del modo tenuto dal Duca Valentino nell'ammazzare Vitellozzo . . .* ("On the Manner adopted by the Duke Valentino to Kill Vitellozzo . . ."). That strong sinister prince caught the imagination of the Florentine statesman with his natural bent for abstraction and theory. Implacable, resolute, ferocious and cunning, Cesare Borgia had conquered a dominion for himself in a few months; and Machiavelli adapted Cesare's qualities and methods to his own ideal of a "new prince" who would provide a desperate remedy for the desperate ills of Italy. It is clear that this was a case of idealization and that his admiration for the prince did not go hand in hand with admiration for the man. In 1503, when Pope Alexander VI died and his successor, Pius III, too died shortly afterward, Machiavelli was sent to Rome for the duration of the conclave which elected Julius II. There, with ever-increasing scorn, he witnessed the inglorious decline of his hero and finally celebrated Cesare's imprisonment "which he deserved as a rebel against Christ."

In Florence meanwhile Piero Soderini had been elected gonfalonier for life, and Machiavelli was immediately able to win his favour and became his righthand man. This remarkable influence over the head of state encouraged him to realize his military ideas. For centuries the states of Italy had used mercenary troops in their wars, and Machiavelli had seen in practice their lack of discipline, their faithlessness and their unbearable arrogance. Inspired both by the military enterprises of ancient Rome and by his own observations in France (where he went on a second mission early in 1504) and in Romagna (where Cesare Borgia had replaced mercenaries with levies from his own territory), Machiavelli ardently pursued the idea of giving the Florentine state a militia of its own, recruited from the peoples under its control. Age-old prejudices had to be overcome, as well as the reluctance of suspicious townsmen to arm men from the country districts around. Having set to work immediately after his return from the Roman legation, he succeeded in persuading the gonfalonier to risk an experiment and then to have a law passed in order to establish a militia (1505). His first *Decennale* (a short poem in *tersa rima* somewhat prosaic like the rest of his verses) ends with a call to arms. In 1506, as the importance of the new militia increased, the council of the Nine (*i Nove*) was created to control it, and Machiavelli was made secretary of this body also. To get the law on the militia passed, he had also written a *Discorso dell'ordinare lo stato di Firenze alle armi* ("Discourse on Arming the State of Florence") which is lucid, closely argued and vigorous. The territory of the republic was divided into districts, and Machiavelli himself went out to see to the levies and to carry out inspections, alternating these military tasks with those of the

chancery and with a further mission (1506) to Julius II, whose armies, moving up to free the States of the Church from their usurpers, entered Bologna in triumph.

In Dec. 1507 the Holy Roman emperor Maximilian I was preparing an invasion of Italy from Germany. The gonfalonier, who did not trust his own ambassador at the imperial court, accordingly sent Machiavelli on another journey beyond the Alps. On the outward journey Machiavelli passed through Switzerland, and three days spent in that country were enough for him to produce some brief but acute observations on it. He did the same, at greater length, for Germany, composing on the day after his return to Florence, June 17, 1508, a *Rapporto delle cose dell'Allemagna* ("Report on the State of Germany"). In this work, compiled in the course of his official duties, and likewise in the literary version made four years later under the title *Ritratto delle cose della Magna* ("Portrait . . ."), he was able to pick out with great acumen the reasons both for the strength of the German nation and for its political weaknesses. Yet all his official reports, though marvelously intuitive, are marred by a tendency to theorize; they are bold syntheses, not complete and accurate sources of information.

On his return from Germany, as the Florentines were showing new strength in an effort to recapture Pisa, Machiavelli was able to try out the militia that he had created. He went to command his troops at the front and put all his usual enthusiasm into the task: when the Ten begged him to remain at headquarters, he answered that they must let him be with his soldiers, since behind the lines he would die of melancholy. Such was the patriotism and passion of a man who has been represented as skeptical, cautious and cynical. Pisa capitulated on June 8, 1509, and Machiavelli with his militia had no small share in this success for Florence.

After a mission to Mantua in connection with yet another ill-fated invasion by Maximilian, Machiavelli had to go again to France in July 1510 to persuade Florence's ally Louis XII either to make peace with Julius II or at least not to drag Florence into a war that would bring the republic to certain, swift and useless ruin, whereas a neutral Florence could be very useful to the French. The French, however, "who knew nothing about statecraft," were not influenced by what Machiavelli had to tell them. From this mission, which resulted in the *Ritratto delle cose della Francia*, he returned in Oct. 1510, convinced that there would be a major war between the French king and the pope and that the Florentines would be involved. All his efforts now were to arm his country. As he carried out his military duties and those of the chancery, he was continually traveling about. At the end of the summer of 1511 he went to France for the fourth time, to persuade Louis XII to remove the schismatic council that he was sponsoring in Pisa, since this had brought on the Florentines the rage of Julius II. As soon as he was back from France, Machiavelli himself went to remove this council and did so without much ceremony. For the free republic, however, the last hour had already come: the army of the pope's Holy League was already on its way to punish Florence. The gonfalonier Soderini was deposed, and the Medici returned as masters of the city (1512). Machiavelli lost his position and was forbidden to enter the Palazzo della Signoria.

Machiavelli's misfortunes were not at an end. Pietropaolo Boscoli's ill-conceived conspiracy was uncovered at the beginning of 1513, and Machiavelli, already an object of suspicion to the new government, was accused of complicity. Thrown into prison, he maintained his innocence even under tortures which often persuaded the innocent to declare themselves guilty. His name, however, was on a list taken from the conspirators (perhaps merely a list of people attached to the old regime); and finally, though he was released from prison, restrictions were put on his freedom of residence. In the meantime Julius II had died, and Giovanni de' Medici had become pope under the name of Leo X. Machiavelli composed for the celebrations on that occasion a pious *Canto degli Spiriti beati* ("Song of the Blessed Spirits"). He sought in vain to get into the good graces of the Medici through the intercession of Francesco Vettori, his old colleague in the German legation and now Florentine ambassador to a Florentine pope; but his brilliant letters to Vettori were powerless to stir that selfish and opportunist friend.

Hounded by poverty and unhappiness, Machiavelli sought refuge in the little property at Sant'Andrea inherited from his father. There he employed his leisure in writing, between spring and autumn 1513, his two most famous works, *Il Principe* ("The Prince") and a large part of the *Discorsi sopra la prima Deca di Livio* ("Discourses on the First Decade of Livy"). In a letter to Vettori, which is one of the most remarkable in any language, he describes his life in the country with its violent contrasts, its mixture of plebeian coarseness and dreams of greatness. Machiavelli's great hope was that the *Principe*, dedicated to Lorenzo between 1515 and 1516, would obtain from the Medici an office to support his family and satisfy his love of action; but in vain. Full of bitterness, he then dedicated the *Discorsi* (of which he had been giving public readings in the Oricellari gardens) not to a prince but to two private citizens. Of this period also are the mediocre poem *L'Asino* (1517) and the marvelous comedy first entitled *Commedia di Callimaco e Lucrezia*, later *Mandragola* (1518). It may be that other minor works such as the amusing tale *Il demonio che prese moglie* ("The Demon who Took a Wife"; now called the *Novella di Belfagor*) and the *Dialogo intorno alla lingua* ("Dialogue on Language") belong to these same years in which, disillusioned, he abandoned political writings for the consolations of literature.

Machiavelli's hopes were raised when, on the death of Duke Lorenzo, the cardinal Giulio de' Medici came to govern Florence. He was presented to the cardinal by Lorenzo Strozzi, to whom in gratitude he dedicated the dialogue *Dell'arte della guerra* ("On the Art of War"; 1520). In this, in the *Discorsi* and in the *Principe*, his study of classical authors was combined with his experience of modern affairs; i.e., his recent military adventures. The first employment given him by the cardinal was to go to Lucca on a matter of small importance. On that occasion he wrote his *Vita di Castruccio Castracani*, a kind of romanticized biography of the Luccan condottiere in which he idealized, as he had done with Borgia, his myth of a "new prince." This short work is only a historical sketch for a much larger work (in a contemporary document it is called a "modello di storia"). The cardinal agreed to have Machiavelli elected official historiographer of the republic, a post to which he was appointed by the Studio or University of Florence in Nov. 1520 with a salary of 57 gold florins a year, later increased to 100. The university's terms allowed for Machiavelli's also being employed in other ways. In the meantime he was to compose for the Medici pope Leo X a *Discorso* on the organization of the government of Florence after the death of Duke Lorenzo, the last legitimate lay descendant of the Medici; in this he boldly advised the pope to restore the city's ancient liberties. Shortly after, in May 1521, he was sent to the Franciscan chapter at Carpi. The commission was an insignificant one and even slightly absurd; but it provided the occasion for Machiavelli's forming with Francesco Guicciardini (q.v.), governor of nearby Modena, a friendship that was to have a great importance for Italian literature.

After Pope Leo X's death (Dec. 1521) the cardinal Giulio de' Medici, who remained sole master of Florence, was more than ever inclined to reform its government. He sought the advice of Machiavelli, who simply furnished up the *Discorso* composed for Leo X. Pope Adrian VI then died (Sept. 1523) and Giulio de' Medici was himself elected pope, taking the name of Clement VII. Machiavelli now worked with more enthusiasm at the *Storia fiorentina*, his official history of Florence; in June 1525 he was able to present the pope with eight books and received in return 120 florins and encouragement to continue. Early in the same year he had written the *Clizia*, a free imitation of the *Casina* of Plautus, which he produced within a few days for a festival. In this comedy he probably intended to satirize himself and his affair with Barbara, a singer with whom he was infatuated.

In April 1526 Machiavelli was elected secretary of the *Cinque provveditori alle mura*, a five-man body lately constituted to superintend the fortifications. Next, the pope having formed the League of Cognac against the Holy Roman emperor Charles V, Machiavelli went with the army to join Guicciardini, the pope's lieutenant, with whom he remained almost continuously until the

sack of Rome by the emperor's forces brought the war to an end (May 1527). Florence having regained its freedom by casting the Medici off, Machiavelli on his return hoped to be restored to his old post in the chancery; but the little favours which the Medici had so meagrely doled out to him caused the supporters of the free republic to forget the love that he had always had for his native city and for freedom. It was the last of his disappointments and the greatest. Machiavelli fell ill and died, with the comforts of religion, on June 21, 1527, at the age of 58.

Machiavelli's life thus fell into very nearly proportionate phases: midway, at 29, he was given the chancery (1498); having devoted the third quarter of his life entirely and exclusively to public affairs, he was dismissed at the end of it (1513); then the first half of the last quarter was enough for him to write all the major works on which his fame rests (the *Principe*, the *Discorsi*, *Mandragola* and the *Arte della guerra*); and the last eighth of his life (1521-27) was spent in writing the *Storia fiorentina* and a few minor works.

Character.—Machiavelli was of medium height, thin, with a bony face, a high forehead, black hair, piercing eyes and thin lips compressed in an enigmatic smile. He was an upright man, a good citizen and a good father. He was not by any means a faithful husband, but lived in affectionate harmony with his wife Marietta Corsini (whom he had married in the latter part of 1501) and had five children by her. As he said in a letter, he loved his native city "more than his own soul"; and even in his devotion to the state he must often have written "state" while thinking "native land."

Out of devilment and a desire to shock his contemporaries Machiavelli liked to appear more wicked than he was. This, together with certain blunt maxims in his works, gave him a reputation for immorality. In fact those maxims were purely theoretical abstractions of an art itself not always based on moral scruples, least of all in Machiavelli's own time; but their bold, lapidary style made it easy to detach them from their context and to ignore the purpose that had inspired and the needs which had conditioned them. The maxims thus became a target for attacks by the Catholic Counter-Reformation; and the word "Machiavellianism" was coined as a term of opprobrium by the French, out of hatred for all things Italian, during the rule of Catherine de Médicis. On the other hand Machiavelli was an innovator and, as such, was inclined to give extreme form to his utterances. He himself in the *Discorsi* forecast the dangers which awaited him, like all those who have sought "new methods and new orders . . . undiscovered seas and lands." He "was a scapegoat because he was a great man and because he was unfortunate."

In judging Machiavelli one must likewise take account of his anguished despair of virtue and his tragic sense of evil. Again on the basis of sentences taken out of context and of outward appearances he was judged a cold and cynical man, a sneerer at religion and virtue; but in fact there is hardly a page of his writings and certainly no action of his life that does not show him to be passionate, generous, ardent and basically religious. To understand him nothing is better than the self-portrait which he drew in two lines of verse:

Io rido, e il rider mio non passa dentro:

Io ardo, e l'arsion mia non par di fore

("I laugh, and my laughter is not within me; I burn, and the burning is not seen outside.")

The Thinker and Writer.—Machiavelli had an eminently speculative mind. Unlike Guicciardini, who was empirical and pragmatic, he was irresistibly drawn to reduce human actions to scientific forms and rules, to go beyond particular facts and to seize on universal motives. The founder of the philosophy of history, he well knew (as he wrote in the preface to the *Discorsi*) that he was opening "a road as yet untrodden by man." As he had been the first to appreciate in histories "that flavour which they possess in themselves" beyond any merely literary or recreational ends, so he was the first to understand the doctrine of historical cycles and, starting from the principle that human nature does not change with the passing of time, the first to build a political science based on the study of man. The fallacy of always refer-

ring and holding to the example of the Romans without taking account of changed conditions was criticized, even in Machiavelli's day, by Guicciardini; but the latter was by nature inclined to concern himself rather with particular errors and inaccuracies than with his friend's universal theories. The *Discorsi* must have come into existence in the form of notes in the margins of a copy of Livy, which Machiavelli, as is known from his father's book, had been reading from the age of 17. They retained that form, but in substance they are a theoretical treatise on republics, as the *Principe* is a treatise on principalities (*De principatibus* was the book's original title).

Machiavelli's affections and theories were always for the republic; but the corruption of the times, the weakness of the states of Italy and the threat of foreign conquest made him long for that "new prince" who might give reality to his great dream of the redemption of Italy. This "redeemer" of his, to whom he sought in vain to give a face and a name, would have had to overcome superhuman difficulties; nor could there be much choice of means in attaining such ends. Machiavelli, in a book which is not a moral treatise, attempted to indicate to the prince those means which were compatible with the conditions of the time and with human nature. Even religion—for which he had a deep feeling though he was not outwardly pious—was subordinated by him, in matters of state, to the state's iron necessity and made into an *instrumentum regii*, or tool of power. Machiavelli indeed is regarded as the inventor of the "reason of state" (*ragione di stato*), though that expression appears for the first time 20 years after his death. The *Principe*, while its underlying ideas are the same as those of the *Discorsi*, won a greater reputation thanks to its concision, its vigorous imagery, the splendour of its close and energetic style and the bluntness of some of its aphorisms, which were taken too literally by contemporaries and by posterity. He remarked of certain cynical precepts that he would not have proffered them if mankind had not been wicked; and this bleak pessimism is certainly not refuted by the annals of his own time. Yet his longing was for a society of good and pure men; he sought it in ancient times and, for the present, admired less civilized nations as being less corrupt.

The *Arte della guerra*, properly considered, is merely complementary to Machiavelli's two political treatises, but it is more closely linked with the *Principe* and its great dream of Italian unity than with the *Discorsi*. Like the *Discorsi*, it has the defect of taking the ancient Romans at all costs and in everything as its model; and this fault appears greater in the *Arte* because too little attention is paid in it to technical advances, such as the use of artillery—which in those very years was beginning to make its weight felt decisively in battle. Even so Machiavelli can be said to have laid the foundations of modern tactics.

What has already been said about Machiavelli's hidden but strong and deep morality could be repeated in connection with the *Mandragola*, where the wickedness and corruption of men, particularly of the clergy, are the subject of laughter, but of a bitter and painful laughter which is never an end in itself. It reminds the reader of what was written about the author by one who had a better opportunity of knowing him than anyone else, his friend and critic Francesco Guicciardini: "He laughs at the failings of men because he cannot cure them." In the *Mandragola*, where the characters are no longer the stylized ones of classical comedy, but true-to-life Florentines, the character most lovingly drawn, in contrast with a stupid and pretentious doctor, is a ribald monk. There is no lack of comic force; but behind the scenes there is an occasional glimpse of tragedy. In this, rather than in its complete freedom from imitation of Plautus, lie the originality and the force of this extraordinary comedy, comic and shocking at the same time and highly poetic. The loose and static construction and the carelessness with which characters less interesting to the author are drawn make the miracle seem all the greater.

The *Storia fiorentina* also bears the impress of a powerful and original mind. In this work, written by fits and starts and unwillingly and wearily dragged on into his later years, Machiavelli enters on a new road, leaving behind him the traditions and methods of humanist historiography. He writes history more as a

politician than as a historian set on discovering the truth. He cares nothing for the criticism of sources and sometimes seems to have no scruples about accommodating facts to his thesis. It is not narrative exactitude which is to be sought in him, but the power of synthesis, the brilliant co-ordination and organization of facts. Machiavelli does not lack certain of the historian's qualities, but he lacks his interests: when he is writing he sometimes accepts without hesitation the most ingenuous sources and follows them page by page until he lights on a fact which fires his sympathies and his imagination or which awakens the theorist, the thinker capable of tracing the hidden connections and historical consequences of political phenomena. The same thing happens with his style, sometimes dormant in the *Storia fiorentina*, but always recovering its power when his interest revives, equaling the brilliance of the finest pages of the *Principe* and the *Discorsi*.

Machiavelli was a great writer because he was a great thinker. He was also a poet, but his poetry is to be found not so much in his verse as in his prose, which has no equal in Italian literature. It is also noteworthy that his excellence showed itself in nearly all the genres that he attempted: in historical writings, in political treatises, in the short story and, particularly, in comedy. It is to be regretted that he did not attempt tragedy, having all the qualities needed to excel in the theatre and a highly dramatic temperament.

Texts.—The edition of Machiavelli's works by P. Fanfani and L. Passerini remains incomplete after six volumes (1873-77) but is still the best for his reports of his legations. There is a collected edition of the historical and literary works by G. Mazzoni and M. Casella (1929); *Lettere familiari*, edited by F. Gaeta (1961). The *Discorsi* are translated into English by L. J. Walker, two volumes (1950); English translations of the *Principe* include those of E. Dacres (1640; reprinted 1929), L. Ricci (1903; reprinted 1955), W. K. Marriott (1908), A. H. Gilbert, with a version of Machiavelli's personal letters (1941), and P. Rodd (1954); and there are versions of the *Storia fiorentina* by N. H. Thomson, two volumes (1906), and by W. K. Marriott (1909). For a portrait of Machiavelli see ITALIAN LITERATURE.

MACHINE. A machine may be defined as a combination of resistant parts so connected as to have constrained motion and to be capable of transmitting or transforming energy. Although modern machines with their complex controls appear to be extremely complicated, every one is merely a combination of one or more of three basic elements: the wheel (*q.v.*) and axle, the lever (*q.v.*) and the inclined plane. Machines composed of combinations of these three basic machines may be classified according to two general functions: (1) generation and transformation of power; (2) transmission of power and performance of work, accomplished by means of such types of machinery as the pump, compressor, fan, crane, elevator and pulley (*qq.v.*) and the different types of vehicles. See also MACHINE TOOLS; MATERIAL HANDLING; and POWER TRANSMISSION. For specific machines not listed above, consult the Index.

MACHINE GUN, a military firearm of small calibre capable of rapid, sustained fire. The modern machine gun is an automatic, belt-fed weapon that, barring a malfunction, will continue to fire as long as the trigger is held back, or until the supply of ammunition is exhausted.

The first machine guns, such as the famous Gatling gun de-

scribed below, were manually operated by turning a hand crank, though they could be powered by a motor. The U.S. patent office described such weapons as being "capable of sustained fire from energy derived from an outside source." Later, truly automatic machine guns, such as the Maxim gun of the 1880s, required no outside source of power; they used the energy released by the burning propellant to feed, load, lock and fire each round, and to extract and eject the empty cartridge case.

The term automatic gun came into use after World War I to describe automatic aircraft weapons larger than the calibre .30 or calibre .50 machine guns. Such weapons were merely large machine guns (from 20 mm. to 57 mm.) and, as a rule, operated from energy released by the burning propellant. Beginning about 1945, some automatic guns reverted to the original external drive principle of the Gatling gun and employed either an electric motor or a gas turbine as a source of power. (For submachine guns, see SMALL ARMS, MILITARY; 20th-Century Small Arms.)

EVOLUTION OF THE MACHINE GUN

Soon after the advent of the first primitive firearms inventors began to contrive means for firing more than one shot before reloading. The first of these devices, known as ribaulds or ribaudequins, were simply bundles or rows of barrels, fired either all at once or in sequence. Many rather ingenious methods were used to control the firing, such as sliding locks that fired several superimposed charges in succession but required that the trigger be pulled for each shot. The idea of a multibore cylinder started in the matchlock period and has been used throughout the age of firearms, culminating in the most modern aircraft automatic guns. Before the invention of metallic cartridges, machine guns did not provide reliable, controlled ignition. They either suffered from stoppages or, even worse, permitted several charges to go off at once, with disastrous results.

The first soundly conceived manually operated machine gun was that patented in London, May 15, 1718, by James Puckle. The patent drawing of the Puckle gun has been widely published, but it is not generally known that the gun was actually produced, tested and found operable. Fig. 1 shows one of the production models in the Tower of London armouries. Puckle called his invention "a portable machine that discharges so often and so many bullets . . . as renders it next to impossible to carry any ship by boarding." The flintlock ignition was a limiting factor in its de-

REPRODUCED BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE, BRITISH CROWN ©
FIG. 1.—PUCKLE MACHINE GUN, 1718, WITH REVOLVING BLOCK FOR FIRING SQUARE BULLETS SHOWN IN THE FOREGROUND

sign, but other features were strikingly similar to those used in the Gatling and other systems of a century and a half later.

The Percussion Cap.—The many problems arising from inability to ignite all charges at the same time, or with a high degree of reliability, regardless of how close the barrels were grouped, held further development almost at a standstill until 1807, when

Alexander John Forsyth (1769-1843), a Scottish Presbyterian minister, patented an "application of the detonating principle to exploding gunpowder firearms." Forsyth utilized mercury fulminate, rolled into "pills" or small pellets which were placed in a nipple at the breech end of the barrel and detonated by the impact of a falling hammer.

Joshua E. Shaw (1776-1860), a U.S. sea captain, perfected a method whereby Forsyth's principle could be given a practical application—use of the percussion cap. Shaw developed a cup, made first of pewter and later of copper (about 1816), in which the mercury fulminate was placed so that the detonating mixture would be protected from the weather, would grip the sides of the nipple and could be used as a unit to transmit fire to the propellant charge. This invention opened the field for numerous weapons that were officially defined by the U.S. patent office as machine guns.

One of the earliest of the devices so classified was invented by Charles Emerson Barnes on July 8, 1856. Although there is no record of even a working model being made from the patent issued to the inventor, the illustration showing his toggle-locking action is still considered basically sound. Among other practical mechanisms of this period were the Ripley machine gun, the Ager "coffee mill" gun (commonly called the Union gun), the Claxton machine gun, the Williams machine gun and the Gorgas machine gun. The battle of Fair Oaks (Seven Pines), Va. (May 31, 1862), where the Confederates fired volleys from a battery of Williams guns, marked the first record of the use of the machine gun in warfare. There were, during the American Civil War, 11 hand-operated mechanisms that could be classified as machine guns available for service use. However, it remained for one man to resolve all the serious problems facing designers of manually powered machine guns at the time. That man was Richard Jordan Gatling (q.v.).

The Gatling Gun.—Gatling's original gun (about 1862) was a single-barrel device with a rotary chamber that combined certain features of the Ager and the Ripley guns. He employed the best ammunition available at the time. It consisted of a paper cartridge placed in a heavy-walled steel cylinder countersunk at the base and equipped with a nipple on which was placed the percussion cap. The first model of a Gatling gun using this type of cartridge was finished in time to see limited use by the Union army in the American Civil War.

Parallel with Gatling's efforts to improve gun mechanisms appeared the deciding factor which would govern the future of all machine gun design. It was first introduced to the sporting world in the form of the lightweight brass cartridge containing in a single unit a means of ignition, the propellant and the bullet. (See SMALL ARMS, MILITARY.) Gatling recognized the significance of this great improvement and redesigned his weapon. It consisted of a number of barrels mounted parallel one to another and equidistantly spaced to rotate about a central shaft. The gun was actuated by a hand crank which could be turned slowly or rapidly at the will of the operator, thus providing control of the rate of fire. The positioning of the incoming cartridge in the chamber of each individual barrel was accomplished by gravity or by the camming action of the cartridge container located directly above the gun. This was done while the chamber being loaded was making a half-revolution about the central shaft. Firing then took place, followed by extraction and ejection during the second half-revolution. The combination of all factors, from the basically sound mechanism to the self-contained metallic cartridge, was vitally necessary in the evolution and perfection of the Gatling machine gun.

The introduction of the self-contained metallic cartridge made possible not only rapid fire but also bursts of long duration with great reliability since the round could be mechanically controlled throughout the entire gun mechanism and the base of the cartridge could be designed to facilitate chambering, firing, extracting and ejecting.

Other Types.—The Gatling gun was without peer in the manually operated era and, when powered externally, could fire 3,000 rounds per minute. But its multibarreled arrangement placed a

serious limitation on its tactical use. This gave other inventors the opportunity to display their genius in devising variations of hand-powered machine guns to meet specific purposes. Among the foremost of these hand-cranked weapons was the Hotchkiss (1878) developed primarily for shipboard use, being chambered almost exclusively for the large artillery type of cartridge. More mobile than the Gatling, the Gardner was another successful mechanism employing conventional military rifle calibre cartridges only. It was adopted by the navies of many world powers because the one- and two-barrel versions could be easily carried ashore by one man. The prevailing military belief that volley fire was more effective than rapid continuous shots led to the development of another type of volley-firing, hand-powered machine gun, universally known as the Nordenfelt (patented in 1879). Although never officially adopted, many other ingenious hand-manipulated mechanisms were developed between 1865 and 1880 in the United States. These guns were actually constructed and passed exhaustive government tests. Representative types were the Lowell, which mechanically indexed and fed the incoming round at high speed; the Wilder, which combined the revolver system with reciprocating action; and the Bailey, which was the first to employ belt feeding.

During the American Civil War, French observers attached to the Union and Confederate armies recognized the devastating effectiveness of grapeshot fired from light artillery against concentrated attacking personnel. From these observations there was developed in Europe a peculiar multifiring weapon resembling a piece of standard artillery. It was considered an improved method of delivering grapeshot and was called a mitrailleuse, meaning grape shooter or more literally, grapeshot shooter. This marked the beginning of French interest in machine guns and each subsequent hand-powered or automatic firing device manufactured by the French carried the marking mitrailleuse, although the meaning of the word had no connection with the weapon beyond the first effort.

For the second time in machine gun history another completely new concept entered the field and quickly made all previous efforts obsolete. This revolutionary development came through the invention (about 1885) of a new form of propellant, a progressive burning powder. By gelatinizing nitrocellulose, the burning speed of the explosive mixture could be controlled to a high degree. Another important feature of this new powder was that during combustion there was almost no smoke. Quickly acclaimed by both military and civilian observers for its smokeless qualities, it was named smokeless powder. To the machine gun inventor, however, its real significance lay not in its lack of smoke but in its progressive burning qualities. It not only yielded a higher chamber and bore pressure to give increased velocity to the projectile, but also made it possible for a metered amount of gas pressure to be used for operating a weapon. By drilling a small hole or port in the barrel a fraction of the pressure could be brought to bear on a piston or lever that provided complete control during firing.

Still another method for powering the weapon was provided by the recoil force which was also governed solely by the progressive burning qualities of the new propellant. When the weight of the charge was constant it gave the same amount of thrust with each shot. This assured consistency of the distance and speed of the recoil stroke.

Hiram Stevens Maxim (1840-1916), a U.S. engineer and inventor residing in England, conceived the idea of the first fully automatic machine gun. Again, the conception and development of the automatic machine gun was retarded initially because the inventor was forced to employ as ammunition only what was available at the time, in this case the conventional black powder cartridge. In spite of this handicap, by June 1884, Maxim had progressed to the point where he had a workable product. The principle of short recoil was used by Maxim for the complete cycling of his single-barrel weapon. Although Maxim's early experiments were conducted with black powder cartridges, and he had reached a limited degree of success, it was the introduction of the new propellant, smokeless powder, that not only assured the

success of the Maxim gun but also brought about the golden era (from 1884 to World War I) of automatic machine gun inventions. His guns, as manufactured by Vickers and known by that name as well as Maxim or Vickers-Maxim, were used by every major power. The Vickers machine gun was adopted by the U.S. army as its model 1915.

Following closely behind Maxim came the prolific U.S. inventor, John M. Browning (*q.v.*), of Ogden, Utah. His work on automatic gun mechanisms is well known; no design of his ever failed. After his entry into the field the United States used his automatic weapons almost exclusively. Official adoptions by the U.S. include the calibre .30 Browning automatic rifle (B.A.R.), the calibre

be combined with the machine gun as a weapon of war of vast potentiality.

Throughout automatic weapon history, new situations that stimulated design always appeared. By World War I, when the ground-type machine gun had reached a stage of near perfection, aviation provided an incentive that opened up fresh concepts in automatic weapons. Certain features, hitherto unforeseen, became immediately critical. Among these were weight, compactness, high rate of fire, amount of ammunition used in comparison with allowable weight to be carried by the airplane, synchronization to fire through the propellers, mounting of weapons and ejection of empty cartridges and links. At first, with the slow flying speed, these problems were easily overcome; in fact, planes originally carried regular ground-type machine guns with slight modifications for mounting purposes.

Machine gun designers managed to stay ahead of aircraft requirements throughout the 1920s, 1930s and the early part of World War II. However, the advent of jet-powered aircraft in the latter days of World War II introduced a new factor in machine gun design. The problem was to design an extremely light, large-calibre gun shooting an explosive projectile at a very high rate of fire to cope with the supersonic speeds, tremendous stresses and compact design of jet aircraft. However, advances in impact forming had by then developed the art of stamping to such close working tolerances that the forging and machining of receivers, feed mechanisms and internal parts became unnecessary. Metallurgists, successful in the development of new alloys of high tensile strength, found they could replace steel when weight became the important factor. As these things came into being, the weight of the automatic gun was considerably reduced, thus allowing more installations of guns per aircraft and more firepower per pound of weight carried.

To this end scientists and machine gun designers worked constantly to produce reliable, light, compact, rapid-firing automatic guns to keep pace with the ever-advancing aircraft industry. There has been a universal exploitation of systems to take advantage of certain features that are highly adaptable for a specific purpose and to design an automatic firing mechanism having the desired

BY COURTESY OF THE U.S. ARMY

.30 light Browning machine gun, the calibre .30 heavy Browning machine gun, the calibre .45 auto-loading pistol, the calibre .50 aircraft and heavy-barrel ground-type Browning machine gun and the 37-mm. aircraft automatic gun.

From 1890 to World War I, the large standing armies prevalent in Europe furnished an impetus and ready market for tremendous activity in machine gun design, and there was an influx of U.S. automatic weapon designers to Europe. Among them were Hugo Borchardt, Benjamin Hotchkiss, Laurence V. Benét, Col. Isaac N. Lewis and later Browning. Consequently, both the Allies and the Central Powers during World War I armed their military forces with machine guns designed by persons of U.S. origin, such as the Maxim, Vickers, Lewis, Hotchkiss, Benét-Mercié and Browning.

The Skoda gun was used by Austria and tested by the United States. The Madsen light machine gun, made in Denmark, was used by Russia, Denmark, Norway, Argentina and several other countries. The Bergmann and Dreyse guns were used by Germany. The Schwarzlose was used by several countries. Before and during World War I, the Chauchat, Benét-Mercié, Berthier and Lewis light machine guns were extensively tested and used. During that war, the Lewis gun, in an adaptation for aircraft, became one of the favourite weapons of fighter pilots. Some of them were still in service at the beginning of World War II. A famous gun, the ZB, was developed in Brno, Czech. The British government acquired a licence to manufacture it before World War II and used it extensively. The weapon was manufactured at the Enfield plant and called the Bren gun, the name being derived from Brno and Enfield.

Designers of other nations active during this time included Germans such as Paul Mauser, Fritz and George Walther, Theodor Bergmann, Louis Schmeisser and Reinhold Becker; the Austrian, Rudolf Frommer; the Italians, Bethel Revelli and Alfredo Scotti; the Frenchman, André Berthier; the Swiss, Marc Birkigt; and the Mexicans, Manuel Mondragon and Rafael Mendoza. Their designs, then still in experimental stages, were not used extensively during World War I, but they laid the foundations for many subsequent developments.

World War I, often called the machine gun war, brought to the foreground the importance of the machine gun as a deadly military weapon. Lloyd George, in a speech before the British house of commons on Dec. 15, 1915, estimated that over 80% of the British casualties to that date had been inflicted by machine gun fire and it is reasonable to assume that the other participants suffered in the same ratio. This great conflict also introduced a hitherto unproved weapon, the airplane, which was destined to

BY COURTESY OF U.S. DEPARTMENT OF ARMY

FIG. 3.—U.S. MACHINE GUN, M60, ADOPTED IN 1957

qualities. This resulted in a great advance in aircraft automatic weapon design. In 1957 the U.S. army adopted the M60, a light-weight, general purpose machine gun to replace three older calibre .30 machine guns. The gun could be fired from the shoulder, from the hip, from a bipod or from an aluminum tripod mount. It was chambered for the standard 7.62-mm. NATO (North Atlantic Treaty organization) cartridge.

AUTOMATIC GUNS

When aircraft were first used in combat during World War I they were armed with the types of small arms then used in ground warfare, but machine guns specially designed or adapted for mount-

ing in aircraft were soon developed. Some were mounted in open cockpits while others were installed to fire through the propeller—synchronized so as to miss the blades. Before the end of the war, it was evident that a heavier weapon was needed for firing at ground targets such as trucks, locomotives or light tanks. Some of the first attempts at a solution simply placed in the airplane a conventional light fieldpiece with so-called quick-fire breech mechanism. As the recoil energy to be absorbed by the aircraft structure was excessive, it became apparent that specially designed weapons were required. The Puteaux factory in France modified some 37-mm. aircraft cannon designed by Birkigt (of Hispano-Suiza) to fire through the hub of a propeller. But these did not go into service until after World War I. The Germans had placed a 20-mm. Becker gun in a ring mount and found it an effective aircraft weapon. This was the forerunner of the 20-mm. Oerlikon gun of World War II service.

In 1938 the Royal Navy adopted the 20-mm. Oerlikon gun as its standard light antiaircraft weapon on all ships. A short time later the U.S. navy took similar action. During World War II, both Japan and Germany also used the Oerlikon extensively. It was the principal Nazi aircraft gun before and during the battle of Britain.

One of the first automatic aircraft cannon used in World War I was the Revelli (Fiat) which the Italians installed in their large Caproni and Savoia-Pomilio bombers. The calibre of this gun was 25.4 mm. It could fire eight rounds in two seconds from a ring mount. The British Vickers 37-mm. automatic aircraft cannon was installed in British naval aircraft as early as 1915. Its excessive recoil made it unpopular, but during the 1930s, Vickers improved the design and produced some 37-mm. guns which were satisfactory. The size was later increased to 40 mm., and near the end of World War II a few of 57 mm. were produced.

In the United States, a Browning 37-mm. aircraft cannon was used to some extent during World War II. The U.S. government furnished thousands of these weapons to Russia with Bell Airacobra fighter planes. Most U.S. aircraft carried 20-mm. guns of either Hispano-Suiza or Oerlikon type.

The principal gun used by the army air forces was the 20-mm. M1 and AN M2, which operated on a combination gas and blowback principle. It used either a belt-feed mechanism or a 60-round drum magazine. It was mounted as a fixed gun in the wing or fuselage of an airplane, or in a turret. It could also be mounted to fire through the propeller hub. Its rate of fire was 600 to 700 rounds per minute.

The French developed but did not use a 25-mm. Hotchkiss gun. They did not use it because the plant was captured early in the war. Japan, however, made the gun on a licence agreement and used it extensively. The Italian Scotti gun superficially resembled the Oerlikon, but was not used to any extent. The Danish Madsen guns in 20 mm. and 23 mm. were never very popular. The Nazi forces during World War II used several different aircraft guns, among them the Mauser 20-mm., and the Rheinmetall-Borsig in 20-mm. and 30-mm. sizes. The Swedish Bofors plant also produced aircraft guns in 20-mm. and 57-mm. sizes. Breda made some 20-mm. guns for the Italian government.

Most of the early automatic aircraft guns were mounted on flexible rings. However, some were arranged to fire through the propeller hub, and a few, notably types used in heavy U.S. bombers during World War II, were placed in remotely controlled turrets. But the weapon most commonly used in such turrets was the calibre .50 Browning machine gun. As first adopted by the U.S. services, this gun was known as the model 1921. It was made with either water-cooled or air-cooled barrels. The former were for anti-aircraft use, the latter, either with flexible or fixed mounts, for aircraft installations. The principal type used during World War II was the M2, which is distinguished from earlier models by the fact that it could be fed either from the right or left side. Older guns fed from the left only. The variants of the M2 included aircraft models (fixed and flexible), heavy-barrel models for ground use and water-cooled models for anti-aircraft fire. The aircraft guns could be fired mechanically or electrically either by an accessory or by a manual trigger. Their rate of fire was from

750 to 850 rounds per minute. The AA version had a rate of from 550 to 700 shots per minute, while the heavy-barrel ground gun fired at from 400 to 500 shots per minute. Late in the war an improved gun, the M3, was introduced. Its main distinction was an increased rate of fire—1,200 shots per minute.

In the Korean War the predominant weapon on planes of the United Nations was the calibre .50 aircraft gun. The Soviet MIG-15 planes were armed with a variety of larger calibre, slower firing weapons ranging in size from the calibre .50 to the 37 mm., including a 23-mm. gun with a cyclic rate of 700-800 rounds per minute. To meet the challenge of supersonic jet planes, aircraft guns firing at the rate of several thousand rounds per minute were under development. One adopted by the U.S. air force was a 20-mm. machine gun operating on the revolver principle, with a five-chamber cylinder. Another model unveiled in 1957 was the 20-mm. Vulcan based on the Gatling gun principle. Its six rotating barrels could fire at the rate of about 7,000 rounds per minute. In spite of these developments, aircraft rockets and guided missiles steadily gained ground in competition with conventional machine guns. (See ROCKETS AND GUIDED MISSILES.)

SYSTEMS OF OPERATION

Generally speaking, there are five known practical applications for accomplishing sustained fire as outlined in the definition of an automatic gun: (1) residual pressure remaining in the bore a few milliseconds after the projectile has cleared (blowback); (2) gas pressure in the bore bled off externally through an orifice (gas operation); (3) long recoil; (4) short recoil; and (5) blast energy generated by the expanding gases after being released from the confines of the barrel at the muzzle end (muzzle blast actuation). The last application has had only limited development in automatic weapon design and is not further discussed in this article.

Principles of Blowback.—In some guns, all the energy required for the performance of the automatic cycle is obtained through blowback action while in others only a portion of the required energy is from this source, the remainder being derived from some other system of operation. In any event, the blowback effect is present, at least in part, whenever the bolt of a gun is not locked while there is powder gas pressure in the chamber. When blowback action occurs, the energy derived from the pressure of the powder gases appears in the form of kinetic energy transferred to the bolt mechanism by the empty cartridge case as it is blown from the chamber of the barrel; *i.e.*, it appears in the form of a velocity imparted to the bolt mass. The basic problem involved in blowback operation is in the complete control of this velocity so that the gun will operate as desired. There are several well-defined methods by which the control of the rearward motion of the bolt may be accomplished in guns employing blowback and these various methods are referred to as blowback "systems."

Plain Blowback.—This system is used extensively in the design of lightweight shoulder arms chambered for short-range pistol cartridges. This type of weapon is officially designated as a submachine gun—the Thompson calibre .45 submachine gun, for example. The method is also universally employed in construction of small-bore, auto-loading hand arms; *e.g.*, the calibre .22 Colt Woodsman pistol. In the plain blowback system (see fig. 4), the

FIG. 4.—SCHEMATIC DRAWING OF PLAIN BLOWBACK SYSTEM

bolt returns to the firing position with relatively low velocity but with considerable kinetic energy and this energy is absorbed by impact before the next cycle starts. Since the bolt is stationary when the new round is fired, all of the explosive force of the round is effective in accelerating the bolt to the rear. As has been explained, this condition requires the use of an extremely heavy bolt in order to keep the bolt velocity within safe limits.

Delayed Blowback.—This may be defined as a method of opera-

tion in which the bolt remains locked until the peak powder gas pressures have passed and a safe operating limit is reached after the projectile clears the muzzle. The bolt is then unlocked by some means so that it can be blown back by the residual pressure with sufficient energy to perform the remainder of the cycle of operation. In this system, the time at which the bolt is unlocked can be controlled in the design so that any desired portion of the residual pressure can be utilized. Of course, the bolt must be unlocked while there is still sufficient impulse available from the residual pressure to produce the required operating energy.

Any gun in which the bolt is unlocked while residual pressure still exists is subject to some blowback and partakes of some of the characteristics of the delayed blowback system. Such guns include certain gas-operated and short-recoil-operated weapons in which the bolt is unlocked almost immediately after the projectile has left the muzzle. However, in guns of this type, the operating energy does not come solely from blowback but is derived also from the action of the gas piston or from a mechanical accelerator actuated by the motion of the recoiling parts. This system is highly adaptable to large calibre automatic guns, such as the Birkigt 404, Hispano-Suiza and Scotti aircraft weapons.

Retarded Blowback.—In this system a special retarding mechanism is operated by the movement of the bolt. The mechanism itself is composed of relatively light parts and the inertia forces which result when these parts are set in motion by the bolt are therefore relatively small. However, the mechanism is arranged so that the bolt must act through a tremendous mechanical disadvantage to overcome the inertia forces and is accordingly subjected to a very high resistance to motion. In other words, although the bolt and the associated mechanism may be quite light, the effective resistance to bolt acceleration can be made just as great as that which would be obtained by the use of an extremely heavy bolt. The mechanism of a retarded blowback gun is similar to that of a plain blowback gun except for the presence of the retarding mechanism. This can take many forms but the basic principle underlying all of these is that the bolt must overcome the inertia forces in the mechanism by acting through a high mechanical disadvantage. Being unadaptable to large bore weapons, this system is used exclusively in design of machine guns employing rifle or pistol cartridges; e.g., the Schwarzlose and Skoda machine guns.

Advanced Primer Ignition.—A substantial saving in bolt weight and other advantages can be realized by making use of the kinetic energy of the returning bolt. Instead of permitting this energy to be dissipated by impact before the next round is fired, it is possible to time the ignition so the new round is fired just before the bolt reaches its fully forward position. In this method, known as advanced primer ignition, the impulse of the propellant explosion must first slow and stop the returning bolt before it can propel the bolt to the rear. With this action, only a portion of the explosive impulse is effective in blowing the bolt back and the interval of time during which the pressure of the powder gases acts to produce a rearward acceleration of the bolt is also reduced. Both of these effects permit the use of a much lighter bolt and produce a condition in which higher bolt velocities are allowable. Thus, not only can the gun be lighter, but it is also possible to achieve a higher rate of fire. This operation is used exclusively in the design of large bore automatic guns; outstanding examples are the Oerlikon and the German MK-108.

Principles of Gas Operation.—In all machine guns, the fundamental source of operating energy is the high-pressure gas created by the explosion of the propellant charge. This is true, in a general sense, of guns operated by any system of true automatic operation, as defined in this article. In spite of the fact that the ultimate source of operating energy in all machine guns is the pressure of the powder gases, the term gas operation is reserved for a particular type of operating system in which the pressure of the powder gases is employed in a specific way.

In a typical gun which uses the system of gas operation, an opening or port is provided in the side of the barrel. When the projectile has passed this opening, some of the high-pressure gases behind the projectile are tapped off through the hole and pass through an orifice to operate a piston or some similar device for converting the

pressure of the powder gases to a thrust. This thrust is then utilized through a suitable mechanism to provide the energy necessary for performing the automatic functions required for sustained fire. These functions include unlocking the bolt, retracting the bolt and operating the other portions of the gun mechanism necessary to perform the complete cycle.

The gas operating mechanism can take many forms. Fig. 5 illustrates a commonly used device, consisting of a simple gas cylinder

FIG. 5.—SCHEMATIC DRAWING OF GAS-OPERATED SYSTEM

der and a piston which is driven rearward to transfer its energy to the bolt by direct impact. In some cases, the piston may be driven forward instead of rearward, but this does not involve any significant change in the principle of operation. Even the nature of the member which is acted upon by the gas pressure is subject to great variation. Instead of being a conventional piston, this member can be in the form of a sleeve, slide or other device arranged to receive an impulse from the gas pressure.

The methods used for transferring energy from the piston to the gun operating mechanism are also extremely diverse in form and function. Instead of transferring energy directly to the bolt, the piston itself sometimes moves through a very short stroke and transfers its energy by impinging on an intermediate sliding member or lever. A great number of devices have been designed to minimize the shock involved in the energy transfer through the use of levers, links or cams. In certain instances, the shock of transfer is reduced by causing the piston to load intermediate springs which subsequently transfer their stored energy to the mechanism. Existing examples of gas-operated guns (e.g., the Hotchkiss) incorporate many ingenious arrangements for tapping the energy in the powder gases and for handling related problems such as sealing, timing and adjustment.

Principles of Recoil.—These principles can be understood best by considering the forces which result from firing a cartridge in an elementary gun. Such a gun consists of a barrel having a chamber at its rear end for receiving the cartridge and a breech closure in the form of a bolt. The bolt is rigidly locked to the barrel after the cartridge is inserted and provides a firm support for the base of the cartridge case so that the case will not be blown out of the chamber by the explosion of the propellant charge. When the cartridge is fired, the explosion of the propellant results in the rapid generation of extremely high gas pressure in the chamber and the expansion of this high-pressure gas drives the projectile forward through the bore. As the powder gases expand behind the projectile, the centre of mass of the gases also moves forward. While the projectile is in the bore, the same pressure which causes the projectile and powder gases to move forward also acts simultaneously at the breech end of the gun to produce an equal and opposite reaction which tends to drive the entire gun to the rear. The force resulting from this reaction is called the recoil force, and the magnitude of this force at any instant depends on the chamber pressure.

The distinguishing characteristic of any recoil system is that energy used for operation is obtained from the recoil movement of

FIG. 6.—SCHEMATIC DRAWING OF LONG RECOIL SYSTEM

the barrel and bolt while these parts are locked together. Any gun in which the bolt is locked to the barrel while there is pressure in the chamber will be subject to some recoil action, but unless the recoil is put to use in actuating the gun mechanism, the weapon is not considered to be recoil operated.

Long Recoil.—This type is defined as an operation in which energy for operating the gun mechanism is obtained from a recoil movement which is greater than the over-all length of the complete cartridge. (See fig. 6.) During this entire movement, the bolt remains locked to the barrel. At the end of the rearward movement, the bolt is unlocked from the barrel and is latched in its rear-most position, the barrel moving forward in counterrecoil to pull the chamber off the empty cartridge case and eject the case. When the barrel has moved forward far enough to provide a sufficient opening for feeding, and just before its counterrecoil movement is completed, the bolt is unlatched. The bolt then moves forward for loading and the cycle is completed as the bolt relocks to the barrel (e.g., the Browning 37-mm. aircraft cannon).

Short Recoil.—In this system, the barrel and bolt remain locked and recoil together for a short distance until the powder gas pressure has dropped to a safe limit. The recoil movement then unlocks the bolt and, after unlocking, the barrel is stopped while the bolt continues to move to the rear until the opening between the barrel and bolt is sufficient to permit feeding. It would be possible for the bolt to complete this movement merely by the momentum it possesses at the instant of unlocking, but in all short recoil weapons, in order to speed up operation, the bolt is given additional momentum by an accelerating device which transfers energy to the bolt from the barrel during the short time that the barrel is still moving to the rear after unlocking. Also, unlocking usually occurs before the residual pressure reaches zero and therefore the bolt receives an additional impulse from blowback action. The basic elements of a short-recoil mechanism are shown in fig. 7.

FIG. 7.—SCHEMATIC DRAWING OF SHORT RECOIL SYSTEM

The Browning calibre .30 and calibre .50 machine guns represent this type of action.

MACHINE TOOLS. Of the many power-driven tools that have been developed, machine tools are probably the most important, because it is by means of them that other tools such as those for earth working, materials handling, etc., are made. They are important also because they have made it possible to produce identical parts shaped to sufficiently precise dimensions as to provide complete interchangeability. Interchangeability of parts has made possible the assembly of products on a mass-production scale and the quick and inexpensive replacement of worn and broken parts.

Machine tools are often defined as power-driven machines, ordinarily not portable by hand, which cut, shear, or press metal into desired forms. Though they may be classified in various ways, perhaps the most meaningful arrangement is according to their respective modes of shaping materials, usually metals, which they are designed to work. (See table below.) Figs. 1-6 show the basic method of operation of various classes of machine tools.

Although evidence indicated that man first used hand tools during the Early Stone Age (35000 to 15000 B.C.), it is interesting to

Classification of Machine Tools

Classification	Process	Machine tool
Cutting	Turning	Lathe
	Drilling and boring	Drill press, boring machine, lathe
	Milling	Milling machine
	Planing	Planer
	Shaping	Shaper
	Slotting	Slotter, keyway miller
	Sawing	Power hack saw, band saw, circular saw
	Broaching	Broaching machine
	Filing	Filing machine, band file
	Generating	Hobbing machine, gear generator
Shearing	Shearing	Power shear, rotary shear
Abrading	Punching	Punch press, nibbler
	Grinding	Grinder
	Honing	Honing machine
	Lapping	Lapping machine
	Polishing and buffing	Polishing machine, buffing machine, speed lathe
	Abrasive blasting	Sandblast, shot blast, liquid blast
	Tumbling	Tumbler, tumbling barrel, vibratory bowl
Forming (impact, bending, squeezing and pressing)	Forging and upsetting	Forging press, drop hammer, 2-movable die impactor, forging machine, die-rolling mill, header, upsetter, explosion forging
	Swaging	Swaging machine, rotary swager
	Hammering	Power hammer, hammering machine
	Bending and forming	Roll bender, press brake, roll forming mill
	Stamping and deep drawing (punching, bending, forming, shallow drawing, swaging, coining, shaving and trimming)	Stamping press, punch press, drawing press
	Extruding	Extruding press, impact press (Special device and energy source for each process)
	Flame cutting	
	Spark disintegration	
	Ultrasonic grinding	
	Electrochemical disintegration	
Other metal-removing processes	Chemical milling	
	Electron or radiation beam disintegration	

note that the machine tools listed below were themselves originated and developed in the very short span of about 400 years, beginning in the 16th century. Leonardo da Vinci's records show a lathe with a pole drive apparently in use in the 1500s. The basic tools in this list, however, did not assume their present general forms and characteristics until mechanical power became available during the Industrial Revolution beginning in the latter part of the 18th century. In 1794 Henry Maudslay developed his first all-metal lathe with a sliding tool rest. John Wilkinson improved the lathe for boring purposes in 1776 for James Watt. Maudslay's adaptation of the lead screw to his lathe in 1810 made possible the construction of lathes, planers, and milling machines in quantity and really laid the basis for the modern family of machine tools. By 1840 these tools were fairly well established as productive machines for industrial use. Their objective is two-fold: to provide much greater power than man himself can furnish to form and shape certain of his materials of construction; and to give him skill and precision in this work.

The basic machine tools are the lathe (q.v.), milling machines, drilling machines, broaching machines, sawing machines, shapers and planers, gear-cutting and metal-forming machines.

Milling Machines.—This class of machines employs a cutting process in which rotary cutters with multiple teeth are used. Flat or formed surfaces usually are produced. Diesinking (q.v.) is a milling process involving formed end mills for producing contour surfaces. The cut of each tooth is not continuous but intermittent

on the feeding side of the cutter. In general, the cutter, mounted on an arbor fitted into the end of the spindle (a face mill is attached to the end of the spindle), rotates to provide cutting speed, while the work, mounted on the table, is fed into or past the cutter. The commonest operation is plain milling, using a cylindrical or circular section cutter, of the

FIG. 1.—BASIC MACHINE-TOOL OPERATIONS: TURNING

profile or formed type, with teeth on its periphery; side or face milling employs a cutter with teeth projecting from its end, while end milling is a combination of plain and face milling. Milling cutters can be made in a variety of shapes for specific operations.

Milling machines differ widely in construction and use. A classification may be based on general appearance (column-and-knee or fixed-bed type) or design (plain or universal; bench or floor mounting; horizontal or vertical spindle; hand, mechanical [lead screw], or hydraulic feed) or on the type of work handled (job shop or manufacturing; thread milling and planetary milling; diesinking).

Historically, milling is supposed to have originated in the 16th century; the cutter resembled a circular saw or rotary file with a large number of cutting edges spaced about its periphery. The first successful milling machine was built by Eli Whitney prior to 1818. Simeon North also used a plain miller in 1820 to manufacture firearms. The first universal knee-type miller is believed to have been built in Windsor, Vt., in 1852. In 1855, a fixed-bed or manufacturing type of miller was built by G. S. Lincoln in Hartford, Conn. This used the screw-and-nut table feed instead of the earlier rack and pinion. In 1862, the first fully universal milling machine, equipped with a universal dividing head, was built by J. R. Brown and used for cutting helical flutes in twist drills.

In 1906 the feed mechanism was driven from the single pulley drive shaft (making it possible to express the feed in inches per minute) rather than from the spindle (which gives inches per revolution of the spindle); in other words, it was possible to achieve constant feed per tooth of the cutter for all spindle speeds. The feed in inches per minute is the product of the feed per tooth, the number of teeth in the cutter and the rotational speed of the cutter.

The column-and-knee milling machine is used for general work in small quantity production. A rigid vise rests on the table for holding the work. In the plain type machine three motions of the table are possible (longitudinal, transverse and vertical), while the universal type, having a swivel table, permits a rotational motion. The spindles fixed in the head of the column, either vertically or horizontally, have only a rotating motion. The spindle of the vertical machine may be fixed in the head of the column or provided with a quill to permit the spindle to be fed vertically by hand or power. Hand millers are usually small for light work, of the column-and-knee type. The table is fed longitudinally by hand.

The fixed-bed types, or manufacturing millers, offer rigid construction and simple operation for production of relatively small parts. The spindlehead is adjustable vertically on the column, and the table has only longitudinal feed. Large machines of this general type are called planer millers. Rotary millers, which are usually of the vertical spindle type, have tables provided with fixtures; they are used for mass production in which the cutting is continuous, that is, there is no idle machine time, as the operator loads the fixture in front of the cutter and removes the finished parts prior to loading the next piece. Thread-milling machines are designed to cut threads and

FIG. 2.—BASIC MACHINE-TOOL OPERATIONS: PLANING

worms using form-milling cutters rather than single-point tools.

The horizontal boring, drilling, and milling machine is provided with a horizontal spindle which is adjustable on the column and may be fed both longitudinally and vertically. The table on which the work is clamped may be fed longitudinally and transversely, or the machine may be provided with a rotary table. An almost unlimited variety of operations of boring, drilling, threading, and milling may be performed on such a machine. Recently developed omnidirectional mills use a traveling, tilting head with quill feed from any angle to complete operations on all sides of a workpiece. Tools are changed rapidly with mechanical assistance. The cutting edges are preset in position in the tool holders so as to cut right to size, with minimum delay for trial and adjustment. Also, greater accuracy is attained, since the workpiece requires no shifting or reclamping between cuts.

Drilling Machines.—A drilling machine, or drill press, is designed to hold a drill or other end-cutting tool in a spindle rotated and fed by power. The size of most drill presses is expressed by the diameter in inches of the largest circle whose centre can be reached by the drill.

Drilling machines are made in many different types and sizes, each designed to handle a class of work or specific job to the best advantage. The classification is based on design or construction,

FIG. 4.—BASIC MACHINE-TOOL OPERATIONS: GRINDING

purpose, and application of power. Upright drilling machines, of the single-spindle type for floor mounting, are general purpose machines. They are provided with a wide range of spindle speeds and feeds, and a table, vertically adjustable on the column, on which the work is supported. Tools such as drills, reamers, taps, and counterbores, in interchangeable quick-change holders, may be used successively to finish holes in a part. In production, upright drilling machines are often mounted in gangs of two to eight, on a common base, so that successive operations may be performed on a part as it is passed from one spindle to the next. A multiple-spindle vertical drilling machine may have a fixed number of spindles, radially adjustable in a head so that all holes in one face of a part produced in small lots may be drilled simultaneously. Other multiple-spindle drill presses for mass production have the spindles built on fixed centres into the head for a given job. If the job is changed the head must be replaced.

The radial drilling machine carries a spindle in a head mounted on a horizontal arm, the arm in turn being vertically adjustable on a column about which it swivels. The head may be moved radially on the arm, and the spindle moved vertically in the head, by hand or power feed. Radial drills are employed for general utility work, particularly on large castings and weldments. They are rigidly constructed and are provided with a wide range of speeds and power feeds; they may be used to drive drills from one-eighth to three or four inches in diameter, as well as large boring tools, taps, etc.

A deep-hole drilling machine, with one or two horizontal spindles, is used for such work as drilling gun barrels. The barrel is rotated at high speed while a single-lipped, sintered-carbide-tipped drill, provided with a high-pressure system for applying cutting oil at the drill point, is fed into the work. For short work, such as drilling oil holes in connecting rods from the crankpin to the wrist-pin hole, vertical multiple-spindle machines operating on the same principle are used.

Way drilling machines for mass production of parts are built for each job and may consist of several multiple-spindle heads carrying drills, reamers, boring tools, and even milling or threading tools operating simultaneously on one or several faces of the work. These are built in horizontal, vertical, and a combined form. The transfer machine, an outgrowth of the way drill, represents the

FIG. 3.—BASIC MACHINE-TOOL OPERATIONS: (A) DRILLING AND (B) BORING

FIG. 5.—BASIC MACHINE-TOOL OPERATIONS: PRESSING: (A) WORKPIECE IN POSITION; (B) DIES CLOSED

ultimate production tool. A complicated part such as a cylinder block is carried on a transfer bar from one machine to the next while it is machined on all surfaces successively and then discharged at the end. All clamping and transfer is automatic.

Boring machines, capable of drilling or boring, are made in a variety of types and sizes for specific jobs. Precision boring for mass production of relatively small parts, such as piston-pin holes, employs one or more horizontal spindles which carry single-point tools with diamond or sintered-carbide tips. These tools operate at very high speeds to finish the previously drilled holes in such parts as bushings and aluminum pistons to great accuracy and smooth finish. The jig borer is used to drill, bore, or finish holes within very close limits in such work as drilling jigs, multiple drilling-head parts, and dies which are accurately spaced. They drill, bore, or ream as required.

Broaching Machines.—These machines finish surfaces by drawing or pushing one or more cutters, called broaches, entirely past the surface. The broaches have a series of cutting teeth, increasing in height from the leading end. The first teeth are low to permit the broach to enter the hole (in internal broaching), or to pass over the surface (in external broaching), to catch any unforeseen high spots. The first few roughing and intermediate teeth remove most of the metal; the last few, taking lighter cuts, finish the hole or surface to size. Broaching machines may be horizontal or vertical. The broach may be pulled or pushed, or, in some cases, work is held in fixtures on a chain belt which moves past stationary broaches. Most machines are operated hydraulically.

Many broaching operations are completed in the time ordinarily taken to clamp the piece. Broaching is superior to reaming because the broach will hold its size for a much longer time, thus insuring greater accuracy. Other advantages are the good finish, great speed of production, interchangeability of work, and adaptability of the broach to produce irregularly shaped holes or forms, such as splines. The broach will machine many more pieces before regrinding than any other type of cutter, because of the great number of teeth. Each tooth removes but a few thousandths of an inch of metal because the total depth of cut is proportioned over the total number of teeth.

Sawing Machines.—Saws for parting metals consist of thin disks of metal with cutting teeth on the periphery, or a band of metal with teeth formed on one edge. To eliminate binding between the cut surfaces and the side of the saw, either the teeth are "set" (bent alternately to each side) or the blade below the edge of the cutting teeth is hollow-ground. The width of the groove cut by the saw blade is called the kerf.

Three types of metal-sawing machines in common use are the hack saw, band saw, and circular saw. The power hack saw has a short, straight blade that is mounted under tension in a frame and reciprocated over the work in a straight line. The teeth are forced against the work on the cutting stroke by gravity, spring pressure, hydraulic pressure, or positive screw feed, but lifted on the return stroke to avoid dragging the cutting teeth over the work. The reciprocation on small machines is by crank and connecting rod. On some of the larger machines this is done by crank or hydraulically. The smallest machine of the reciprocating blade type is known as the jig saw. The blade, clamped at its lower end, moves vertically through an opening in a horizontal table. The power hack saw has a vise under the saw for clamping the work. The small machines will take work up to 4 in. square in section and the largest up to 14 in. The small machine uses blades from 12 to

18 in. in length, while the largest machine uses blades up to 24 in. Blades have from 4 to 18 teeth per inch, the coarse teeth being used for large, solid work and the finer teeth for tubes, sheets, and small bars.

Band saws employ a long, endless strip of steel with teeth on one edge, carried over two large-diameter rotating wheels. This blade passes down through a table on which the work is mounted and fed by hand or screw into the saw. A guide to prevent the saw from deflecting is adjustable just above the work. The machines vary in size with bands from $\frac{1}{4}$ in. to 18 in. in width. Power is applied to the lower wheel and the sawing action is continuous.

Circular saws have disk-shaped blades that may be classified in three groups: cold sawing, abrasive disk, and high-speed friction disk. Cold sawing is a milling operation using thin, metal-slitting saws of any desired diameter and the correct number of teeth and tooth shape for any metal. Standard milling machines are used with light cuts per tooth and conventional cutting speeds of 50–150 ft. per minute (fpm) with high-speed steel cutters on hard to soft steel, or 400–1,000 fpm for brass and aluminum. For large cold saws, 12–72 in. in diameter, special machines are constructed. These machines may be used to cut a bundle of bars or one large bar at a time, held rigidly in a vise. Abrasive disks made of silicon carbide for cast iron and nonferrous metals, or aluminum oxide for steel, are produced in wheels from $\frac{1}{8}$ to $\frac{1}{2}$ in. thick and up to 14 in. in diameter. These wheels are particularly effective on hard, abrasive material and may be run safely at 12,000–16,000 fpm. They are interchangeable with steel-friction saws.

Steel-friction disks are carefully balanced and hollow-ground, usually with teeth hobbled or notched in the edge. These saws range up to 60 in. in diameter and $\frac{3}{8}$ in. in thickness and are run at peripheral speeds of 18,000–20,000 fpm. This speed and the pressure against the work melts the metal and carries it away. Hot or cold bars may be parted, and rails, channels, etc., from rolling mills can be cut to length in a matter of seconds.

Shapers and Planers.—The shaper was developed to machine flat surfaces on small work. The tool is held in a holder, supported on a clapper, in the head at the forward end of a ram. The ram reciprocates in a straight line, while the table, carrying the vise and work, feeds transversely on each return stroke. The clapper which carries the tool post is hinged near its top. On the cutting stroke the tool forces the clapper against its rigid seat; on the return stroke it swings outward about its hinge, as the tool is dragged back over the work, thereby relieving the cutting edge of excessive wear and reducing danger of chipping.

Shapers may be classified as horizontal or vertical (slotters), according to whether the ram operates horizontally or vertically, or they may be classed as plain or utility shapers for general light work and standard, heavy-duty, and production shapers. Most modern shapers are driven by self-contained motors, and the table has both rapid traverse and power feed, horizontally and vertically.

The planer was developed to machine flat surfaces on small or large work, too large for the shaper. The work to be machined is held in a vise or fixture bolted to the table, or it may be clamped directly to the table. The table is reciprocated past the cutting tools as the tools are fed horizontally, vertically, or at an angle for each stroke. The tools are held in a clapper box on a swiveling head carried on a saddle mounted on a horizontal rail. The

head is fed horizontally on the rail. Sometimes two heads are provided on the rail, and a third is mounted on the face of the housing. Large planers may take work 6–8 ft. in section and up to 30–40 ft. in length.

Gear-Cutting Machines.—There are six types of gear-cutting machines. For a composite tooth form a standard knee-type miller with dividing head is used for jobbing work. For large quantities

FIG. 6.—BASIC MACHINE-TOOL OPERATIONS: MILLING

of these gears a special production miller is used which automatically repositions the gear blank after each tooth is cut. The cutter has the approximate shape of the generated space between two teeth. This process is nongenerating and requires eight form cutters for each pitch for all gear teeth. The gear planer uses a cutter in the form of a short rack which cuts on its end as it is reciprocated across the face of the gear blank while the gear blank rolls with it, similar to a gear meshing with a rack. The gear shaper uses a disk-type cutter of the shape of a finished gear. It cuts on its end while reciprocated across the face of the blank as the two are rolled in unison. The gear-hobbing machine uses a cutter or hob consisting of a series of rack teeth arranged in a helix around the periphery of a cylinder. As the hob rotates continuously in unison with the blank to provide the generating action, it is fed across the face of the blank. The teeth of straight-tooth bevel gears are generated but, because of the tapered form, a special type of machine is needed to cause the single-tooth cutters of the rack shape to reciprocate along the cone of the pitch surface. Lastly, the spiral-bevel or hypoid-gear generator uses a cutter with single teeth of rack shape, arranged in a circle on the end of a disk, somewhat like those of a face mill. As the cutter is fed into the proper depth, it is rolled with the bevel-type gear blank to create the generating motion.

For precision gears, tooth profiles may be refinished, particularly after hardening, by special grinding or lapping machines, or by shaving. The gear-shaving machine runs the cutter and work-gear together under pressure with their axes slightly crossed, similar to the arrangement for lapping. The cutter of hardened steel is provided with multiple radial slots to form cutting edges on the tooth face. These have a side-sliding motion on the gear tooth to remove thin chips. (See also GEARS.)

Metal-Forming Machine Tools.—This large class includes machines used to shear, bend, draw, squeeze, coin, upset, swage, circle-cut, flange, forge, press, hammer, horn, and wire. In all these machines a movable ram works against an anvil. Power to the ram may be furnished by gravity; mechanically by a crank, cam, toggle, or knuckle joint; or through hydraulic or pneumatic systems. The machines may have one, two, or three rams on moving slides. The two-ram machine may blank and draw a part; the three-ram may blank with one ram, hold with the second, and form with the third. Dies, usually made in mating pairs, are an integral part of the equipment. One member of the pair is mounted on the fixed bed, or platen, of the press, and the other is attached to the lower end of the moving ram.

Flat sheets or plate stock are cut by squaring shears using a shearing action developed between a pair of straight cutting blades. The shearing action, called blanking, is employed also to cut a variety of shapes from a flat sheet. The press brake, similar to the shear, is equipped with either punching dies or bending dies to form edges.

Power presses are made in a large variety of types and sizes, some weighing nearly 1,000,000 lb. The dies used in stamping presses may also be very complicated. Cutting dies are made either plain, for one operation of punching or blanking; progressive, for performing successive operations; compound, to pierce and blank; multiple, and combination, to cut and shape. Shaping dies may be classified as bending, curling, drawing, or compression dies.

Presses are made automatic and safe in operation by feeding strip metal from rolls to the dies and removing the scrap from the dies. Some presses are combined to pass the parts automatically from one to another for a series of operations.

Forging machines are also made in several types, some vertical, some horizontal. They range from the small upsetting machine that makes balls, screw blanks, springs, etc., from wire, to the large steam forging hammer for making drop forgings in dies and the large hydraulic presses which forge parts weighing many tons.

Auxiliary Equipment.—Numerical control, using punched cards or tape or magnetic tape to direct the path or locations and rates of cutting, is being applied to many machines. It has great economic value in obtaining high accuracy and uniformity of com-

plicated parts. As with any costly equipment, the time for checking and adjustment should be minimized. Cutting tools dimensionally preset or automatically adjusted in response to measuring devices built into the machine are essential to numerical control and desirable in any high-production machine. Similarly, the time and effort of handling, inspecting, and sorting workpieces is minimized by all sorts of hoists, mechanical positioners, storage and delivery conveyors, and easily read integrated inspection devices which might mark the piece or select its route through the handling system.

New processes for materials difficult to machine by conventional methods are rapidly developing. In some instances, processes using such sophisticated "tools" as laser beams provide the only solution. These unconventional (nonmachining) processes are described in the article METALWORKING PROCESSES.

MACH NUMBER, named for the Austrian scientist Ernst Mach (q.v.), is the ratio of a flow velocity to a velocity of sound (see SOUND: *Analysis of Acoustic Propagation*.) The speed of sound varies with temperature, and thus with altitude, but at sea level is approximately 760 m.p.h. The most commonly used Mach number is the "free-stream Mach number" defined for the flow about a body immersed in a uniform free stream. This number is the ratio of the uniform velocity in the free stream to the sound speed there. It is the same as the "flight Mach number," the ratio of the velocity of a vehicle flying in an atmosphere to the sound speed in the atmosphere. The free-stream Mach number is the most important parameter characterizing the flow field and aerodynamic forces. A flow is termed "incompressible" if this number is negligible; "subsonic" if it is not small but significantly less than one, as 0.80; "transonic" if it is approximately one; "supersonic" if it is significantly greater than one, as 1.75; and "hypersonic" if it is much greater than one.

The "local Mach number" is the ratio of the local flow velocity in a steady flow of a gas to the local sound speed. If this number is less than one the partial differential equations governing the flow field are locally of elliptic type. If this number is greater than one the equations are locally of hyperbolic type. If the flow is sufficiently close to a uniform flow, the local Mach number may be approximated at each point by the constant free-stream Mach number, and the differential equations of motion by linear ones.

(W. D. Hs.)

MACHRAY, ROBERT (1831–1904), first primate of the Church of England in Canada, was born at Aberdeen, Scot., on May 17, 1831, and educated at Aberdeen and Cambridge universities. He was ordained in 1855 and in 1865 was appointed to be the second bishop of Rupert's Land. For the next 40 years he was undoubtedly the outstanding churchman in Canada. When in 1877 the University of Manitoba was constituted, the government appointed Machray to be its chancellor, a post he held until his death. His first diocesan conference was attended by 10 priests and 18 lay delegates; at his death in 1904 the province over which he presided as metropolitan consisted of nine fully constituted dioceses. In 1889 proposals were made for the constitution of the Church of England in Canada as a fully independent church within the fellowship of the Anglican communion. This was a natural step in view of the unification of the country through improved communications and its progress in the political field toward the status of an independent nation. On Sept. 18, 1893, Machray was unanimously elected to be the first primate of the church. He died on March 9, 1904, at Winnipeg, Man.

BIBLIOGRAPHY.—R. Machray, *Life of Robert Machray* (1909); H. H. Walsh, *The Christian Church in Canada* (1956); P. Carrington, *The Anglican Church in Canada* (1963). (S. C. N.)

MACHYNLLETH, an urban district and market town in the Montgomeryshire parliamentary division of Wales, 10 mi. E.N.E. of Aberdovey and the coast and 40 mi. W.N.W. of Montgomery by road. Pop. (1961) 1,904. Lying in the Dyfi (Dovey) valley on

the threshold of mountainous country, it is a centre for anglers and for tourists. In 1291 a charter was obtained which established the Wednesday market and the two annual fairs. Owen Glendower held a parliament at Machynlleth in 1404, allegedly in a house (now the town institute) opposite Plâs Machynlleth, a manor with a spacious park given to the town by Lord London-derry. The woolen and tanning industries flourished in the 19th century.

MACIÀ, FRANCESC (1859–1933), Catalan nationalist, a leading figure in the struggle for home rule for Catalonia in Spain, was born at Villanueva y Geltrú on Oct. 21, 1859. He became a military engineer and rose to the rank of colonel. On a wave of regional enthusiasm aroused by his action against anti-Catalanist military demonstrators in 1905, he was elected to the *Cortes*. Thereafter he was prominent in the Catalan separatist movement, founding the *Estat Català* in 1922. Exiled under Primo de Rivera, he organized the unsuccessful *Prats de Molló* attempt to overthrow the government in 1926. When he returned to Spain after the fall of the dictatorship he created the coalition of Catalan left republican parties (*Esquerra Republicana*) that won the municipal elections of April 12, 1931. Two days later, before the republic was established in Madrid, he was acclaimed president of the Catalan republic. He compromised with Madrid over the status of Catalonia, and on Sept. 9, 1932, the constituent *cortes* passed the statute of autonomy. Macià, known as *Pavi* ("Grandfather"), became first president of what was called the *Generalitat* of Catalonia (see SPAIN: *History*). He died in Barcelona on Dec. 25, 1933. (H. F. GR.)

MACÍAS (O NAMORADO) (fl. 1340–1370), the last of the Galician *trobadores*, is best known as the protagonist of a legend attributing his death to a lance wound at the hands of his lady's jealous husband. This story, fancifully derived from one of Macías' own poems and enriched by Arabic and other accretions, is a peninsular representative of the universal courtly tradition of the love martyr, and has been since the 15th century a favourite theme of Spanish writers, including, among many others, Lope de Vega and Mariano José de Larra (*qq.v.*). Macías' poems are preserved in the 15th century *Cancioneira de Baena*.

See H. A. Rennert, *Macías, o Namorado* (1900; Spanish trans. 1904; 2nd ed., 1941). (F. S. R.)

MCINTIRE, SAMUEL (1757–1811), U.S. architect and craftsman, known as "the architect of Salem," was born in Jan. 1757 in Salem, Mass. One of a family of substantial housewrights, he was at 23 already working for his chief patron, the merchant Elias Hasket Derby. The solid foursquare house he created for Jerathmeel Peirce, with details derived from an English handbook, Batty Langley's *Treasury of Designs* (1740), was one of the finest houses of New England in the post-Revolutionary period. His academic style was exemplified in the Salem court house (1785; demolished 1839) and culminated in a competitive design of 1792 for the Capitol in Washington, based on plates in James Gibbs's *Book of Architecture* (1728). Charles Bulfinch meanwhile had introduced to New England the style of Robert Adam, with its attenuated proportions, its classic ornaments often cast in composition and its greater variety of forms of space, with rooms oval and circular. McIntire studied Bulfinch's first houses, and from 1793 he adopted their style and carved many of their chief ornaments. Bulfinch made the first designs, and McIntire the final ones, for the lavishly decorated Derby mansion begun in 1794 (destroyed in 1815). In numerous houses McIntire placed his stamp on the town in the prosperous early years of the 19th century.

His carvings included busts, reliefs and the decorations of ships and furniture. Sofas, chairs and other pieces he carved with his typical eagles, baskets of fruit, draperies and pendants of the greatest delicacy. Over 100 pieces survive, constituting the most impressive body of U.S. furniture of the Sheraton style. Works of this modest craftsman and sober citizen, who never traveled more than a few miles from his native town, adorn the leading U.S. art museums.

McIntire died in Salem on Feb. 6, 1811.

MACINTOSH, CHARLES (1766–1843), Scottish industrial chemist after whom "macintosh" raincoats were named, was born in Glasgow on Dec. 29, 1766, and died near Glasgow on July 25, 1843. He improved the manufacture of dyes, mordants and iron, and he devised the process for making dry bleaching powder. He applied the solubility of india rubber in naphtha to cement together two thicknesses of rubber and so make waterproof fabrics.

See George Macintosh, *Biographical Memoir of . . . Charles Macintosh*, F.R.S. (1847). (D. McK.)

MACIP (MASIP), VICENTE JUAN (also called JUAN DE JUANES or JOANES) (?1523 or earlier–1579), Spanish artist, one of the chief Valencian painters of the third quarter of the 16th century, was the son of another Valencian painter, Vicente Juan Macip the elder. Most of his work was done in Valencia, and he died in nearby Bocairente on Dec. 21, 1579. He may have studied in Italy, since his style is largely a provincial adaptation of the manner of Leonardo da Vinci's followers, with the addition of some Florentine motifs. But his paintings also display strong Flemish influence, and the Italian elements may have been derived from the works of italianizing Flemings, which abounded in Spain and which were probably also the source of Macip's somewhat grotesque realism.

Almost all Macip pictures are religious; the "Last Supper" and the scenes from the life of St. Stephen, in the Prado museum, Madrid, are among the best known, and he painted many versions of Christ as *Salvator Mundi*. (N. Mn.)

MACK, CONNIE (CORNELIUS MCGILLICUDDY) (1862–1956), U.S. baseball manager, the "grand old man" of major league baseball in the first half of the 20th century, managed the Philadelphia Athletics from 1901 to 1950, during which period they won the American league pennant nine times and the world series five times (1910, 1911, 1913, 1929 and 1930). Born in East Brookfield, Mass., on Dec. 23, 1862, and christened Cornelius McGillicuddy, he shortened his name so that it would fit on a scoreboard. A catcher, Mack entered organized baseball with his home town team in 1883, moving the next year to Meriden, Conn., then to Hartford, Conn. (1885). With Washington, D.C. (1886–89), Buffalo, N.Y. (1890) and Pittsburgh (1891–96), he played 695 games with a lifetime batting average of .252.

Mack caught in 664 major league games and occasionally played first base or in the outfield. He was catcher-manager of the Milwaukee, Wis., club of the Western association from 1897 to 1901, and in 1901 became manager and part owner of the Athletics.

CULVER PICTURES, INC.

CONNIE MACK (RIGHT) AND JOHN MCGRAW MEET PRIOR TO THE FIRST SANCTIONED WORLD SERIES IN 1905

and helped establish the American league (see *BASEBALL: Later History*). His team won the American League pennant in 1905 and participated in the first sanctioned World Series (defeated by the Giants of John McGraw, 4 games to 1). He was elected to baseball's Hall of Fame in 1939, and retired in 1951. He died in Philadelphia on Feb. 8, 1956. (J. D. McC.; X.)

MACKAY, CLARENCE HUNGERFORD (1874–1938), U.S. capitalist and philanthropist, who as president of the Mackay system of telegraphs and cables directed the completion of the first trans-Pacific cable between the United States and the far east in 1904, was born at San Francisco, Calif., on April 17, 1874.

The foundations for his career were laid by his father, John William Mackay (1831–1902), California and Nevada miner, born in Dublin, Ire., Nov. 28, 1831, whose parents brought him to New York in 1840. When he was 21 he sailed for California to try his luck in the gold fields. Working with pick and shovel in the Sierra Nevada mountains, and later in western Nevada, John Mackay learned mining engineering and geology through experience. In 1873, he and his partners, James C. Flood, William O'Brien and James G. Fair, discovered the big bonanza of the Comstock lode that yielded approximately \$120,000,000 in the next five years. With James Gordon Bennett, Mackay organized the Commercial Cable company in 1883, succeeded in breaking the communications monopoly of the Western Union Telegraph company directed by Jay Gould and established the competing Postal Telegraph company.

In 1907, the company, of which Clarence Mackay had become president after his father's death, placed a cable in service between New York and Cuba and later established cable communication with southern Europe by way of the Azores and with northern Europe through Ireland. He was the first, in 1928, to combine radio cables and telegraphs under one management.

As a patron of the arts and education, Mackay served as chairman of the board of the Philharmonic Symphony society of New York, trustee of the Metropolitan Museum of Art and director of the Metropolitan Opera company. In memory of his father, he and his mother presented the University of Nevada with the Mackay school of mines. This and a subsequent series of gifts to that university totaled more than \$1,500,000.

Mackay was a member of the French Legion of Honour, and in 1931 Pope Pius XI made him a Knight of Malta, the highest Catholic lay honour. He died in New York city Nov. 12, 1938. (W. T. J.)

McKAY, DONALD (1810–1880), U.S. shipbuilder and naval architect, builder of the largest and fastest clipper ships, was born Sept. 4, 1810, in Nova Scotia. He moved to New York city in 1827 and was apprenticed ship carpenter to Isaac Webb. His adventure completed, he worked at this trade in New York and Newburyport, Mass. In 1845 McKay established his own shipyard at East Boston, Mass., and there designed and built the ships that gave him his reputation. His first, the "Stag Hound," launched in 1850, was followed by many others. His "Lightning" sailed 436 actual miles in 24 hours, at times reaching a speed of 21 knots. The "Great Republic" registered 4,555 tons when completed and was the largest clipper ship built.

By 1855 the demand for these specialized ships was over and McKay closed his yard. In 1863 he equipped the yard to build iron ships and built several vessels for the U.S. navy, one of which was the monitor "Nauasett"; but he was not financially successful in this work. His last sailing ship, the "Glory of the Seas," built in 1869, lasted until 1923. McKay died at Hamilton, Mass., on Sept. 20, 1880. See also *CLIPPER SHIPS*. (M. R. D.)

MACKAY, a seaport on the northeast coast of Queensland, Austr., 600 mi. N. of Brisbane by rail. Pop. (1961) 16,809. The city is situated on the Pioneer river, and the district is bounded by the Clarke and Leichhardt ranges, the highest peak being Mt. Rymple (4,190 ft.). The climate, which is moderate generally, is very good during the main tourist season, from April to October. The average annual rainfall is 70 in. The chief industry is the manufacture of sugar, and others are dairying, sawmilling and the production of power alcohol (ethyl alcohol suitable for use as a fuel in internal-combustion engines), industrial methylated spirits

and other sugar by-products. Large deposits of coal exist in the hinterland area, and copper mining is undertaken in a small way. Tropical fruits (bananas, pawpaws and pineapples) are grown. A sugar research institute was established there in 1953.

Mackay has a deepwater artificial harbour, about three miles north of the city. It is served by daily air and rail links north and south.

MacKAYE, PERCY (1875–1956), U.S. poet and dramatist, an advocate of civic theatre and a significant figure in the development of the modern pageant in the U.S. (see *PAGEANT*). The son of Steele MacKaye (q.v.), he was born in New York city on March 16, 1875. After graduating from Harvard in 1897, he traveled and studied abroad (1898–1900).

After his return to the United States, MacKaye lectured in schools and colleges and wrote *The Civic Theatre* (1912), advocating amateur community theatricals. The pageants he wrote encouraged community participation. They included *The Canterbury Pilgrims*, produced at Gloucester, Mass., in 1909 with a cast of 1,500, and *The Pageant and Masque of St. Louis* (Thomas Wood Stevens, co-author), performed in St. Louis, Mo., in 1914 with 7,500 participants. In 1948 MacKaye received the Academy of American Poets fellowship award for his cycle of four plays, *The Mystery of Hamlet, King of Denmark* (1945). He died at Cornish, N.H., on Aug. 31, 1956.

MacKaye's many other works include poetry, plays, essays and a biography of his father (1927).

MacKAYE, (JAMES MORRISON) STEELE (1842–1894), U.S. playwright, actor, theatre manager and inventor, a brilliant man of many talents who was, perhaps, the closest approximation to the Renaissance man produced by the United States in the 19th century. He was born in Buffalo, N.Y., June 6, 1842. In his youth he studied painting with Hunt, Inness and Troyon. A pupil of Delsarte and Régnier, he was the first American to act Hamlet in London (1873). At Harvard, Cornell and elsewhere, he lectured on the philosophy of aesthetics. In New York city he founded the St. James, Madison Square and Lyceum theatres.

MacKaye wrote 30 plays, including *Hazel Kirke* (performed many thousands of times), *Paul Kaurvar*, *Money Mad*, etc., acting in them in 17 different roles. He organized the first school of expression (which later became the American Academy of Dramatic Art) and originated "harmonic gymnastics"; initiated overhead lighting (1874); invented the first moving "double stage" (1879); and invented folding theatre seats. In all, he patented over 100 theatrical inventions.

At the Chicago World's fair of 1893, MacKaye projected the world's largest theatre, his Spectatorium (seating 12,000, with 25 moving stages), revolutionizing stage production and anticipating motion pictures. Financial difficulties prevented completion of the theatre—the first production was to be *The World Finder*, a saga of Columbus, for which Dvorak composed his *New World Symphony*—but a scale model was later successfully demonstrated.

Though he is best remembered for *Hazel Kirke*, MacKaye's chief importance actually lies in the area of stage production and in his influence toward higher professional standards and ethics in the theatre. He died at Timpas, Colo., Feb. 25, 1894.

See Percy MacKaye, *Epoch: the Life of Steele MacKaye*, 2 vol. (1927). (S. W. H.)

MACKE, AUGUST (1887–1914), German painter, one of the leaders of the Blue Rider school, was born on Jan. 3, 1887, at Meschede, Westphalia. His youth was spent in Cologne and Bonn, and he studied art from 1904, at the Düsseldorf academy and later in Berlin with Lovis Corinth. He was influenced, particularly in his earlier work, by the older Impressionists, Cézanne, Matisse, Picasso and the Cubists. He also visited Paris, Holland and Italy. The period of his independent creation embraces the years 1909–14.

With Kandinsky, Jawlensky and Marc, Macke was one of the most important representatives of the Blue Rider group of painters from which Expressionism in Germany originated (see *PAINTING: Expressionism and the German School: Der Blaue Reiter*). His art combines the tradition of French painting, its sense of the

grace of movement and atmosphere in landscape painting, with the cosmic sentiment of German art, without losing itself in the subtle and problematical. A journey to Tunis in the spring of 1914 inspired some of his most beautiful pictures.

Macke was killed in World War I at Perthes-les-Hurlus, Champagne, on Sept. 26, 1914.

McKEESPORT, a city in Allegheny county, southwestern Pennsylvania, U.S. Approximately 10 mi. S.E. of Pittsburgh's "golden triangle," the city was founded at the junction of the Monongahela and Youghiogheny rivers. The former has long been an important avenue for the movement of coal and steel, essential elements in the industrial complex of the Pittsburgh (*q.v.*) standard metropolitan statistical area, of which McKeesport is a part. In the early 1960s about half of the community's working force was engaged in steel production.

The first settlement was made about 1755 by David McKee, who operated a ferry there, and the town was platted in 1795 by his son John. It did not develop appreciably until the basic ingredients of the U.S. steel industry (coal, iron and railroads) had progressed in the late 19th century. Coal mining in the area began about 1830. The G. C. Murphy chain of variety stores originated there in 1896. McKeesport was incorporated as a borough in 1842 and chartered as a city in 1890. It was a centre of dissident activity during the Whisky insurrection (*q.v.*) in 1794.

For comparative population figures *see* table in PENNSYLVANIA: *Population*.

(P. R. J.)

McKEES ROCKS, a borough of Allegheny county, Pa., U.S., on the Ohio river, 3 mi. from downtown Pittsburgh (*q.v.*). Producing a variety of small iron and steel products, it is an integral part of Pittsburgh's industrial complex. As industry expanded, the population declined slowly from a peak of 18,116 in 1930. Through an extensive rebuilding program launched in 1954, McKees Rocks was among the first suburbs to share in Pittsburgh's renaissance.

The first permanent homes in the area were built near a 100-ft. cliff overlooking the Ohio river, shortly after Pontiac's conspiracy of 1763. The cliff, later cut away for a railroad bed, was the site of an Indian burial mound. The borough, which was incorporated in 1892, was named for the imposing rock formations along the river and for Alexander McKee, a pioneer settler. For comparative population figures *see* table in PENNSYLVANIA: *Population*.

McKENNA, REGINALD (1863–1943), English statesman noted for his naval construction program before World War I, was born in London on July 6, 1863, the fifth son of W. C. McKenna, a civil servant. He was educated abroad, at King's College school, London, and at Trinity hall, Cambridge, where he studied mathematics. In 1895 he entered parliament as Liberal member for North Monmouthshire. He made a name for himself by a well-informed attack on one of Austen Chamberlain's budgets and when his party took office in 1905, McKenna became financial secretary to the treasury, entering the cabinet as president of the board of education in 1907. H. H. Asquith made him first lord of the admiralty in 1908, where he supported a full program of naval construction against the pacifist wing of the cabinet. The continuance of Britain's lead in battleships down to the outbreak of World War I was thus in part his achievement. In 1911 acute differences with Lord Haldane, the war minister, over the roles of the navy and army in war led to his changing offices with the home secretary, Winston Churchill. McKenna became chancellor of the exchequer in May 1915 and was responsible for two wartime budgets, a task well suited to his cool, statistical mind. At the end of 1916, Lloyd George, whom McKenna disliked, succeeded Asquith as prime minister. McKenna at once resigned. He lost his seat in 1918 and became chairman of the Midland bank in 1919. Bonar Law offered him the chancellorship of the exchequer in 1922 but McKenna, though in sympathy with the Conservatives, declined. A similar offer was made by Stanley Baldwin in 1923, and this he would have accepted, had it been possible to find him a safe seat. He never returned to politics and remained chairman of the bank till his death on Sept. 6, 1943.

(R. N. W. B.)

MACKENNAL, ALEXANDER (1835–1904), English Congregational minister prominent in the Free Church federation, was born at Truro in Cornwall, on Jan. 14, 1835, the son of Patrick Mackennal, a Scot, who had settled in Cornwall. In 1848 the family moved to London, and at 16 Mackennal went to Glasgow university. He entered the Congregational ministry in 1858, and from 1877 to his death was pastor of the Congregational church at Bowdon, Cheshire. In 1887 he was chairman of the Congregational union. In 1892 Mackennal became associated with a movement for free church federation which developed out of a series of meetings held to discuss the question of home reunion. Out of this grew the Free Church federation, of which Mackennal was secretary for six years. Mackennal was a lifelong advocate of international peace and made a remarkable declaration as to the Christian standard of national action when the Free Church federation met at Leeds during the South African War in 1900. He died at Highgate, London, on June 23, 1904.

See D. Macfadyen, *Life and Letters of Alexander Mackennal* (1905).

MACKENSEN, AUGUST VON (1849–1945), German field marshal, one of the most successful commanders in World War I, was born at Haus Leiniz in the Wittenberg district of Saxony on Dec. 6, 1849, the son of a land agent. He joined the 2nd Death's Head hussars in 1869 and served in the Franco-German War of 1870–71 as a regimental officer. Appointed to the general staff in 1882, he accompanied the German emperor William II on his journey to Palestine in 1898. In 1908 he was given command of the XVII corps on the Vistula. Early in World War I he commanded the 9th army on the eastern front and was successful against the Russians at Kutno, Lodz and Lowicz. He took command of the combined German-Austrian 11th army in western Galicia in April 1915 and, ably assisted by his chief of staff, Hans von Seeckt, achieved the great German breakthrough in the Gorlice-Tarnów area. He was rewarded by promotion to field marshal on June 20, 1915. This was the beginning of a run of victories for Mackensen: the defeat of the Russians at Bres-Litovsk and at Pinsk (Aug.–Sept. 1915), the overrunning of Serbia (Oct.–Nov. 1915) and the occupation of Rumania (1916–17).

After the armistice of Nov. 1918 Mackensen was interned by the French until Dec. 1919. He retired from the army in 1920 and was made a state counselor in 1933. He died near Celle on Nov. 8, 1945. His *Briefe und Aufzeichnungen aus Krieg und Frieden* was published in 1938.

(C. N. B.)

MACKENZIE, SIR ALEXANDER (1764–1820), North American explorer, was born in 1764 at Stornoway, Island of Lewis, Scot. Emigrating to North America, he entered a Montreal trading firm in 1779 which in 1787 amalgamated with the Northwest Fur company, the recently established rival to the Hudson's Bay company. In 1788 Mackenzie and his cousin Rod-erick set up on Lake Athabasca the trading post Fort Chipewyan. This was the starting point of Mackenzie's expedition in 1789 to discover the water passage believed to link the Great Slave lake with the Northern ocean. He followed the river now named after him to its delta in 69° N. on the Arctic ocean, completing, on his return to Fort Chipewyan, a journey of 2,990 mi. in 120 days. After a visit to England he made his second expedition from Fort Chipewyan, crossing the Rocky mountains in 1793 to reach the Pacific coast at Dean channel in 52° 21' N., 128° W., and returning by the same route, to accomplish the first crossing of the American continent to the north of Mexico. In 1808 he settled in Scotland, where he died at Moulinearn near Pitlochry on March 11, 1820.

See his *Voyages from Montreal . . . to the Frozen and Pacific Oceans* (1801); M. S. Wade, *Mackenzie of Canada* (1927).

(H. M. Ws.)

MACKENZIE, ALEXANDER (1822–1892), prime minister of Canada, 1873–78, was born in Perthshire, Scot., on Jan. 28, 1822. He emigrated to Upper Canada (Ontario) in 1842 and eventually became a building contractor at Sarnia. Through his interest in political reform, he met George Brown, editor of the *Toronto Globe* and leader of the Reform party. Their friendship grew while Mackenzie was editor (1852–54) of the *Reform London Shield*, and after Mackenzie's election to the legislative assembly of Canada in 1861 they worked in close association. Both supported the confederation movement in 1864.

Mackenzie remained in politics after Brown's retirement. He was elected for Lambton to the first dominion house of commons in 1867 and soon became leader of the opposition. He also sat in the legislative assembly of Ontario in 1871, holding the position of provincial treasurer until dual representation was abolished in 1872. When the Pacific railway scandal caused the defeat of Sir John A. Macdonald's government in 1873, he became prime minister and leader of the first Liberal administration. As a tactician, he lacked Macdonald's skill and found it difficult to construct a strong party.

The great depression of the 1870s multiplied his difficulties. Although influential members of the Liberal party were opposed to the commitment, his government had inherited a pledge that a railway would be built to the Pacific by 1881. As his own minister of public works, Mackenzie decided to build only short lines of track, making whatever use he could of stretches of water and U.S. lines. British Columbia became restive at the delay and threatened to secede from the confederation. Other ventures were unsuccessful: he failed to revive reciprocity with the United States in 1874. The most constructive work of his administration was accomplished by his minister of justice, Edward Blake, who succeeded in having the supreme court of Canada established in 1875 and the powers of the governor general clarified in 1876.

In the election of 1878, Macdonald caught the popular imagination by advocating a protective tariff. Mackenzie was defeated. He remained leader of the opposition until 1880, when he retired in favour of Blake. He sat in the house of commons until his death at Toronto on April 17, 1892.

See Dale C. Thomson, *Alexander Mackenzie, Clear Grit* (1960).
(M. A. O.)

MACKENZIE, SIR ALEXANDER CAMPBELL (1847–1935), Scottish composer, was born in Edinburgh on Aug. 22, 1847. At the age of ten he was sent to study music in Germany at Sondershausen, where he also played the violin in the ducal orchestra. Returning to Britain, he continued his studies at the Royal Academy of Music, London. Then followed some years in Edinburgh as composer, conductor and violinist, until, encouraged by Hans von Bülow, he settled in Florence to devote himself to composition. The cantatas *The Bride* (1881) and *Jason* (1882) belong to this time, as do his first two operas, *Colomba* (1883) and *The Troubadour* (1886). From 1888 to 1924 he was principal of the Royal Academy of Music, of which he improved the economy and the teaching methods. In London he was also active as a conductor and lecturer. Together with Sir Hubert Parry and Sir Charles Stanford, he was associated with the renaissance of British music at the end of the 19th century. He was knighted in 1895. Among other notable works by him were an oratorio, *The Rose of Sharon*; a *Scottish Concerto* for piano; three Scottish rhapsodies; and the overture *Britannia*. He died in London on April 28, 1935.

See A. C. Mackenzie, *A Musician's Narrative* (1927). (H. Ru.)

MACKENZIE, CHARLES FREDERICK (1825–1862), first Anglican bishop in central Africa, was born at Portmore, Peeblesshire, on April 10, 1825, and educated at Cambridge. In 1854 he accompanied Bishop J. W. Colenso to Natal as his archdeacon; he shared with his diocesan the view that African Christians should take part, on a basis of full equality, with white Christians, in all the affairs of the church. Ill health caused his return to England in 1859. In 1860 he was invited by the Universities mission to central Africa to become head of their projected mission in the Zambezi region. He was consecrated bishop on Jan. 1, 1861, in Cape Town cathedral—the first occasion in Anglican history on which a bishop was consecrated as a pioneer for an area in which as yet no church existed. The difficulties involved in establishing a mission in central Africa had been gravely underestimated. All the missionaries suffered from illness. They were badly served by those who should have helped them by maintaining communications and supplies. They compromised their position by becoming involved in the endless warfare of the local tribes. Then, while on a journey to meet Livingstone, Mackenzie fell ill and died on Jan. 31, 1862. He was a man of transparent and humble Christian devotion, but with hardly the strength and

prudence required in the leader of so hazardous a venture.

See H. Goodwin, *Memoir of Bishop Mackenzie*, 2nd ed. (1865); O. Chadwick, *Mackenzie's Grave* (1959).
(S. C. N.)

MACKENZIE, SIR EDWARD MONTAGUE COMPTON (1883–), a prolific and versatile English novelist, came from a well-known theatrical family and was born at West Hartlepool, on Jan. 17, 1883. Educated at St. Paul's school, London, and Magdalen college, Oxford, he turned from the stage to literature in his late twenties. His first success, *Sinister Street*, two volumes (1913–14), describes growing up, and its second volume remains the most successful novel of undergraduate life at Oxford. World War I took Mackenzie to intelligence work in the eastern Mediterranean, about which he wrote racy volumes of memoirs: one, *Greek Memories* (1932), had to be revised after a prosecution under the Official Secrets act. Two of his best satirical novels, *Vestal Fire* (1927) and *Extraordinary Women* (1928), set in Capri, show the influence of his friend Norman Douglas. After 1928 he lived in Scotland; he was a keen Scottish nationalist, and his broadly comic *Whisky Galore* (1947) is one of his later light-hearted tales with a west highland setting. Compton Mackenzie, as he is generally known, was knighted in 1952. The range of his output, some of it topical or ephemeral, has made it difficult to evaluate his work and it may be said that he has never fulfilled the promise that Henry James saw in him. But his writing has a rich, full life behind it, and shows verve, wit and unquenchable feeling for romance.

(G. S. F.)

MACKENZIE, SIR GEORGE (1636–1691), of Rosehaugh, Scottish lawyer noted as a prosecutor of covenanters and founder of the Advocates' library, was born at Dundee in 1636. He was educated at the grammar school there and also at the universities of Aberdeen, St. Andrews and Bourges, and was called to the Scottish bar in 1659. As king's advocate after Aug. 1677, he conducted a vigorous prosecution of covenanters for their violation of statutes, earning for himself an unenviable distinction as "the bloody Mackenzie." He boasted (1680) that he had never lost a case for the crown. His methods, however, were questionable, notably in the prosecutions of the earl of Argyll and James Mitchell. As dean of the faculty of advocates, he was the main promoter of the Advocates' library, now the National Library of Scotland, founded in 1682. His refusal to concur in the measures for dispensing with the laws against Catholics led to his removal from office in May 1686, but he was reinstated in Feb. 1688. At the Revolution of 1688, he was one of the five members of the convention who opposed the decision that James II had forfeited the crown. William III refused to declare him incapacitated for holding any public office, but when the death of John Graham, Viscount Dundee, in July 1689 had destroyed the hopes of his party in Scotland, Mackenzie withdrew to England, and died at Westminster on May 8, 1691.

Mackenzie wrote widely on religious issues and moral philosophy; he also wrote an early piece of fiction, *Aretina* (1661), but the bulk of his writing was concerned with the law. In *Jus Regium* (1684), and in other writings, Mackenzie appears as an advocate of the highest doctrines of prerogative, a supporter of hereditary monarchy, a critic of intolerance and inhumanity, but a firm believer in enforcing obedience to the law in what he regarded as nonessentials. His *Vindication of the Government of Scotland During the reign of Charles II* (1691) is valuable as contemporary history. His collected *Works* were published at Edinburgh (2 vol., 1716–22) and *Memoirs of the Affairs of Scotland From the Restoration of King Charles II*, from previously unpublished sources, in 1821.

See A. Lang, *Sir George Mackenzie of Rosehaugh* (1909).

(Gn. D.)

MACKENZIE, HENRY (1745–1831), Scottish novelist and miscellaneous writer, and the leading literary figure in Scotland during the last 30 years of the 18th century, was born in Edinburgh on Aug. 26, 1745, the son of a doctor. On both sides he was descended from Highland gentlefolk and consequently throughout his adult life he was a convinced Tory. Educated at the high school and the University of Edinburgh, he wrote much verse during his adolescence, most notably two poems in the style

of the traditional Scottish ballads which are equal to anything in the same manner written by Sir Walter Scott about 30 years later. But after becoming an attorney in 1765, Mackenzie went to study exchequer law in London, where he lost touch with Scottish traditions and turned to southern styles, imitating the "novel of sensibility" as written by Laurence Sterne. His *The Man of Feeling* (begun 1767, published 1771) was a best-seller, but the cool clarity of Mackenzie's style scarcely redeems the lachrymose mawkishness of plot and characterization. His other novels in the same mode were *The Man of the World* (1773) and *Julia de Roubigné* (1777). After settling in Scotland as an exchequer attorney in 1768, Mackenzie wrote for the Edinburgh stage a successful tragedy, *The Prince of Tunis* (1773), and although his other plays were failures he retained his interest in the theatre, encouraging the work of Joanna Baillie.

Established as the luminary of Scottish literary circles, Mackenzie edited two periodicals, *The Mirror* (1779-80) and *The Lounger* (1785-87), his own contributions to which earned him doubtful praise as "the Scottish Addison." When he writes on Scottish scenes and characters, however, his essays are more than merely successful pastiche, and he pioneered the appreciation of Burns with an early review of the Kilmarnock edition (1786); later, his papers on German literature encouraged Scott to attempt his first translations of German verse. In 1783 Mackenzie helped to found the Royal Society of Edinburgh, and in 1784 the Highland society, for which he edited a report on the authenticity of "Ossian's" poems (1805). During the troubles at the outbreak of the French Revolution and the Revolutionary War, Mackenzie wrote much anonymous political journalism for the Tory party, some of which he later regretted; his reward was his appointment, in 1799, as comptroller of taxes in Scotland. The authorized edition of his *Works* (8 vol.) was published in 1808, and his position as patriarch of Scottish letters was recognized when Scott made him the dedicatee of *Waverley* (1814). Having long outgrown sentimentalism, Mackenzie provided witty and incisive sketches of 18th-century Scotland in his *Life of John Home* (1822) and in his *Anecdotes and Egotisms* (written c. 1824-26, but unpublished until 1927). He died on Jan. 14, 1831.

See *The Anecdotes and Egotisms of Henry Mackenzie* ed. by H. W. Thompson (1927); H. W. Thompson, *A Scottish Man of Feeling* (1931). (A. M. S.)

MACKENZIE, SIR MORELL (1837-1892), British physician, centre of a 19th-century *cause célèbre* over the death of the German emperor Frederick III (*q.v.*), was born at Leytonstone, Essex, on July 7, 1837. He studied at the London hospital, at Paris, Vienna and Budapest, where he learned the use of the newly invented laryngoscope under J. N. Czermak. In 1862 he took his degree and became a specialist in diseases of the throat. In 1863 he helped to found the Throat hospital in King street, Golden square, and became a leading authority.

In May 1887 Mackenzie was summoned to attend the German crown prince Frederick William, whose illness was difficult to diagnose. The German physicians who had attended the prince since the beginning of March had diagnosed his disease on May 18 as cancer of the throat; but Morell Mackenzie insisted (basing his opinion on a microscopic examination by R. Virchow of a portion of the tissue) that the disease was not demonstrably cancerous, that an operation for the extirpation of the larynx (planned for May 21) was unjustifiable, and that the growth might well be benign and therefore curable by other treatment. Mackenzie's opinion was followed; he was knighted in Sept. 1887 for his services, and decorated with the Grand Cross of the Hohenzollern Order. In November, however, it was ultimately admitted that the disease really was cancer; though Mackenzie, with very questionable judgment, more than hinted that it had become malignant since his first examination, in consequence of the irritating effect of the treatment by the German doctors. The crown prince became emperor, as Frederick III, on March 9, 1888, and died on June 15. A violent quarrel raged between Mackenzie and the German medical world. The German doctors published an account of the illness, *Die Krankheit Kaiser Friedrichs III* (1888), to which Mackenzie replied by a work entitled *The Fatal Illness of Frederick the Noble*

(1888), the publication of which caused him to be censured by the Royal College of Surgeons. Mackenzie died in London on Feb. 3, 1892, leaving several books on laryngoscopy and diseases of the throat.

See R. S. Stevenson, *Morell Mackenzie: the Story of a Victorian Tragedy* (1946, 1947).

MACKENZIE, WILLIAM LYON (1795-1861), Canadian rebel, journalist and politician, led an armed band of farmers and mechanics against Toronto in 1837 in an unsuccessful attempt to end British colonial rule in Upper Canada. Several days after the rebels' defeat at the hands of the loyalist militia and Mackenzie's escape to the United States, he returned to set up a short-lived Canadian republic on Navy Island, in the Niagara river. Throughout 1838 Mackenzie's presence in the United States inspired a series of raids across the border that brought the United States and Britain to the brink of war. Along with Louis Joseph Papineau's rebellion in Lower Canada, Mackenzie's action eventually led to the British grant of responsible government in Canada in 1848, and to the beginnings of the modern commonwealth.

Mackenzie was born near Dundee in Scotland, and brought up on family pride, poverty and a good stiff dose of the Presbyterian catechism by his widowed mother. As a young man he read prodigiously, and was strongly influenced by the writings of the contemporary Scottish Whigs and Radicals. He was a wild-looking, wiry little man with a large head and high brow and restless piercing blue eyes. He had lost his hair from a fever and covered his baldness with a loose, flame-red wig.

Four years after his emigration to Upper Canada in 1820, Mackenzie founded a newspaper called the *Colonial Advocate*, and began attacking the political and economic privileges enjoyed by a ruling colonial oligarchy of merchants, land speculators, lawyers and churchmen known as the Family Compact. His newspaper's invective was so violent that a Tory majority in the colonial assembly, to which he had been elected in 1828, expelled him from the house six times, only to have him returned on all six occasions by the electors of York county. A Reform majority in the next assembly enabled Mackenzie to take his seat in 1834, the year in which he was also elected first mayor of the new city of Toronto (formerly York). The report of Mackenzie's committee on grievances in 1835 was a thorough exposure of the inadequacy of colonial rule and was taken very seriously by the British government. But in the colonial elections of 1836 lieutenant governor Sir Francis Bond Head and the Compact managed to convince the electorate, many of them newly arrived British immigrants, that Mackenzie was disloyal, and as a result he and several other Reformers lost their seats.

Mackenzie had occasionally talked rebellion before, but he now began to consider it seriously. He founded a more radical newspaper, the *Constitution*, on July 4, 1836, to express the ideas of Jacksonian democracy which he had espoused during the 1830s. A severe economic depression helped bring big crowds to the series of rural meetings he held in the summer of 1837. He drafted a constitution along U.S. lines in the autumn and made plans for an armed uprising. After the outbreak of Papineau's Lower Canadian rebellion, the hard core of Mackenzie's supporters assembled just north of Toronto. Insufficiently trained and organized, they scattered before the first loyalist attack.

The rebellion ultimately foundered on the rock of popular loyalty to the crown and British institutions. Mackenzie himself, after 12 years of exile, became thoroughly disillusioned with U.S. politics. He was finally pardoned and allowed to return to Canada in 1849, and in 1851 was elected to parliament. Just as in the 1830s, Mackenzie was an intelligent and hardworking committee chairman. And again his extreme independence and unswerving incorruptibility made him an embarrassment to many of his allies. Unlike the expansionist wing of the Reform (and later Liberal) party, he opposed the incorporation of banking, canal and railway companies that would develop the country at the price of profit and power for their owners. He clung to the Jeffersonian ideal of agrarian democracy and an industrialism of the small independent craftsman. In 1858 he resigned his seat in the house. He died in Toronto on Aug. 28, 1861.

Most of the causes Mackenzie fought for, from universal suffrage and free schools to a professional civil service, from sound banking to Canadian self-government, eventually triumphed. But at heart Mackenzie was a prophet and visionary whom no reform short of Utopia would have satisfied, and he pursued his vision with a single-minded, sometimes ludicrous, sometimes tragic heroism. After his death he became a patron saint of Canadian radicalism. Legends about him have been absorbed into the folklore of southwestern Ontario. His life had a deep and mysterious influence on his namesake and grandson, the Liberal prime minister W. L. M. King.

BIBLIOGRAPHY.—The *Life and Times* by his son-in-law, Charles Lindsey, 2 vol. (1862), while often biased and misleading, is an invaluable memoir. William Kilbourn's *The Firebrand* (1956), a brief biography built around the story of the 1837 rebellion, contains an extensive bibliography. See also Lillian Gates, "The Decided Policy of William Lyon Mackenzie," *Can. Hist. Rev.*, vol. xl, 185-208 (1959). (W. M. Kr.)

MACKENZIE, created in 1895 as the western district of the three divisions of the Northwest Territories of Canada, was named after the Mackenzie river. It was bounded on the east by the District of Keewatin (longitude 102° W.), on the west by Yukon Territory, on the south by Saskatchewan, Alberta and the north-east corner of British Columbia (latitude 60° N.) and on the north by the Arctic ocean. Area 527,490 sq.mi. Pop. (1961) 14,895; the most populous district of the Northwest Territories. This fact, together with the growing economic potential and the opening of all-weather transportation routes in the second half of the 20th century, prompted the movement to replace the District of Mackenzie with the Territory of Mackenzie, comprising the mainland of the Northwest Territories west of the 105th meridian and Banks, Victoria and several smaller islands.

Physiographically the district is characterized by the Mackenzie, Franklin and Richardson mountains, the northern extension of the Rockies, on the west; the Mackenzie lowlands containing the Mackenzie river and Great Bear and Great Slave lakes in the central area; and the western edge of the Canadian shield on the east. See NORTHWEST TERRITORIES.

MACKENZIE RIVER, a river of the Northwest Territories (q.v.), Canada, which discharges the waters of Great Slave lake into the Arctic ocean. Discovered and explored by Sir Alexander Mackenzie in 1789, it rises as the Finlay in north central British Columbia, flowing eastward to form the Peace (q.v.), which joins the discharge from Lake Athabasca as the Slave river and flows into Great Slave lake. From the Great Slave, the Mackenzie proper flows northwest for 1,100 mi. to empty into the Beaufort sea of the Arctic ocean near the Yukon border. The Mackenzie drains an area of 682,000 sq.mi., and is the longest river system in Canada. Ice-free from about the first week of June to the middle of October, the Mackenzie is navigable from its mouth to Great Slave lake. Connection with the railhead at Waterways, Alta., is made by way of the Slave and Athabasca (q.v.) rivers, with one 16-mi. portage from Fort Smith, N.W. Terr., to Fitzgerald, Alta. Boats also operate on the Liard river from Fort Nelson, B.C., to its junction with the Mackenzie at Fort Simpson and on the Peace from Peace River, Alta., to Fitzgerald except for the rapids near Fort Vermilion.

Settlements on the Mackenzie include Fort Providence, Wrigley, Fort Simpson, Fort Norman, Norman Wells, Fort Good Hope, Arctic Red River, Aklavik and Inuvik. Norman Wells is a petroleum centre, oil having been struck there in 1920.

The mouth of the Mackenzie, a lake-strewn delta measuring 110 mi. in length and 40 mi. in width, is noted for its muskrat catch.

(J. R. M.)

MACKEREL, a common name for many species of the family Scombridae, swift, carnivorous pelagic fishes found in tropical and temperate seas, characterized by a fusiform shape, a series of detached rays or finlets following the soft dorsal and anal fins, a slender caudal peduncle and a widely forked tail.

The common mackerel of the North Atlantic (*Scomber scombrus*) is distinguished from other scombrids by having the two dorsal fins separated by more than the length of the first (spinous) dorsal fin; two small keels on each side of the caudal

peduncle, but no median lateral keel; and no air bladder. It occurs on both sides of the North Atlantic from North Carolina to the Strait of Belle Isle and from the Black sea and the Mediterranean to Norway. Mackerel congregate in schools, according to size, swimming actively in the upper 25-30 fathoms from spring until mid-autumn, then descending to as deep as 100 fathoms for the winter. They feed on plankton, including crustaceans, mollusks and fish eggs, and small fish, but eat little during the winter. Spawning occurs in spring and early summer, along the coast. The eggs, averaging about one millimetre in diameter, are buoyant and drift in the upper five fathoms of water; they hatch in about six days at 54° F. (12° C.). Mackerel attain about 15 in. in length by the third year.

The genus *Pneumatophorus* comprises species strikingly similar in appearance to *Scomber* (formerly included in the latter genus) but differing in having a well-developed air bladder. These are coastal fishes of the Pacific, Indian and North and South Atlantic oceans. The North American Pacific mackerel (*P. diego*), perhaps a subspecies or even a race of *P. japonicus* of the western Pacific and Indian oceans, is abundant from the Gulf of California to central California and yields around 50,000,000 lb. a year to commercial fishermen. The chub mackerel (*P. colias*), widely distributed on both sides of the North and South Atlantic, occurs along the coast of North America, sometimes in large numbers.

The Indian mackerels (*Rastrelliger*), called striped mackerel in the Philippines and rake-gilled mackerel in Australia, are deeper and stouter than either *Scomber* or *Pneumatophorus*; but like them, they have two keels on each side of the body near the base of the tail. They grow to be about 15 in. long. At least two species are recognized, *R. brachysoma* and *R. kanagurta*. The latter occurs all around the Indian ocean and is widely distributed in the Pacific as far north as the Ryukyu Islands and Hawaii. About 18% of the total catch of sea fish in India consists of *Rastrelliger*.

The Spanish mackerels (*Scomberomorus*) are elongate, slender fishes with strong knifelike teeth. They are fishes of warm seas, but move into temperate regions as seasonal migrants or occasional visitors. The common Spanish mackerel (*S. maculatus*), the king mackerel (*S. regalis*) and the cavalla (*S. cavalla*) are taken in the western Atlantic as far north as Cape Cod and as far south as Brazil. The largest specimens of cavalla exceed 5 ft. in length, and 70 lb. in weight. The sierra mackerel (*S. sierra*) of the Pacific, which may be identical to *S. maculatus*, ranges from Peru to southern California. The largest species, *S. commersoni* of the Indo-Pacific region, is said to attain a weight of over 100 lb. Spanish mackerel are favourite game fish wherever they occur, and their flesh is of excellent quality. U.S. commercial fishermen take about 8,000,000 lb. annually, mostly along the coasts of the South Atlantic and the Gulf of Mexico.

The frigate mackerel (*Auxis thazard*), distinguished from the common mackerel in having a median keel on the caudal peduncle as well as a smaller one below and above it, has been reported from warm and temperate waters of all seas. It travels in schools, is carnivorous and grows to be about two feet long. It has little commercial value.

Horse mackerels (*Trachurus*), of the jack family (Carangidae), are shaped like common mackerels but lack finlets and have bony plates along the entire length of the lateral line. They occur in nearly all warm and temperate seas. (Large bluefin tuna [q.v.] and Atlantic bonito [q.v.], both scombrids, are sometimes called horse mackerel.) Snake mackerel is a name applied generally to a family (Gempylidae) of fishes allied to the true mackerels and especially to *Gempylus serpens*, widely distributed in deep seas. See also references under "Mackerel" in the Index.

(L. A. Wd.)

McKIM, CHARLES FOLLEN (1847-1909), U.S. architect, who was of primary importance in the American neoclassical revival, was born in Chester county, Pa., on Aug. 24, 1847. The son of a relentless abolitionist, he was educated at Harvard and at the École des Beaux Arts and trained as a draftsman by H. H. Richardson while the latter was completing Trinity church, Boston. In 1879 he joined William Rutherford Mead and Stanford

White to found McKim, Mead & White, perhaps the most successful and influential architectural firm in U.S. history. Until 1887 the firm excelled at informal summerhouses built of shingles, and McKim designed one of the most significant of these, the residence at Bristol, R.I., of W. G. Low (1887). In later years the firm was famous for championing the formal tradition of the Italian Renaissance and its classical antecedents. Among the celebrated examples of the formal planning of McKim are the Boston Public library (1887) and in New York the University club (1899), the Morgan library (1906) and the Pennsylvania station (1906-10). With D. H. Burnham and Richard Morris Hunt he charted the architectural program of the World's Columbian exposition at Chicago in 1893, which was classically inspired. He also aided Burnham in reviving Pierre L'Enfant's plan for Washington, D.C., and was the originator of the American Academy in Rome. He died at St. James, Long Island, N.Y., on Sept. 14, 1909.

See Charles Moore, *Life and Times of Charles Follen McKim* (1920); Wayne Andrews, *Architecture, Ambition & Americans* (1955).

(W. As.)

MACKINAC, STRAITS OF, the connection between Lakes Michigan and Huron. In their narrowest portion the straits are about 4 mi. wide but the straits area generally is considered as embracing a 30 mi.-long stretch of water which includes the passages between several islands in northwestern Lake Huron, Mackinac Island, within the straits, and an indefinitely defined portion of northeastern Lake Michigan. The straits, which provide a broad passage between the lakes, separate the lower and upper peninsulas of the state of Michigan. This natural barrier to land travel, which was traversed by state-operated ferryboats for many years, has been spanned by a bridge and two 20-in. submarine pipelines, carrying petroleum products from oil fields in the province of Alberta, across the straits from Pointe la Barbe on the north shore to McGulpin Point on the south shore.

Mackinac Bridge.—Extending from Mackinaw City, on the south side of the straits, to a point near St. Ignace, on the north side, the bridge with its approaches has an uninterrupted over-water length of .5 mi. and 44 ft. The main span is a suspension bridge with a total length of 8,344 ft. between cable anchorages. The centre span of the bridge, between towers, is 3,800 ft. long. The main towers are founded on bedrock more than 200 ft. below water level and extend 552 ft. above the water. The clearance under the centre span is 148 ft. above low-water datum (578.5 ft.). With David B. Steinman as designer and supervisor of construction, work began in July 1954, and the bridge was opened to traffic on Nov. 1, 1957.

See MICHIGAN, LAKE; HURON, LAKE.

(J. L. HH.)

MACKINAC ISLAND, a summer resort in Mackinac county, Mich., U.S., is located in the Straits of Mackinac, where the upper and lower peninsulas of Michigan nearly join. The island is 9 mi. in circumference and is covered with a thick growth of pine, cedar, birch and beech. After 1895 more than 80% of the area was operated as a state park by the Mackinac Island state park commission. It has a horse-and-buggy setting and automobiles are banned. The winter population ([1960] 942) is concentrated in the city on the south side.

The island was used by ancient Indians as a burial ground, and its name is a shortened form of the Indian Michilimackinac. Father Claude Dablon, a French Jesuit, wintered there in 1670 among the Huron Indians. During the American Revolution the British moved their fort from Mackinaw City to the island. Fort Mackinac was ceded to the Americans by the treaty of Paris in 1783, and during the War of 1812 a British landing party under Capt. Charles Roberts caught the U.S. garrison by surprise and forced its surrender. After the war the island was the centre of John Jacob Astor's fur-trading empire. The fur trade declined in the 1830s and Mackinac, rich in historic lore and scenic attractions such as Arch rock, Skull cave, Devil's Kitchen and Sugar Loaf, was subsequently promoted as a resort centre.

Points of interest include the Dr. William Beaumont memorial, which honours the U.S. army physician. Buildings include the Grand hotel, built in 1887, and the Moral Rearmament association's world headquarters buildings.

(E. T. P.)

MACKINDER, SIR HALFORD JOHN (1861-1947), ranked for many years as Great Britain's outstanding geographer, but it was not until the events of World War II showed the wisdom of the forecasts he made from 1904 to 1919 that his name became widely known among students of political geography. He was born on Feb. 15, 1861, at Gainsborough, Lincolnshire. In Germany, Gen. Karl Haushofer twisted Mackinder's teachings for his own purposes in promoting his doctrine of *Geopolitik*. Mackinder's famous paper, "The Geographical Pivot of History," which he read before the Royal Geographical society in London in 1904, evaluated the age-old cleavages between the heartland and coastland, the regions accessible to horsemen and shipmen respectively, and the conflicts between their peoples, with Russia, the heartland power, at the centre of his deliberations. These thoughts were further developed after World War I in his book *Democratic Ideals and Reality* (1919). (See also GEOPOLITICS.)

It would be mistaken to consider Mackinder's contributions solely in the light of his heartland vision. His great achievement was to raise geography from the slough into which it had fallen in England. At Oxford university and later at the London School of Economics, he promoted the teaching of regional and world geography. From 1910 to 1922 he served as a member of parliament and was chairman of the Imperial Shipping committee from 1920 to 1945. He died at his home in Parkstone, Dorset, on March 6, 1947.

(H. W. Wt.)

McKINLEY, WILLIAM (1843-1901), 25th president of the United States, was born at Niles, O., Jan. 29, 1843, the seventh of nine children of William and Nancy Allison McKinley. His father was of Scotch-Irish and English Puritan descent and both of his grandfathers had served in the American Revolution. McKinley's father was at times owner or renter of two or three small pig-iron furnaces that provided a meagre living for his large family. Young William obtained his secondary school education at an academy in Poland, O., where he excelled in public speaking and debate. He entered Allegheny college at Meadville, Pa., but illness brought him home at the end of his first term and family reverses prevented his return. He taught school for a time and then soon after the outbreak of the Civil War, enlisted as a private in the 23rd Ohio volunteer regi-

BY COURTESY OF THE LIBRARY OF CONGRESS
McKINLEY, PHOTOGRAPHED IN 1898

ment where he won the confidence of its colonel, Rutherford B. Hayes, and became his aide-de-camp. He repeatedly distinguished himself in action and was mustered out in 1865 with the brevet commission of major.

Early Career.—After studying law in an office and at the Albany (N.Y.) law school, he was admitted to the bar and began the practice of law at Canton, O., the seat of Stark county, in 1867. Two years later he was elected prosecuting attorney of the county. In 1871 he married Ida Saxton. She bore him two daughters whose early deaths induced her chronic invalidism, requiring McKinley's constant care of her. In 1874, in the face of prevailing hysteria against 33 rioting miners imprisoned in the Canton jail, McKinley volunteered to defend the men and obtained the acquittal of all but one of them. By this service he earned the lasting gratitude of labour. In 1876 he was elected to congress as a Republican from the 17th Ohio district and soon became an outstanding champion of protective tariffs, thereby reflecting the interests of his district.

At the beginning of his final term in congress in 1889 he competed for the speakership but lost to Thomas B. Reed, who then appointed McKinley chairman of the ways and means committee. In this position he sponsored the McKinley tariff of 1890 but its high duties led to a reaction: the election of an overwhelmingly

Democratic congress, and the end of McKinley's career as a congressman. McKinley had now attained a reputation as a national Republican leader, presiding over the Republican national convention or serving as chairman of the committee on resolutions that framed the party platforms. In 1890 he was retired from congress but was elected governor of Ohio in 1891, and was soon required to call out the militia to deal with strikes provoked by the severe depression of the early 1890s. Nevertheless he retained the loyal support of workingmen and persuaded the legislature to enact legislation in the interest of labour.

By the mid-1890s, Marcus A. Hanna, a wealthy Cleveland businessman and friend of McKinley, decided to promote McKinley's candidacy for the presidency in 1896. Though the two saw eye-to-eye on party policies Hanna was perplexed by McKinley's resolute refusal to make any deals or pledges to capture delegates. In 1893 McKinley suddenly discovered that, due to the failure of a friend whose notes he had endorsed, he was obligated to pay debts far greater than the value of his and his wife's property, which was turned over as payment. His solvency was saved by friends who came to his rescue and thereby preserved him for further public service. McKinley's re-election as governor of Ohio in 1893 increased his prestige as a national leader and in 1896 the Republican national convention nominated him for president on a platform that stressed protective tariffs and the maintenance of the prevailing monetary standard based on gold and opposed the free coinage of silver except by agreement with the leading commercial nations. Garret A. Hobart of New Jersey was chosen as the vice-presidential candidate.

The nomination of William Jennings Bryan as the Democratic candidate on a platform advocating the free and unlimited coinage of silver at a ratio of 16 to 1 to gold activated the depression-harassed agrarian debtors and upset Hanna's campaign plans. He then utilized thousands of campaign speakers and distributed millions of pamphlets promoting McKinley's election. McKinley was hailed as "the advance agent of prosperity" and the slogan, "Bill McKinley and the McKinley Bill," became a campaign cry. While Bryan ranged the country in a vigorous campaign, McKinley remained at home in Canton and from his front porch addressed thousands of visitors who arrived daily by railway trains. McKinley won by an electoral vote of 271 to 176 for Bryan and a popular majority of more than 600,000. (See UNITED STATES OF AMERICA: History.)

Presidency.—President McKinley selected his cabinet with care, but his politically motivated choice of Senator John Sherman for secretary of state proved unfortunate. Within the year Sherman was forced to resign due to ill-health but was succeeded by John Hay, an experienced diplomat. Following his inauguration, President McKinley called a special session of congress to revise customs duties; the result was the Dingley tariff, which provided for the highest average duties yet laid.

From the beginning of his administration President McKinley was deeply concerned over the Cuban insurrection. The American people were embittered by the Spanish policy of combating the insurgents by concentrating the population in camps where they suffered from disease and near starvation. Early in 1898 a letter written by Dupuy de Lôme, the Spanish minister to the United States, which severely criticized President McKinley, was intercepted by a Cuban insurgent in Havana and published in the *New York Journal*. On Feb. 15 the U.S. battleship "Maine," on an official visit to Havana, was mysteriously sunk by a submarine mine with the loss of 266 officers and men. The sensational press played up these incidents and incited a war spirit; "Remember the 'Maine'!" became the slogan of those who felt the Spanish had sunk the ship. President McKinley attempted to prevent war hysteria and endeavoured to persuade the Spanish government to adopt a conciliatory policy with respect to the Cuban insurrectionists. The Spanish government eventually did yield but the change came too late to restrain the mounting popular demand in the U.S. for intervention. When congress was at the point of a declaration of war without the president's recommendation, McKinley sent it a message asking for "forcible intervention" to establish peace in Cuba. On April 20 congress adopted a joint

resolution declaring for the freedom of Cuba, demanding that Spain withdraw from the island and authorizing the president to compel its withdrawal.

Commodore George Dewey, commanding the Pacific fleet of the U.S. navy stationed at Hong Kong, was ordered to attack the Spanish fleet at Manila. He did so and brought about its complete destruction on May 1. The Spanish home fleet meanwhile crossed the Atlantic to Santiago, Cuba, where it was confined by the U.S. Atlantic fleet under Adm. William T. Sampson until it tried to escape and was destroyed on July 3. American land forces under Gen. William Shafter invested but had failed to capture Santiago; the city finally surrendered on July 17 after severe naval bombardment and on Aug. 12 a peace protocol ended hostilities. (See SPANISH-AMERICAN WAR.)

President McKinley was perplexed as to whether the United States should annex the Philippines, but the Filipinos had risen in revolt against Spanish authority and it was doubted whether Spain could any longer govern the islands. Since the United States had annexed Hawaii in 1898, it had acquired an interest in the Pacific area and McKinley decided that the Philippines must not fall into the hands of another power. The peace treaty signed at Paris on Dec. 10, 1898, provided that Spain should relinquish title to Cuba, whose independence had been pledged by the United States, and should cede Puerto Rico, Guam and the Philippines to the United States. The ratification of the treaty remained doubtful until, under administration influence, the required two-thirds of the senate was mobilized (Feb. 6, 1899). Retention of the Philippines continued to be an issue for some time, but McKinley stood firm in his decision to retain the islands even in the face of some opposition within the Republican party.

With the acquisition of the Philippines the insurgents under Emilio Aguinaldo carried on guerrilla war against the United States until their leader was captured. There was bitter protest against this "imperialism" within the Republican party as well as by leaders of the Democratic party. President McKinley found an able administrator in William Howard Taft, an Ohio judge whom he appointed governor general of the islands. In the absence of a staff, the conduct of the Spanish-American War had fallen upon President McKinley himself, who became his own chief of staff. Secretary of War Russell A. Alger had proved inadequate and upon his resignation the president appointed Elihu Root, who reorganized the army and proved competent in dealing with Philippine problems.

President McKinley was the first president since the Civil War to assume leadership, though unobtrusively, in legislation. Following the acquisition of insular possessions he was faced with the question as to whether the entire constitution applied to them as it did to the United States itself. He accepted the view of congress that the possessions did not automatically lie within the free trade area of the United States, a constitutional issue later resolved by the supreme court with the decision in the Insular cases (1901) that these possessions were not "incorporated" territory until congress made them so and that consequently some provisions of the constitution might be inapplicable to them.

The Republican national convention of 1900 renominated McKinley with no opposition. The big question of the convention was the vice-presidency, for Hobart had died in Nov. 1899. Hanna, who was again in charge of McKinley's campaign, was opposed to the nomination of Gov. Theodore Roosevelt of New York for vice-president. The Republican organization of New York was determined to get rid of Roosevelt, whom it found troublesome, by retiring him to the vice-presidency of the United States. President McKinley virtually ordered Hanna not to interfere with the freedom of the convention in this matter, however, and Governor Roosevelt was nominated the Republican candidate for vice-president. The platform approved the Gold Standard act recently enacted by congress and the acquisition of insular territory, along with the assurance of its self-government. The Democratic convention of 1900 nominated William Jennings Bryan again on a platform condemning the gold standard and calling again for the free coinage of silver. This convention also declared that imperialism was the paramount issue of the campaign.

Because of President McKinley's well-known sincerity, Bryan's personal attacks on him backfired. The events of his administration had enhanced McKinley's prestige enormously, and the prosperity prevailing in 1900 further handicapped the Democratic candidate. McKinley was re-elected with an electoral vote of 292 to Bryan's 155 and his popular majority was nearly 850,000. This result so impressed McKinley that he said, "I can no longer be called the President of a party. I am President of the whole people."

In his second term McKinley was gratified by the decisions of the supreme court confirming the administration's limited application of the constitution to the insular possessions. The constitutional convention of Cuba posed a problem by refusing to recognize the protective interest of the United States in the island, but this was resolved by the president's firmness on that matter. McKinley planned that as one of the first acts of his second term he would make a tour of the country as far as the Pacific coast, and would speak on two subjects that had been overshadowed during the war: the control of trusts and the extension of commercial reciprocity. The one-time exponent of high protective tariffs and denouncer of free trade had been experiencing a change of heart under the tutelage of an eminent political economist, Jeremiah W. Jenks of Cornell university. He had come to recognize the importance of foreign trade. Since commercial reciprocity involved the treaty power, McKinley was preparing, through an appeal to the people on the issue, to pit the power of the executive against the power of the senate. The speaking tour was to culminate in a vigorous plea for reciprocity at the Buffalo exposition.

Deep concern had developed during the 1900 campaign concerning the possible assassination of President McKinley. Hanna had a haunting fear that McKinley might not live out a second term. The Intelligence bureau had learned of a group of anarchists at Paterson, N.J. It was reported that anarchists in Europe were plotting to assassinate the rulers of the world in the following order: Austria, Italy, Russia, England and the United States. King Humbert of Italy had just been assassinated by a former silk weaver of Paterson. As a consequence, when McKinley was shaking hands with the vast multitude of people who had come to the Temple of Music of the Pan-American exposition in Buffalo, N.Y., on Sept. 6, 1901, the most extraordinary precautions were taken for his safety. Somehow no one suspected that the scarf-wrapped hand of Leon Czolgosz, an anarchist, concealed a revolver with which he was to shoot the president. At first the doctors did not consider the president's condition serious, but he died on Sept. 14. The national mourning that followed was the most impressive since the death of Lincoln.

See M. K. Leech, *In the Days of McKinley* (1959); C. S. Olcott, *The Life of William McKinley*, 2 vol. (1916). (W. E. Br.)

McKINLEY, MOUNT, a peak of the Alaska range in south-central Alaska in lat. 63° 04' N. and long. 151° 01' W., is the highest mountain in North America (20,320 ft. above sea level). On the north and west it rises abruptly 17,000 ft., while the southern and much more gradual slope begins from an even lower level. The upper two-thirds is covered with permanent snow fields that feed many glaciers. The greatest glaciers are on the relatively inaccessible southern slope. Muldrow (30 mi. long) and Peters are the largest on the northern slope.

The Indian name of the peak was Denali ("The High One"). The modern name was applied in 1896 by W. A. Dickey in honour of William McKinley, who was elected president later that year. The first attempt to climb the mountain, made in 1903 by James Wickersham, was unsuccessful. Frederick A. Cook's much publicized (but fraudulent) claim that he had reached the summit inspired the conquest of the north peak in 1910 by two prospectors, William Taylor and Pete Anderson. The south peak (true summit) was finally attained June 7, 1913, after an expedition of three months duration led by Hudson Stuck and H. P. Karstens. In 1932 two climbers from a cosmic ray research expedition, Theodore Koven and Allen Carpe, lost their lives on the mountain. All successful ascents have been made from the north base, which became more accessible because of the Denali (park) highway.

The Mount McKinley National park (q.v.) was created on Feb. 26, 1917. See also ALASKA. (V. H. C.)

MACKINTOSH, CHARLES RENNIE (1868–1928), Scottish architect, designer and water-colourist, was one of the most significant personalities contributing to the rise of modern architecture. Born in Glasgow, Scot., on June 7, 1868, he was apprenticed to a local architect John Hutchison, and attended evening classes at the Glasgow School of Art. In 1889 he joined the firm of Honeyman and Keppie, becoming a partner in 1904.

In collaboration with three other students, one of whom, Margaret Macdonald, in 1900 became his wife, Mackintosh achieved an international reputation in the 1890s as a designer of unorthodox posters, craftwork and furniture. The outcome of this work could be seen in four remarkable tearooms he designed for Miss Cranston in Glasgow (1896–1904) and in his domestic interiors of the early 1900s. In contrast to contemporary fashion this work was notable for its lightness, elegance and originality.

Mackintosh's chief architectural projects were: Glasgow School of Art (1896–1909); two unrealized projects—the 1901 International exhibition, Glasgow (1898) and "Haus eines Kunstfreundes" (1901); Windyhill, Kilmacoll (1900) and Hill house, Helensburgh (1902); the Willow Tearooms, Glasgow (1904–05); and Scotland Street school (1904–06). Although all have some traditional characteristics, they reveal a mind of exceptional inventiveness and aesthetic perception.

By 1914, however, Mackintosh had virtually ceased to practise and thereafter he devoted himself to water-colour painting. He died on Dec. 10, 1928, in London.

See T. Howarth, *Charles Rennie Mackintosh and the Modern Movement* (1952); N. B. L. Pevsner, *Charles R. Mackintosh* (1950). (T. Hx.)

MACKINTOSH, SIR JAMES (1765–1832), Scottish writer, philosopher and Whig politician, was born at Aldourie on Oct. 24, 1765. He was educated at Aberdeen university and at Edinburgh, where he took his degree in medicine in 1787. He migrated to London in 1788, earning a living by writing for the *Oracle* newspaper and on becoming interested in politics he published *Vindiciae Gallicae* (1791), as a reply to Edmund Burke's *Reflections on the French Revolution*. Except for Tom Paine's *Rights of Man* it was the only effective answer that appeared. He prophesied that the conspiracy of the sovereigns of Europe to crush the liberties of the French people would recoil on their own heads.

The success of this pamphlet caused him to adopt the legal profession and he was called to the bar in 1795. A year after the death (1797) of Catherine Stuart, his first wife, he married Catherine Allen, sister-in-law of the Wedgwood brothers, through whom he introduced Samuel Taylor Coleridge to the *Morning Post*.

Mackintosh's greatest legal performances were his lectures in 1799 at Lincoln's Inn on the law of nature and of nations, and his defense in 1803 of Jean Gabriel Peltier, a French refugee charged with libel. On his appointment as recorder of Bombay in 1803, he was knighted, but ill-health compelled him to return to England in 1812. He entered parliament as Whig member for Northampton in 1813, and he sat for that county, and later for Knaresborough, till his death. He supported and continued Sir Samuel Romilly's penal reforms. From 1818 to 1824 he was professor of law and general politics in the East India Company's college at Haileybury. He would probably have been given office in George Canning's ministry (1827) could he have promised constant parliamentary attendance. Already a privy councillor (1827) he was appointed a commissioner for the affairs of India when the Whigs returned to office in 1830. He wrote for the *Cabinet Cyclopaedia* a "History of England from the Earliest Times to the Final Establishment of the Reformation." His more elaborate *History of the Revolution in England*, a work of original research, was published after his death, which took place on May 30, 1832.

See R. J. Mackintosh, *Memoirs of the Life of Sir James Mackintosh*, 2 vol., 2nd ed. (1836). (A. Al.)

MACKLIN, CHARLES (d. 1797), Irish actor and playwright, whose real name was McLaughlin; his distinguished though turbulent career spanned most of the 18th century and

made him a pillar of the English theatre. He first appeared as an actor at Bristol and in 1725 went to Lincoln's Inn Fields, London. A man of violent nature, he was a pioneer against the stilted declamation of his day. He went to Drury Lane theatre in 1733 and later was concerned in its management. In 1735 he killed a brother actor in the green room over a dispute about a wig, but although prosecuted he received no sentence. He set the seal on his stage career at Drury Lane on Feb. 14, 1741, when he played Shylock, rescuing the part from all the comic "portrayals" with which it had long been surrounded.

Macklin played many parts with distinction but was constantly involved in disputes and lawsuits. He attempted to be a restaurateur but failed and returned to the stage. Two of his plays were outstanding, *Love à-la-mode* (1760) and *The Man of the World* (1781). He died on July 11, 1797, claiming to be 107 years old; he may indeed have been a centenarian, though this is subject to dispute.

See Edward A. Parry, *Charles Macklin* (1891). (W. J. M.-P.)

MACKMURDO, ARTHUR HEYGATE (1851-1942), English architect, designer and a pioneer of the arts and crafts movement (q.v.), was born in London on Dec. 12, 1851. After studying at the Ruskin School of Art, Oxford, and traveling with John Ruskin to Italy, he set up practice in London. Known best for his plans for the Savoy hotel, he also built about 12 private houses—including 25, Cadogan square—and his wide interest in social problems was reflected in other types of building and several projects for communal living. Although some of his architecture shows Italian influence, its originality makes Mackmurdo a forerunner of the modern movement. He founded the Century Guild of artists (1882) to produce better furniture, etc., than was then available commercially, and designed textiles, wallpaper, furniture and metalwork. His style of the early 1880s includes swirling plant forms foreshadowing those of the later *art nouveau*. He also published *The Hobby Horse* from 1884, the first finely printed magazine on art. A friend of William Morris, he was founder member of the Society for the Protection of Ancient Buildings and was active in several art organizations. He died at Wickham Bishops, Essex, on March 15, 1942. (B. B. E. M. G.)

McLANE, LOUIS (1786-1857), U.S. congressman, diplomat, cabinet officer and business executive, was born in Smyrna, Del., May 28, 1786. At the age of 12 he entered the U.S. navy where he served under Commodore Stephen Decatur. He left the navy in 1801 to study law under James A. Bayard, a noted lawyer and congressman.

McLane's political career began in 1817 when he was elected to the U.S. house of representatives from Delaware. He served in the house until 1827 when he was elected to the senate. In 1829 he resigned from the senate to become U.S. minister to England. His principal achievement in this post was the negotiation of an agreement that reopened trade between the British West Indies and the United States. In 1831 Pres. Andrew Jackson recalled McLane from London and made him secretary of the treasury. His service in this position was made difficult by his fundamental disagreement with Jackson over the question of rechartering the Bank of the United States. McLane was transferred to the position of secretary of state in 1833 to give Jackson a chance to carry out his plans for destroying the bank. He served as secretary of state a little more than a year, resigning when he was overruled on a matter of policy.

When McLane left government service in 1834, he became president of the Morris Canal and Banking company in New York. Three years later he began a successful ten-year period as president of the Baltimore and Ohio Railroad company. While still holding this position, he was sent to England by Pres. James K. Polk in 1845 to negotiate a settlement of the dispute between the United States and Great Britain over the boundary of the Oregon territory. He died in Baltimore on Oct. 7, 1857.

His son, **ROBERT MILLIGAN McLANE** (1815-1898), was a lawyer in Baltimore, member of congress, governor of Maryland (1883-85) and U.S. minister to France (1885-89).

See S. F. Bemis (ed.), *The American Secretaries of State and Their Diplomacy*, vol. iv (1927-29). (G. C. O.)

MACLAREN, CHARLES (1782-1866), Scottish editor, who was cofounder of the *Scotsman* newspaper in Edinburgh, was born at Ormiston, Haddingtonshire, on Oct. 7, 1782. He was almost entirely self-educated, and became a clerk in Edinburgh. In 1817 when the *Scotsman* was established he at first acted as its editor. Offered a post as clerk in the customhouse, he resigned his editorial position, resuming it again from 1820 to 1845. He was editor of the 6th edition of the *Encyclopædia Britannica* in 1820. From 1864 he was president of the Geological society at Edinburgh, where he died on Sept. 10, 1866.

MACLAURIN, COLIN (1698-1746), Scottish mathematician, who alone of Newton's British successors, ranked equal with continental mathematicians of his day. Born at Kilmoran, Argyllshire, and educated at the University of Glasgow, at 19 he was elected professor of mathematics in Marischal college, Aberdeen. Two years later he was admitted a fellow of the Royal society and made the acquaintance of Sir Isaac Newton. In 1719 he published *Geometria organica, sive descriptio linearum curvarum universalis*, in which he developed several theorems due to Newton, introduced the method of generating conics that bears his name and showed that many curves of the third and fourth degrees can be described by the intersection of two movable angles. In 1721 he wrote a supplement to *Geometria organica*, which he amplified in the *Philosophical Transactions* for 1735. This paper is principally based on the following general theorem, which is a remarkable extension of Pascal's hexagram: "If a polygon move so that each of its sides passes through a fixed point, and if all its summits except one describe curves of the degrees m, n, p , etc., respectively, then the free summit moves on a curve of the degree $2mnp \dots$ which reduces to $mnp \dots$ when the fixed points all lie on a right line."

In 1722 Maclaurin traveled as tutor and companion to the eldest son of Lord Polwarth and after a short stay in Paris resided for a time in Lorraine, where he wrote an essay on the percussion of bodies, which was awarded the prize of the French Academy of Sciences for 1724. In 1725 he was made professor of mathematics in the University of Edinburgh on the recommendation of Newton.

In 1740 Maclaurin divided with Leonhard Euler and Daniel Bernoulli the prize offered by the French Academy of Sciences for an essay on tides. His *Treatise of Fluxions* (1742), written in reply to George Berkeley, contains his well-known essay on tides. In this he showed that figures of equilibrium for a homogeneous rotating fluid mass are the ellipsoids of revolution, later known as Maclaurin's ellipsoids. He also gave in his *Fluxions*, for the first time, the correct theory for distinguishing between maxima and minima in general and pointed out the importance of the distinction in the theory of the multiple points of curves.

In 1745, when Jacobites were marching on Edinburgh, Maclaurin took a prominent part in preparing trenches and barricades for its defense. As soon as the rebel army got possession of Edinburgh, Maclaurin fled to England until it was safe to return. He died on June 14, 1746, at Edinburgh.

After Maclaurin's death his *Account of Newton's Philosophical Discoveries* was published by Patrick Murdoch, and also his *Algebra* in 1748. As an appendix to the latter appeared his *De linearum geometricarum proprietatibus generalibus tractatus*, an elegant treatise.

See J. R. Newman, *The World of Mathematics* (1962).

McLEAN, JOHN (1785-1861), U.S. cabinet member and supreme court justice, was born in Morris county, N.J., on March 11, 1785. His father, a farmer, moved to Virginia in 1789, later to Kentucky and finally to Ohio. The boy's schooling was irregular, but he went to Cincinnati to study law in the office of Arthur St. Claire, Jr., and in 1807 was admitted to the bar. In 1812 he was elected U.S. representative from the district that included Cincinnati, and in 1814 was re-elected. In 1816 he was appointed a judge in the supreme court of Ohio, a position he resigned in 1822 to become commissioner of the general land office under Pres. James Monroe. Monroe in 1823 appointed him postmaster general and he remained in that office throughout the administration of John Quincy Adams. His conduct of this office was notable for its efficiency and economy, and for the nonpartisan

treatment of postmasters and other employees. Pres. Andrew Jackson continued McLean in office, but McLean refused to accept the president's views on patronage and resigned. Jackson thereupon appointed him an associate justice of the supreme court, a position he held from 1829 until his death in 1861. His most famous opinion was his dissent in the Dred Scott case (1857). In 1848 he was considered as a presidential candidate at the Free Soil convention in Buffalo, and in 1856 he was the chief opponent of J. C. Frémont at the first Republican convention, receiving 196 votes. In 1860 his name was presented for the presidential nomination at conventions of both the Constitutional Union and Republican parties. He died at Cincinnati on April 4, 1861.

See Francis P. Weisenburger, *The Life of John McLean: a Politician on the United States Supreme Court* (1937).

MACLEISH, ARCHIBALD (1892—), U.S. poet, public servant and university professor, was born in Glencoe, Ill., May 7, 1892. Educated at Yale and Harvard law school, he first came to notice as a poet with *Tower of Ivory* (1917). The verse he published in the 1920s, *The Happy Marriage* (1924), *The Pot of Earth* (1925), *Streets in the Moon* (1926) and *The Hamlet of A. MacLeish* (1928), shows the fashionable influence of Ezra Pound and T. S. Eliot. In *New Found Land* (1930) a simple lyric eloquence, the persistent MacLeish note, is heard.

In the 1930s MacLeish was concerned about the threats to American society, particularly the Fascist menace. *Conquistador* (1932) is the first of his "public" poems. Others were collected in *Frescoes for Mr. Rockefeller's City* (1933), *Public Speech* (1936), and *America Was Promises* (1939). He wrote two radio verse plays on social themes, *The Fall of the City* (1937) and *Air Raid* (1938).

MacLeish served as librarian of congress (1939-44) and assistant secretary of state (1944-45), and in various governmental positions until 1949. He aided in the establishment of United Nations Educational, Scientific and Cultural organization (UNESCO). During these years he wrote and spoke constantly in defense of American democracy. In 1949 he became Boylston professor at Harvard. Two later works are outstanding, *Active and Other Poems* (1948) and a verse drama, *J. B.* (1957).

MacLeish's collected works are *Collected Poems, 1917-1952* (1952); *A Time to Speak: Selected Prose* (1941); *A Time to Act: Selected Addresses* (1943). (W. T.)

McLENNAN, JOHN FERGUSON (1827-1881), Scottish ethnologist who challenged the theory that modern society and the state evolved from a primordial, patriarchal family, was born at Inverness on Oct. 14, 1827, and educated at King's college, Aberdeen, and at Cambridge university. He was admitted to the bar in 1857, and in 1871 became parliamentary draftsman for Scotland. His work (1857) on the article "Law" for the 8th edition of *Encyclopædia Britannica* led him to an interest in ancient forms of marriage. In *Primitive Marriage* (1865, reissued as *Studies in Ancient History*, 2nd series, 1896) he outlined his theory of social evolution, postulating small, promiscuous groups initially, with kinship recognized in the female line. Promiscuity was seen as leading to polyandry, the reckoning of descent in the male line and eventually to marriage within the group. The terms exogamy and endogamy were introduced by McLennan, who also was first to recognize the significance of totemism in social origins. *The Patriarchal Theory* was published posthumously in 1885. McLennan's significance lay in the stimulation of research through his challenging theories, most of which, however, were generally rejected. He died on June 16, 1881, in Kent, Eng.

See E. B. Tylor in *The Academy*, vol. 20, pp. 9-10 (1885); R. H. Lowie, *The History of Ethnological Theory* (1937).

(L. E. A. W.; X.)
MACLEOD, JOHN JAMES RICKARD (1876-1935), British physiologist, one of the discoverers of insulin (*q.v.*), and co-winner of the 1923 Nobel prize for medicine, was born on Sept. 6, 1876, near Dunkeld, Scotland, and was educated at Aberdeen grammar school, Marischal college, Aberdeen, and Leipzig university. From 1899 to 1902 he was demonstrator in physiology and then lecturer in biochemistry at the London hospital, holding also from 1901 to 1903 the Mackinnon research scholarship of the

Royal society. From 1903 to 1918 he was professor of physiology at Western Reserve university, Cleveland, Ohio, subsequently becoming professor of physiology, director of the physiological laboratory and associate dean of the faculty of medicine in the University of Toronto, Ont. He died March 16, 1935.

Macleod's most important work was on the nature of the control of the metabolism of carbohydrates in the animal body, and, together with Sir Frederick Grant Banting, with whom he shared the Nobel prize, and C. H. Best, he achieved fame as one of the discoverers of insulin. Macleod's publications include *Practical Physiology* (1903); *Recent Advances in Physiology*, edited by Leonard Hill (1905); *Diabetes, Its Physiological Pathology* (1913); *Fundamentals of Physiology* (1916); *Physiology in Modern Medicine* (9th ed., 1941); and numerous papers on insulin, etc.

MACLEOD, NORMAN (1812-1872), one of the most liberal and enlightened Presbyterian ministers of the 19th century, was born at Campbeltown, Scot., on June 3, 1812. He took his arts course in Glasgow, but divinity in Edinburgh, drawn thither by Thomas Chalmers. In 1838, after traveling on the continent, he became minister of Loudoun parish, Ayrshire, at a time when the conflict that was to issue in the Disruption was most intense (see SCOTLAND, CHURCH OF). Macleod threw in his lot with the small "middle party," which accepted Lord Aberdeen's proposed legislation as a satisfactory way out. At the Disruption of 1843 he moved to the parish of Dalkeith. In 1851 he was called to the Barony church, Glasgow, where he remained until his death (June 16, 1872). He was chaplain to Queen Victoria from 1857 and was elected moderator of the general assembly in 1869.

At Dalkeith, Macleod had been responsible from 1849 for a small religious periodical, the *Edinburgh Christian Magazine*. This led to his appointment in 1860 as editor of the new popular monthly magazine *Good Words*, which, during his lifetime, became a great success. His lively pen found constant use in entertainment, enlightenment and controversy, most notably in 1865 when he attacked the church's Sabbatarian policy. He worked to mitigate the strictness of Scottish religion and to encourage interest in churches abroad. From 1864 to 1872 he was convener of the Foreign Missions committee. What impressed his generation most was his versatility. He was equally at home in the pulpit of the Barony, in the editor's chair, in the workingmen's club he had founded, at Balmoral, at civic literary banquets and in the higher councils of the church.

See Donald Macleod, *Memoir of Norman Macleod* (1876); J. R. Fleming, *The Church in Scotland, 1843-74* (1927). (H. WA.)

MACLISE, DANIEL (1806-1870), Irish history painter was born at Cork on Jan. 25, 1806. At the age of 16 he left the employ of a local bank to enter the Cork school of art, maintaining himself by portrait sketching. In 1825 he made sketches of Sir Walter Scott, one of which was lithographed. He went to London in 1827 and entered the Royal Academy schools, where he carried off the highest honours. He exhibited subject pictures and portraits regularly at the Royal Academy and in 1835 was elected associate and in 1840, academician. MacLise's fame rests on the 72 lithographed portraits of literary and other contemporary celebrities which first appeared in *Fraser's Magazine* (1830-36) under the pseudonym Alfred Croquis (later published as the *MacLise Portrait Gallery*, 1871) and the two vast (12 by 45 ft.) frescoes for the Royal gallery in the house of lords "The Meeting of Wellington and Blucher" was unsuccessfully begun in fresco in 1859 and completed in a new German "water glass" technique in 1861. Its companion "The Death of Nelson" was executed between 1861 and 1864. MacLise's harsh colour was largely offset by his unusually retentive visual memory and gift for large-scale composition. He died April 25, 1870, in London. (D. L. FR.)

MACLURE, WILLIAM (1763-1840), U.S. geologist, was born at Ayr, Scotland, Oct. 27, 1763. He became known as the father of American geology because of his publication of a geological map of the United States in 1809 which antedated William Smith's geological map of England by six years. The map, together with a memoir entitled *Observations on the Geology of the United States Explanatory of a Geological Map*, was the result

of his voluntary and unaided labours.

Maclure was a liberal patron of science; from 1817 until his death he was president of the Philadelphia Academy of Natural Sciences, to which he gave his valuable private library and about \$20,000. He died at San Ángel, Mexico, March 23, 1840.

MacMAHON, MARIE EDMÉ PATRICE MAURICE DE, **DUC DE MAGENTA** (1808–1893), marshal of France and second president of the third republic, was born at Sully (Saône-et-Loire) on July 13, 1808, a descendant of an Irish Jacobite family. He was educated at St. Cyr and on entering the army (1827) began a long period of military service in Algeria. He distinguished himself in the storming of Constantine (1837) as a soldier of daring and skill. In the Crimean War he led the division that stormed Malakhov (1855) and brought about the fall of Sevastopol. His military career reached its height in the Italian campaign of 1859, when his victory at Magenta led to his being created a marshal of France and given the title duc de Magenta. He became governor general of Algeria in 1864 and gained administrative experience.

In the Franco-German War (*q.v.*) of 1870–71 MacMahon took command of the 1st army corps in Alsace, which was defeated at the battle of Wörth (Aug. 6); and he was wounded and taken prisoner at Sedan (Sept. 2). Freed by the peace, he was appointed by Adolphe Thiers to command the Versailles army which conducted the second siege of Paris, crushing the Commune in May 1871. By 1873 he was widely esteemed as a veteran soldier of proven courage and distinction, and, next to the veteran statesman Thiers, the only public figure in France capable of commanding general confidence and esteem. When Thiers resigned his position as head of state on May 24, 1873, it was to MacMahon that men looked as his successor, though his known conservative, clericalist and even royalist inclinations made him particularly the candidate of the anti-republican right. Elected president of the republic on the same day, MacMahon at the age of 65 began a short-lived but highly controversial political career for which he was ill-fitted and in which he rendered poor service to the causes that he favoured.

On Nov. 20, 1873, MacMahon was entrusted with executive power as president of the republic for a period of seven years—a decision which marked a step away from the provisional regime of Thiers toward the more definitive constitution of the third republic. His presidency was a crucial period for France, because during it the new constitution took shape and was brought into force. Important precedents were established affecting the relationship between executive and legislature. Tenure of the presidency of the republic by a professional soldier with little skill or taste for politics tended to make that office a figurehead, honorific rather than decisive. MacMahon brought to the role a personality of modest simplicity and quiet dignity with a strong sense of duty, qualities which might have made him a good president in quiet times. In formative and complex circumstances he understood too little and lent himself to party intrigue.

The constitutional laws were passed during Jan.–Feb. 1875. The elections to the new chamber in 1876 returned a large majority of republicans. This majority was confronted with a conservative president and senate, and in Dec. 1876 it compelled MacMahon to invite the moderate republican, Jules Simon, to form a government. Simon's ministry met with fierce attacks from the right and on May 16 (*le Seize Mai*), 1877, MacMahon sent him a letter that was tantamount to dismissal. Though undefeated in the chamber, Simon chose to resign, thus precipitating the constitutional crisis of *le Seize Mai*. When the president commissioned the conservative Albert de Broglie to form a ministry and won the senate's assent to a dissolution of the chamber, the issues of presidential or parliamentary control over the government were squarely posed.

Dissolving the chamber of deputies on June 25, 1877, MacMahon behaved strictly within his presidential rights, though he showed great political ineptitude, for he posed the basic issue of ministerial responsibility when he was unlikely to get the solution that he wanted. The electoral campaign was strenuous, the government using all its resources of official pressure and manipulation, the opposition denouncing MacMahon's behaviour as a *coup*

d'état. The outcome of a republican victory would be, as Léon Gambetta pointed out, that the president must either "give in or give up" (*se soumettre ou se démettre*). The results of the general election of Oct. 14 gave fewer seats, but still a decisive majority, to the republicans. By Dec. 13, 1877, MacMahon gave in to the extent of accepting a ministry led by Jules Dufaure and composed mostly of republicans. When, on Jan. 5, 1879, republicans also gained a majority in the senate, the president gave up as well, and on Jan. 28 he resigned, to be succeeded two days later by the republican leader Jules Grévy. Throughout the remaining 60 years of the third republic, no president again resorted to the power of dissolution.

The marshal died in Paris on Oct. 17, 1893. Out of his element in politics and lacking a grasp of the political realities in his day, the distinguished old soldier left a deeper mark on French government by his failures than by his achievements.

See D. Halévy, *La République des ducs* (1937).

(D. TAY.)

McMASTER, JOHN BACH (1852–1932), U.S. educator and historian, who was a pioneer in the use of social rather than purely political materials, was born in Brooklyn, N.Y., on June 29, 1852. After he graduated from the College of the City of New York in 1872, McMaster worked as a civil engineer and was an instructor in civil engineering at Princeton university, 1877–83. From 1883 until 1920 he was professor of American history in the University of Pennsylvania.

His earliest writings were on engineering subjects, but he is best known for his *History of the People of the United States, from the Revolution to the Civil War* (1883–1913). It was supplemented by *A History of the People of the United States During Lincoln's Administration* (1927). Among McMaster's other books are *With the Fathers* (1896); *A Brief History of the United States* (1907, rev. enl. ed., 1918 and 1924); and *The Life and Times of Stephen Girard, Mariner and Merchant* (1918). His textbooks were used in many U.S. elementary and secondary schools. He died in Darien, Conn., on May 24, 1932.

See E. F. Goldman, *John Bach McMaster* (1943).

MACMILLAN, the name of a family of English publishers. The founders of the firm were two Scotsmen, Daniel Macmillan (1813–57) and his younger brother Alexander (1818–96). Daniel was born on the Isle of Arran on Sept. 13, 1813, and Alexander was born in Irvine on Oct. 3, 1818. Daniel was for some time assistant to the bookseller Johnson at Cambridge, but entered the employ of Messrs. Seeley in London in 1837. In 1843 the brothers began business in Aldersgate street and in the same year they purchased the business of Newby in Cambridge. They began to publish educational works in 1844. In 1845 they took over the more important business of Stevenson in Cambridge. Daniel Macmillan died at Cambridge on June 27, 1857. The firm had begun to prosper and in 1858 a branch office was opened in London. Alexander Macmillan died in Jan. 1896. In little over half a century he had built up one of the most important publishing houses in the world which, in time, had its branches in the United States, Canada, Australia and India. Macmillan published the works of Tennyson, Charles Kingsley, T. H. Huxley, Lewis Carroll, Rudyard Kipling and many other great Victorian authors.

FREDERICK ORRIDGE MACMILLAN (1851–1936), the son of Daniel, became a partner in 1876 and first chairman in 1893, when the firm became a limited liability company. In 1898 the company purchased the business of R. Bentley and Son. Frederick's partners were his younger brother Maurice and his cousin George, both of whom died in 1936; they were succeeded by Maurice's sons Daniel (1886–1965), the chairman, and Maurice Harold (1894–

q.v.), whose son Maurice Victor (1921–) is a director.

In a reorganization of 1964 Maurice Harold became chairman of Macmillan and Co., the book-publishing side of the business. **BIBLIOGRAPHY.**—T. Hughes, *Memoir of Daniel Macmillan* (1882); *A Bibliographical Catalogue of Macmillan & Co's Publications From 1843 to 1889* (1891); C. L. Graves, *Life and Letters of Alexander Macmillan* (1910); C. L. Morgan, *The House of Macmillan* (1843–1943) (1943).

McMILLAN, EDWIN MATTISON (1907–), U.S. physicist, recipient of the 1951 Nobel prize in chemistry, with Glenn T. Seaborg, for work on the chemistry of the transuranium

elements, and co-discoverer of neptunium and plutonium, was born at Redondo Beach, Calif., on Sept. 18, 1907. He was educated at the California Institute of Technology (B.S., 1928; M.S., 1929) and Princeton university (Ph.D., 1932). He went to the University of California at Berkeley in 1932, and after a period as research fellow (1932-34) and associate (1934-35) he joined the faculty, advancing to a full professorship in 1946. From 1934 he was a member of the staff of the radiation laboratory, of which he became associate director in 1954 and director in 1958. During World War II he was engaged in research on radar and sonar (asdic) and helped establish the Los Alamos, N.M., atomic energy laboratory, where he assisted in developing the first atomic bomb. In the spring of 1940 he discovered, with Philip H. Abelson, the first transuranium element, neptunium (atomic no. 93), thus opening the whole transuranium field: Later in 1940 he initiated the search for, and was a co-discoverer of, the next transuranium element, plutonium (atomic no. 94), with Seaborg and others. He developed the theory of the synchrotron independently of and nearly simultaneously with the U.S.S.R. physicist Vladimir I. Veksler; this theory (*Physical Review*, Sept. 1945) made possible the construction of huge machines for the acceleration of electrons and atomic projectiles to very high energies, opening the field of high energy physics and convenient study of the various fundamental particles. (G. T. So.; X.)

MACMILLAN, (MAURICE) HAROLD (1894—), British statesman, prime minister from 1957 to 1963, was born in London on Feb. 10, 1894, the son of Maurice Crawford Macmillan and Helen Artie Belles. His mother came from Spencer, Ind.; his paternal grandfather, of Highland crofter origin, founded the famous London publishing house, of which Harold Macmillan became an active director in 1924. Educated at Eton and at Balliol college, Oxford, he served with the Grenadier guards during World War I, was wounded three times and won the Military cross. After the war he became aide-de-camp to the governor general of Canada, the 9th duke of Devonshire, whose daughter, Lady Dorothy Evelyn Cavendish, he married in 1920.

Macmillan stood unsuccessfully for parliament at Stockton-on-Tees in 1923, but was elected for the seat in 1924 and held it thereafter, except in 1929-31, until 1945. His prewar political career was one of party unorthodoxy: to limit unemployment, he advocated a greater degree of state control over the economy than most Conservatives thought desirable; and in foreign affairs he was a bitter critic of Neville Chamberlain's appeasement policy. He expressed his political ideas in *Reconstruction: a Plea for a National Policy* (1933) and *The Middle Way* (1938). When Winston Churchill formed his coalition government in 1940, Macmillan was given office for the first time—as parliamentary secretary to the ministry of supply. In 1942 he spent some time as colonial undersecretary and was then sent out to northwest Africa as minister resident at Allied headquarters there. He was secretary of state for air in the 1945 "caretaker" government, then lost his seat at the general election but was re-elected in Nov. 1945 in a by-election at Bromley, Kent. A pioneer of the United Europe movement, he attended the 1948 congress out of which grew the Council of Europe.

When the Conservatives returned to power in 1951 Macmillan became minister of housing and local government. He held the post until 1954 and was responsible for achieving the government's promised target of more than 300,000 new houses a year. He was then successively minister of defense (1954-55), foreign secretary (April-Dec. 1955) and chancellor of the exchequer (1955-57). As chancellor he introduced the premium bond savings scheme. He was appointed prime minister on Jan. 10, 1957, following the resignation of Sir Anthony Eden, and was elected leader of the Conservative party 12 days later.

Macmillan long devoted himself to foreign and overseas affairs. It was his support of Eden's Suez policy in 1956 that led the Conservatives to choose him as their leader when Eden resigned. Macmillan set himself particularly to strengthen relations between the U.S. and Britain. He had several meetings with presidents Dwight D. Eisenhower and John F. Kennedy concerned especially with nuclear strategy. He visited Nikita Khrushchev in Moscow in

1959, and he kept regular and personal contact with Konrad Adenauer and Charles de Gaulle. Macmillan was a firm supporter of European unity, and in 1961 his government began strenuous negotiations for terms on which Britain might join the European Economic Community. These negotiations broke down in Jan. 1963 in the face of objections to Great Britain's entry by President de Gaulle.

Macmillan visited most of the countries of the commonwealth and was the first British prime minister to set foot in India since its independence. Early in 1960 he was in Africa, and in a speech to the South African parliament spoke of the "wind of change" that was blowing through Africa and asserted the British government's opposition to the policy of apartheid. In domestic politics he exercised his power boldly. A year after he became prime minister he accepted the resignations of all three treasury ministers, and in July 1962 party discontent led him to replace 16 members of his government, including the chancellor of the exchequer and the minister of defense.

At the end of 1962 Macmillan had to contend with difficult problems of defense strategy arising from the refusal of the U.S. government to continue the development of the Skybolt air-to-ground missile. These problems were resolved at a meeting between Macmillan and President Kennedy in the Bahamas in Dec. 1962 when the Nassau agreement was concluded.

The year 1963 brought Macmillan other difficulties. The possible security risk which led ultimately to the resignation (June) of John Profumo, secretary of state for war, caused a charge of negligence to be made against Macmillan and this was utilized by those of his own party who sought a change of leader before a general election due at the latest in Oct. 1964. Nevertheless, he seemed to have ridden out the storm successfully when illness brought about his resignation on Oct. 18. (J. F. B.)

MACMONNIES, FREDERICK WILLIAM (1863-1937) U.S. sculptor and painter, whose long residence in France accounts for the strong French influence seen in all his work, was born in Brooklyn, N.Y., Sept. 20, 1863. In 1880 he was employed as a studio assistant by Augustus Saint-Gaudens. In 1884 he went to Paris to study sculpture with Jean Alexandre Falguière and Marius Jean Mercie. He returned to New York in 1887 and went again to Paris in 1889, where he remained until World War I. In 1891 he was awarded a medal of the second class at the salon—an honour never before conferred on an American sculptor. His fame was established in the U.S. by his Columbian fountain, at the 1893 World's Columbian exposition in Chicago. Among the best known of his works are "Nathan Hale," in City Hall park, New York city, his "Bacchante," in the Metropolitan Museum of Art, New York city, the battle monument, at Princeton, N.J., and his decoration for the soldiers' and sailors' memorial arch at Grand Army plaza, Brooklyn, N.Y. He was also well known as a portrait painter. He died on March 27, 1937.

See L. Taft, *History of American Sculpture* (1924). (A. T. G.)
MACNAGHTEN, EDWARD MACNAGHTEN, 1st BARON (1830-1913), was the first law lord appointed to the British house of lords directly from the bar without previous judicial experience. Born in Bloomsbury on Feb. 3, 1830, he was educated at Dublin and Cambridge universities. He was called to the bar at Lincoln's Inn in 1857. Appointed a lord of appeal in ordinary in 1887 on the retirement of Lord Blackburn after only seven years practice as a queen's counsel, Baron Macnaghten was a distinguished practitioner in chancery; but his chief distinction as a judge was his literary gift of short summaries of the factual case before him and of simple restatement and classification of the legal rules applied. Macnaghten's rule, or the right and wrong test for insanity as a defense in a criminal trial (see *INSANITY*), is not to be associated with his name but with that of a 19th-century criminal in whose case the rule was formulated. The best-known legal rule to which Baron Macnaghten's name is attached is his classification of charitable gifts into four divisions: "trusts for the relief of poverty; trusts for the advancement of education; trusts for the advancement of religion, and trusts for other purposes beneficial to the community." He died in London on Feb. 17, 1913. (A. D.M.)

McNAIR, LESLEY JAMES (1883–1944), U.S. army officer who directed the training of ground combat troops during the mobilization for World War II, was born in Verndale, Minn., on May 25, 1883, and graduated from the U.S. Military academy in 1904. McNair served with Gen. Frederick Funston's expedition to Veracruz in 1914 and with Gen. John J. Pershing's punitive expedition into Mexico in 1916. During World War I he was with the 1st division in France and with the army of occupation in Germany.

Appointed chief of staff, general headquarters, U.S. army, in 1940 (title changed to commanding general, army ground forces, when the war department was reorganized in 1942), McNair prepared the army for combat by a rigorous training program that included the use of films, obstacle courses, live ammunition and large-scale maneuvers. He sought to perfect the military skills of the individual soldier, promote the proficiency of field force units and develop teamwork among the combined arms. By stressing standardization of military doctrine and organization throughout the army, he provided for the interchangeability of individuals and units, thereby making possible their rapid and effective utilization in the diverse theatres of operation.

Assigned to the European theatre in the summer of 1944, McNair visited the Normandy front to observe the battle and was killed near St. Lô on July 25, when bombs dropped by Allied planes fell short and landed on U.S. positions. (Mn. Bn.)

McNARNEY, JOSEPH TAGGART (1893–), U.S. army officer, one of the foremost military administrators of World War II, was born at Emporium, Pa., on Aug. 28, 1893. After graduation from the U.S. Military academy at West Point in 1915, he followed a career in the air corps, which included service in France in World War I and school and staff experience in the 1920s and 1930s. McNarney was the chief architect of the important war department reorganization of March 1942, which established a simplified and effective structure. He was chosen immediately thereafter to be deputy chief of staff of the U.S. army, and his services in this position proved so valuable that he was not released for overseas duty until Oct. 1944, when he became commander of all U.S. forces in the Mediterranean. In Dec. 1945 he succeeded Gen. Dwight D. Eisenhower as commander of U.S. occupation forces in Germany, serving until early 1947 in that important and difficult position. McNarney retired in 1952 to enter private business. (A. G.)

McNAUGHTON, ANDREW GEORGE LATTA (1887–1966), Canadian army officer, commander of the Canadian army in Great Britain during World War II, was born on Feb. 25, 1887, at Moosomin, Sask. While at McGill university, Montreal, Que., he studied engineering and military subjects. Commissioned in the Canadian artillery in 1910, he went overseas as a major in 1914, served both in France and Belgium and was twice wounded. He ended World War I as a brigadier general. In 1920 he was appointed director of military training. Three years later he became deputy chief of the Canadian general staff and in 1929 was made chief, as a major general. He held this post until he became president of the National Research council of Canada in 1935. Keenly interested in scientific developments, particularly in aviation, he was joint inventor of the cathode ray direction finder.

When World War II broke out in 1939, McNaughton was recalled to the army and commanded the 1st Canadian division, which went overseas at the end of the year, and then in 1940, with the rank of lieutenant general, the VII Canadian corps, and from April 1942 the 1st Canadian army overseas. He returned to Canada in 1944 and on Sept. 27, the date of his retirement from the army, was promoted full general. From Nov. 1944 to Aug. 1945 he was minister of national defense, at a time when conscription was a burning issue. During 1945 he twice sought election to parliament but was not successful. From Jan. 1948 to Dec. 1949 he acted as Canadian representative on the United Nations Security council, and from 1950 to 1962 he was chairman of the Canadian section of the International Joint commission, which dealt with water and boundary problems between Canada and the United States. He died at Montebello, Que., on July 11, 1966. (E. B. Bn.)

McNEILE, HUGH (1795–1879), Irish Anglican clergyman and a leader of the evangelical party in the 19th century, was born at Ballycastle, County Antrim, on July 15, 1795, and educated at Trinity college, Dublin. He came under the influence of Edward Irving but was soon alienated by the latter's increasingly extravagant preaching. In 1834 he became incumbent of St. Jude's, Liverpool, where for 30 years he had great political as well as ecclesiastical influence. In 1835 McNeile entered on a long contest with the Liverpool corporation, which proposed to secularize its elementary schools by the introduction of the Irish national system. He led a fierce agitation against the threatened withdrawal of the Bible as the basis of denominational religious teaching; before the new system could be introduced every child was provided for in new Church of England schools established by public subscriptions. In 1840 McNeile published *Lectures on the Church of England* and in 1846 (the year after John Henry Newman's secession to Rome) *The Church and the Churches*, maintaining the evangelical doctrine of the "invisible church" in opposition to the teaching of Newman and Edward Pusey. In 1860 he was appointed a canon of Chester and in 1868 dean of Ripon. He died in Bournemouth on Jan. 28, 1879.

MacNEILL, JOHN GORDON SWIFT (1849–1926), Irish historian and an authority on parliamentary procedure, was born in Dublin on March 11, 1849, and educated at Trinity college, Dublin, and Christ Church, Oxford. He joined Isaac Butt's Home Rule association in 1870. Having been called to the Irish bar he was sponsored, under Charles Parnell's (*q.v.*) leadership, for south Donegal in 1887 and retained the seat until Sinn Fein routed the constitutional party in 1918. He was a professor of law at the King's inns, Dublin, and his close study of parliamentary procedure helped Parnell's party greatly in their systematic obstruction of debates at Westminster. In 1909 he became professor of constitutional law in the new National University of Ireland. In 1925, in retirement, he published his amusing reminiscences *What I Have Seen and Heard* (1925). His other books include *The Irish Parliament: What It Was, and What It Did* (1885) and *Studies in the Constitution of the Irish Free State* (1925). MacNeill died in Dublin on Aug. 24, 1926. (D. G.)

MACON, NATHANIEL (1758–1837), U.S. political leader, was born at Macon Manor in what is now Warren county, N.C., Dec. 17, 1758. He studied at the College of New Jersey (now Princeton university) from 1774 to 1776, when the institution was closed because of the outbreak of the American Revolution. From 1777 to 1780 he studied law at Bute (now Warren) county courthouse, N.C., and from 1781 to 1785 served in the North Carolina senate. In 1791 he was elected to the U.S. house of representatives where he remained until elected to the senate in 1815.

Macon's point of view was always local rather than national; throughout his career he was an aggressive advocate of state sovereignty and an adherent of the doctrines of the "Old Republicans." As speaker of the house, 1801–07, he functioned as one of the most important leaders of the Republican forces. At first on close terms with Thomas Jefferson, he associated himself briefly between 1806 and 1809 with John Randolph and a dozen other congressmen who were called "Quids." They strongly criticized Jefferson for failing to adhere to pure republican principles and bitterly opposed the choice of James Madison as his successor. By 1809 Macon was again in accord with the majority of his party and as chairman of the house foreign relations committee he fully supported Madison's foreign policy. As chairman of this committee he reported a set of resolutions designed to exclude foreign war vessels from U.S. ports and to suppress the illegal trade carried on by foreign merchants under the American flag. In a drastically revised form these provisions were incorporated in a bill passed on May 1, 1810, which restored commerce with all nations but promised to revive nonintercourse against either Great Britain or France if the other power would reverse its commercial restrictions. This bill was labeled "Macon's Bill No. 2" because Macon was chairman of the committee that reported on it, but he was not its author and opposed its adoption. He voted for the declaration of war against England in 1812, but, motivated by an exaggerated fear of government expenditure and an ill-founded faith in the value of

the militia, he opposed conscription and all taxes needed to wage war. After the war his states' rights and sectional views became even more marked; he opposed internal improvements (building roads and canals), the rechartering of the Bank of the United States and the postwar protective tariff. In his later years he was one of the outspoken defenders of slavery.

Rural and local minded, Macon was obsessed with the idea of the necessity of public economy to the point of parsimony. His industry, kindness, unquestioned integrity, and the absence of any selfish motives in his conduct made him universally liked. In 1824 Macon received the electoral vote of Virginia for the vice-presidency, and in 1826–28 he was president pro tempore of the senate. He died at Buck Spring, his home in North Carolina, on June 29, 1837.

See William E. Dodd, *The Life of Nathaniel Macon* (1903); E. M. Wilson, *The Congressional Career of Nathaniel Macon* (1900). (H. Am.)

MÂCON, a town of east central France, capital of the *département* of Saône-et-Loire, 68 km. (42 mi.) N. of Lyons by road. Pop. (1962) 25,012. Mâcon is situated on the right bank of the Saône at the foot of the Monts du Mâconnais. An 18th-century 12-arch bridge connects it with St. Laurent and the plain of Bresse. Mâcon has fine old wooden houses. Of the old cathedral of St. Vincent (12th century), destroyed during the Revolution, nothing remains but the Romanesque narthex (the part west of the nave), now used as a chapel, the façade and its two flanking towers. The prefecture, formerly the episcopal palace, dates from the 17th century; the *hôtel de ville* contains a library, a theatre and a picture gallery. Mâcon was the birthplace of the poet and politician Alphonse de Lamartine.

The town is the junction of the Paris-Marseilles and Paris-Turin railways and an important meeting place of roads. The district produces an excellent wine and large quantities are exported. Copper founding and printing are important industries; manufactures include mats, esparto articles, matches and ropes.

Mâcon (ancient Matisco) was an important town of the Aedui, but under the Romans it was supplanted by Autun and Lyons. It was sacked by the Germans, Burgundians, Vandals, Huns, Hungarians and even by the Carolingian kings. In the feudal period it was an important countship and was sold in 1239 to Louis IX (St. Louis) of France, but in 1435 Charles VII gave it to the duke of Burgundy and it did not revert to the French crown till Charles of Burgundy died in 1477. In the 16th century Mâcon became a stronghold of the Huguenots, but yielded to Henry IV in 1594. The bishopric, created by King Childebert, was suppressed in 1790. (Gd. L.)

MACON, a city of central Georgia, U.S., and the seat of Bibb county, is located about 75 mi. S.E. of Atlanta, on the Ocmulgee river, on the fall line. North Carolinians were the first settlers to build their homes on the east side of the river at Ft. Hawkins, a frontier trading post. The original settlement was called Newtown (1821), but after the Creek Indians ceded land west of the river, a site along its bank was platted in 1823 and named for Nathaniel Macon (q.v.). Newtown was annexed in 1829, and the city was chartered in 1832.

In the 1840s Macon became a market centre for cotton which was shipped downstream to Darien, and by the 1860s, with the coming of the railroads, its position as a trade and transportation centre had become established. During the American Civil War, Macon was a Confederate gold depository, and its factories produced munitions and supplies until Gen. Howell Cobb surrendered to the Union cavalry commander, Gen. James H. Wilson, on April 20, 1865.

Macon slowly rebuilt its economy during the Reconstruction period, and railroad shops, foundries, brickworks and textile mills were developed. The turn of the century saw civic improvements, which included the construction of a levee as a protection against river floods, and an extension of city limits. Economic stimulus was given during World War I with increased industrial employment and the influx of thousands of soldiers to Camps Harris and Wheeler. The United States naval ordnance plant and Warner Robins air matériel area (later Robins air force base) became

permanent installations after World War II. In the 1960s the inhabitants in the metropolitan area were principally engaged in processing and distributing agricultural products from the surrounding fertile farm lands, which include cotton, grain, pulpwood, peaches, peanuts and pecans.

There are also industries based on nearby mineral resources, such as kaolin, granite, clays, limestone and lime. Scores of newer industries, established in the area in the late 1940s and 1950s, include the manufacture of car accessories, candy, aircraft parts, drugs, clothing and chemicals.

The original settlers laid out exceptionally wide streets, which contain floral parkways. Macon's public parks are noted for their azaleas, camellias and glossy-leaved magnolias. The cultural atmosphere is enhanced by: Wesleyan college, a pioneer in higher education for women, established by the Methodists in 1836; Mercer university, founded by the Baptists at Penfield in 1833 and moved to Macon in 1871; and Georgia Academy for the Blind (1851). Amid the splendour of ante-bellum Greek Revival houses with their majestic white columns adding old south charm to the city, there is a modest cottage on High street, the birthplace of Sidney Lanier (q.v.), Georgia's most renowned poet. These homes plus Indian mounds and relics, notably the Lamar mounds and village site, at Ocmulgee National monument are major tourist attractions.

Pop. (1960) city, 69,764; standard metropolitan statistical area (Bibb and Houston counties), 180,403. In 1961 Macon annexed territory with a population (1960) of 53,112, giving the city a 1961 population, based on 1960 federal census figures, of 122,876. (S. B. K.)

McPHERSON, AIMEE SEMPLE (1890–1944), U.S. evangelist and founder of the International Church of the Foursquare Gospel, was born near Ingersoll, Ont., Oct. 9, 1890. Her public career began as a missionary in China with her first husband, Robert Semple, a Pentecostal evangelist. She returned to the United States with her daughter after her husband's death, and a second marriage to Harold McPherson was ended by her turning to full-time itinerant evangelism and healing. In this she became an outstanding success, settling finally in Los Angeles, Calif., where for almost 20 years she preached to large congregations. Besides organizing (1926) and administering the International Church of the Foursquare Gospel (known in England as Elim Foursquare Gospel), Mrs. McPherson built a radio station, founded and headed a Bible school, edited a magazine, wrote books and pamphlets and carried on extensive social service work. An attractive woman, she used her charms to the full. Her dynamic personality, prodigious energy and bizarre methods won for her countless friends and a number of enemies. Theologically she was fundamentalist and in her emphasis Pentecostal. The loyalty of her followers—in the face of her third marriage, which ended in a divorce, and various grave charges (unproved) against her—was constant.

Mrs. McPherson died on Sept. 27, 1944, from an overdose of sleeping powders. Her son Rolf McPherson succeeded her, and the movement continued to grow, reporting in the late 1960s a membership of nearly 90,000.

Mrs. McPherson's published works include *This Is That* (1923); *In the Service of the King* (1927); and *Give Me My Own God* (1936). *The Story of My Life* was edited and published in her memory in 1951. (C. S. B.)

MACPHERSON, SIR DAVID LEWIS (1818–1896), Canadian railway builder and politician, was born at Castle Leathers, near Inverness, Scot., on Sept. 12, 1818, and emigrated to Canada in 1835. After a successful business career in Montreal he moved to Toronto and in 1853 obtained the contract to build a railway line from Toronto to Sarnia, Upper Canada (later Ontario), afterward part of the Grand Trunk railway. In 1872 he headed the Inter-oceanic Railway company which sought dominion government assistance to build to the Pacific. He refused to join Sir Hugh Allan's Montreal-centred company which gained the contract but subsequently proved unable to undertake the enterprise. He published several pamphlets on economic subjects.

Macpherson was elected to the Canadian parliament as member of the legislative council for Saugeen, Upper Canada, in 1864, and was named to the dominion senate in 1867. He became speaker of the senate and minister without portfolio in the Conservative cabinet in 1880. After Oct. 1883 he was minister of the interior but retired in Aug. 1885, following the second Riel, or Northwest, Rebellion. He was knighted in 1884 and died at sea on Aug. 16, 1896. (M. Z.)

MACPHERSON, JAMES (1736–1796), Scottish poet who published between 1760 and 1763 two epics and a number of shorter poems which he claimed were translations from 3rd-century A.D. Gaelic poems composed by Ossian. This was the starting point of the Ossianic controversy, which raged for 50 years, had repercussions in French, German and Italian literature, and still attracts interest.

Macpherson was born at Ruthven, Inverness-shire on Oct. 27, 1736. He enrolled as a student at King's college, Aberdeen, in 1752, and moved to Marischal college, Aberdeen, in 1754. In 1755 he went to Edinburgh, to study for the ministry, but shortly afterward he returned as schoolmaster to Ruthven. His first verse publication, *The Highlander* (1758), was undistinguished. Jerome Stone of Dunkeld, a linguist and poet, had published a loose translation of a Gaelic ballad in the *Scots Magazine* in 1756, and this may have turned Macpherson's thoughts to the Gaelic ballads. He was encouraged also by John Home, author of *Douglas* (1757). Hugh Blair of Edinburgh collected money to finance an expedition to the Highlands, and Macpherson visited Skye, Uist and Benbecula, and later the southern Highlands and Mull, collecting Gaelic manuscripts and having Gaelic poems written down from recitation. On the first of these expeditions he probably acquired the 16th-century manuscript now known as the *Book of the Dean of Lismore*. He also acquired manuscripts written by the MacMhuirichs, hereditary bards to the MacDonalds of Clanranald. In making this collection of manuscripts and of oral literature, and in stimulating the interest of other collectors, Macpherson made an important contribution to Gaelic studies.

His first publication of supposed translations was the *Fragments of Ancient Poetry Collected in the Highlands of Scotland and Translated From the Gaelic or Erse Language* (1760). Few of these fragments have more than a tenuous connection with Gaelic originals. His next publication, *Fingal, an Ancient Epic Poem* (1762), was much more indebted to genuine Gaelic sources. *Temora* (1763) is based in part on a Gaelic ballad, but the handling of his material is much freer. He published no new translations from Gaelic after 1763.

The Ossianic controversy began shortly after the publication of the *Fragments* in 1760. The authenticity of Macpherson's work was strongly upheld by Hugh Blair; David Hume tended to be skeptical; Thomas Gray's admiration for the "translations" was tinged with doubt; Dr. Johnson's assessment of the controversy combined common sense and prejudice. None of these critics had any knowledge of Gaelic.

Macpherson's claim to have translated from 3rd-century poems can be regarded as preposterous. The earliest fragments of Irish writing are dated, in their original form, to the 6th century A.D. In Irish sources, genuine Ossianic ballads can be dated to the 11th and succeeding centuries, although the basic legends are much older. What Macpherson did was to use a number of the ballads he had collected, and to add much material of his own. In *Fingal* he used at least nine ballads; in *Temora*, apparently only one. Sometimes his translations were close to the originals, but often he misunderstood these, and frequently he changed their entire mood in his wordy attempt to create a doom-laden, "romantic" atmosphere. The descriptions of gloomy, misty landscapes come from his own experience and imagination, and the language is strongly influenced by the Authorized version of the Bible.

Macpherson steadily evaded the task of publishing his originals during his lifetime, but he left £1,000 to pay for the publication of the Gaelic, which appeared in 1807. Although many people were deceived by it then and later, it is clear that this Gaelic version is a translation of Macpherson's English. The true Gaelic ballads have been published in various collections, notably in J. F.

Campbell's *Leabhar na Féinne* (1872).

After 1763 Macpherson devoted himself to other interests, especially to business, political propaganda and the writing of history. His most important historical work is the *Original Papers, Containing the Secret History of Great Britain From the Restoration to the Accession of the House of Hanover*, two volumes (1775). He held the post of London agent to the nabob of Arcot, and entered parliament in 1780. He died at his home in Inverness-shire on Feb. 17, 1796.

McPHERSON, JAMES BIRDSEYE (1828–1864), Union general of the American Civil War, was born near the modern town of Clyde in Sandusky county, O., Nov. 14, 1828. He entered West Point in 1849 and graduated four years later at the head of his class. After being commissioned in the corps of engineers he held minor army assignments, including a one-year appointment at West Point, until the outbreak of the Civil War in 1861. At the end of the year McPherson was appointed a lieutenant colonel and aide-de-camp to Gen. H. W. Halleck in Missouri, and several months later he was assigned to Gen. U. S. Grant's staff as chief engineer in the Tennessee campaign. McPherson distinguished himself both at Shiloh and Corinth, and after the latter battle was promoted to be major general of volunteers. He participated in the second advance upon Vicksburg in 1863 in command of the XVII army corps, and after the city fell he was promoted to the rank of brigadier general in the regular army upon the strong recommendation of Grant. On March 26, 1864, after serving for a period as military commander of Vicksburg, McPherson took command of the army of the Tennessee, which was to move against Atlanta under Gen. W. T. Sherman's supreme command. Shortly after reporting to Sherman's headquarters and receiving his orders, McPherson was killed by a Confederate skirmisher, July 22, 1864. Grant is reported to have said of this universally respected young general, "The country has lost one of its best soldiers, and I have lost my best friend."

See E. J. Whaley, *Forgotten Hero: General James B. McPherson* (1955). (J. R. Co.)

MACQUARIE ISLAND, in the Pacific ocean, lies about 850 mi. S.E. of Tasmania, Austr., to which it belongs, in latitude 54° 37' S. and longitude 158° 54' E. The island, about 21 by 3 mi., forms a plateau at about 800 ft. and is treeless but well vegetated. Discovered in 1810, and a sealing base until 1919, it is now a nature reserve. A remarkable avifauna includes four species of albatross and four kinds of penguin; the royal penguin is not known to breed anywhere else. In 1948 the Australian government established a permanent meteorological and research base there. (O. H. K. S.)

MACREADY, WILLIAM CHARLES (1793–1873), English actor, manager and diarist, the greatest figure of the 19th-century stage in the development of techniques of acting and production, was born in London on March 3, 1793, the son of a minor Irish actor, who shortly afterward undertook a career as manager of provincial acting companies. Macready was entered at Rugby to prepare for the bar, but his father's financial difficulties and his own highly developed sense of personal responsibility caused him to abandon his formal education and take up temporarily, he thought, the theatre, a profession to which he was to make an outstanding contribution but for which he always felt an intense dislike. On June 7, 1810, he made his debut as Romeo at Birmingham and rapidly acquired fame in other Shakespearean and romantic roles in the provincial theatres. On Sept. 16, 1816, he appeared at Covent Garden, London, as Orestes in *The Distressed Mother*, a dull and outmoded tragedy by Ambrose Philips. Theatrical rivalry forced upon him a series of romantic and melodramatic villains, which he performed with such earnestness and truth that he became firmly established, though they did nothing

to increase his affection for the stage. On Oct. 25, 1819, he was permitted to appear as Richard III in a text that he partially purged of the "improvements" of Colley Cibber, the first of his many important efforts to restore the original work of Shakespeare to the theatre. In 1820 he created the leading role in *Virginius*, the first produced play by James Sheridan Knowles, and from that time was recognized as belonging in the front rank of English actors, contested for the first place only by Edmund Kean.

Throughout his acting career at Covent Garden and at Drury Lane, Macready devoted himself wholeheartedly to his art. His method of long study and detailed rehearsal, at a time when the general practice was casual, conventional and inspirational, anticipated much of the naturalistic method of acting developed by Konstantin Stanislavski. In 1837 he undertook the management of Covent Garden, where he was able to extend his theory of acting to all the elements involved in production. He was thus the first to impose upon the theatre of realistic illusion the principle of unity: that the actors, from star to spear carrier, the designer, the costumer and all others connected with a performance be guided and controlled by the central ideas and concepts of the playwright. Macready gave impressive demonstrations of his theory in notable revivals of *As You Like It*, *Macbeth*, *King Lear*, *Henry V* and *The Tempest*, as well as Handel's *Acis and Galatea*. The historical research that went into these productions was to have a strong influence on English stagecraft; the principle of theatrical unity was adopted and developed by the German predecessors of the duke of Saxe-Meiningen and anticipated the *régisseur* of the 20th century.

In addition to reviving standard plays, Macready also made industrious efforts to improve the repertory of modern drama. He worked closely with such professional playwrights as Sheridan Knowles and Bulwer-Lytton and worked tirelessly to persuade the leading literary figures of the day to turn to playwriting. For him, Robert Browning created *Strafford* and Sir Thomas Talford, *Ion*; Charles Dickens, his intimate friend for many years, assisted him in the search for plays, supported him in his managerial efforts and endeavoured without success to write a stage-worthy comedy. After 1825 Macready moved freely in the highest literary and artistic circles of London, and the pages of his voluminous diary (twice edited, 1875, 1912) are a happy hunting ground for literary and historical scholars.

Macready made several professional tours outside England. In 1828 he joined a group of English players in Paris, where his distinctive style, a combination of domestic sensibility and emotional power, was eagerly welcomed by the new romantic school, particularly by Victor Hugo and Alfred de Musset. He visited America three times, in 1826, 1843 and 1848. He was much impressed by the political and social achievements of democracy, particularly in the field of public education, and seriously entertained thoughts of settling in New England. However, during his last visit, he was made the scapegoat of the Nativist political movement; their attacks on him as a foreigner and an aristocrat culminated in a public riot outside the Astor Place "opera house" in New York city, during which more than 20 persons were killed by the militia and from which he narrowly escaped with his life (see FORREST, EDWIN). He abandoned all thoughts of emigrating, returned to England for his farewell performances and retired from the stage in his favourite role of Macbeth on Feb. 26, 1851.

Freed of his distasteful profession, he settled in Sherborne, Dorset, where he intended to devote himself to the education of his own large family and of the farm workers and labourers of the community. In 1823 he had married Catherine Atkins, an actress, who retired to motherhood and produced nine children. The family was cursed with ill health, the mother dying in 1852 and only one son and one daughter surviving Macready. In 1860 he married Cecile Louise Spencer, by whom he had a son. His last years were spent in increasing gloom and unhappiness in Sherborne and later in Cheltenham, where he died on April 27, 1873.

Macready was an intellectual rather than an inspirational actor, at his best in such philosophical roles as Richelieu and Hamlet. He was capable of great emotional intensity, however, and in such parts as Lear or Byron's Werner, involving paternal or domestic

feelings, he was unequalled. A lesser actor than Garrick and perhaps Kean when the latter was at his best, Macready was more important than either in his influence on the acting style and production techniques that made possible the art of the modern theatre.

MACRINUS, MARCUS OPELLIUS (c. 164–218), Roman emperor A.D. 217–218, was born about 164 at Caesarea in Mauretania (Carchel in Algeria). A lawyer, first promoted by the emperor Lucius Septimius Severus' relative and praetorian prefect Plautianus, he rose rapidly through the usual career of an equestrian (knight) to become praetorian prefect under Caracalla, sharing the office, as was then normal, with a soldier. He is alleged to have instigated the army officer who murdered Caracalla in April 217 in the course of a Parthian war, and was himself proclaimed emperor by the army three days later. After an indecisive engagement, he signed an inglorious peace with the Parthians. When the legion of Phoenicia transferred its allegiance to Elagabalus (q.v.), a son of a cousin of Caracalla, Macrinus found little support. Most of his troops deserted to his rival, and he fled toward Italy, but was overtaken and killed in Bithynia in June 218. (J.N. R. M.)

MACROBIUS, AMBROSIIUS THEODOSIUS (fl. c. A.D. 400), Latin grammarian and philosopher, whose most important work is the *Saturnalia*, the last-known example of the long series of symposiums headed by the *Symposium* of Plato. He may be the Macrobius who was praetorian prefect in Spain (399), proconsul in Africa (410) and grand chamberlain (422). He was not Italian by birth. The *Saturnalia*, which is dedicated to Macrobius' son Eustachius, purports to give an account of discussions in private houses on the day before the *Saturnalia* and on three days of that festival. There is little attempt to give dramatic character to the dialogue. It is in seven books, parts of which are not extant, and contains countless quotations from earlier writers. It is also interesting for the light it throws on the educated society of the day. Its sources include Seneca, Gellius and Plutarch. The first book discusses, among other topics, the *Saturnalia*, the Roman calendar, the sun and other divinities. The second book of which part is lost, is chiefly devoted to witticisms. The third book is partly concerned with the luxury of the ancients. The miscellaneous seventh book is partly concerned with scientific matters. The subject of part of the third book and of the fourth, fifth and sixth books is Virgil, who is treated with great reverence. His rhetoric and learning, or rather omniscience, is everywhere insisted upon.

Macrobius also wrote a commentary on Cicero's "Somnium Scipionis" ("The Dream of Scipio") from the *De Republica*. This is a neoplatonic work in two books. Plato's *Timaeus* is often mentioned. Macrobius may have used Porphyry's commentary on it, and he may also have used a neoplatonic commentary on Virgil. Of a third work by Macrobius entitled *De differentiis et similitudinibus Graeci Latineque verbi* ("On the differences and similarities of the Greek and Latin verb") only fragments remain.

BIBLIOGRAPHY.—Editions by L. von Jan, 2 vol. (1848–52); F. Eyssenhardt, 2nd ed. (1893). French trans. by H. Borneque and F. Richard, with text, of the *Saturnalia* (1937); *Commentary on the Dream of Scipio*, Eng. trans. by W. H. Stahl (1952). For fragments of the *De differentiis* . . . see H. Keil, *Grammatici Latini*, vol. v, p. 555 ff. (1868). See also T. Whittaker, *Macrobius* (1923). (G. B. A. F.)

MACROZAMIA, a genus of cycads, palmlike gymnosperms native to Australia and planted elsewhere as ornamental and conservatory specimens. See GYMNOSPERMS: *Cycadales*.

MACTAN, a low-lying coral island in the Philippines protecting the port of Cebu city (q.v.) and separated from Cebu island by a mile wide channel. Area 24 sq.mi. Pop. (1960) 57,900. On April 7, 1521, Ferdinand Magellan invaded Mactan with a force of 49 Spaniards while 1,000 Cebuano allies and 11 Spanish guards watched from boats.

In the ensuing battle Magellan was killed by the Mactans under the leadership of Lapu-Lapu, the first Filipino to defeat a west-

ern conqueror. The island is a part of the province of Cebu (q.v.). Coconut growing and fishing are important in the economy. (R. E. HE.)

MACVEAGH, (ISAAC) WAYNE (1833–1917), U.S. lawyer, diplomat and political reformer, was born near Phoenixville, Pa., on April 19, 1833. He graduated from Yale in 1853. Admitted to the bar in 1856, he was district attorney of Chester county, Pa., 1859–64. He held commands in militia forces raised to meet threatened Confederate invasions of Pennsylvania (1862–63). He became a leader in the Republican party, and from 1871 was a prominent opponent of his father-in-law, Simon Cameron, the Republican political boss in Pennsylvania.

MacVeagh was minister to Turkey, 1870–71, a member of the state constitutional convention of 1872–73, and chairman of the "MacVeagh commission," sent in 1877 by Pres. Rutherford B. Hayes to Louisiana; it secured the settlement of the contest between the two existing state governments and thus made possible the withdrawal of federal troops from the state. He was also attorney general of the United States in 1881 under Pres. James Garfield, but resigned after Garfield's death.

An advocate of civil service reform and tariff reduction, he supported (1892) Grover Cleveland, the Democratic nominee for the presidency, and was later ambassador to Italy. He returned to the Republican party in 1896. In 1903 he was chief counsel of the United States before The Hague tribunal in the case of Germany, Great Britain and Italy against Venezuela. MacVeagh died at Washington, D.C., Jan. 11, 1917.

MA'DABA, a town of Jordan, in the *liwa'* (district) of 'Amman, 21 mi. S. of 'Amman in the southwest corner of a large, fertile plain devoted largely to the growing of wheat and barley. Pop. (1961) 11,224. The town is built over a large mound under which lie the remains of earlier towns, and so rises well above the level of the surrounding plain. The population is largely Christian. In the Greek Orthodox church are the remains of the famous mosaic map of Palestine and Jordan, dating from the 6th or 7th century A.D. (see *MAP: History: Medieval Europe and Orient*). Parts of other mosaic floors can be seen in various houses, and in 1960 a fine pre-Christian mosaic came to light. (G. W. L. H.)

MADÁCH, IMRE (1823–1864). Hungarian poet, author of a poetic drama which won fame in Hungary and, in translation, in other European countries for its lofty philosophical thought and its effectiveness on the stage. He was born on Jan. 21, 1823, at Alsósztrégova, and died there on Oct. 4, 1864. A nobleman by birth, he spent his life in farming and public service.

Intelligent, with keen and catholic interests, Madách indulged in poetry and wrote several dramas, all rather weak. He secured himself a place of honour in Hungarian literature by his *Az ember tragédiája* (1861; Eng. trans. *The Tragedy of Man*, 1933), a breath-taking drama in 15 acts covering the past and future of mankind, from the creation to an ice age caused by the cooling of the sun. The central figures are Adam (who in some of the scenes assumes the personality of a well-known figure, e.g. Milton's, Tancred, Kepler, Danton), Eve and Lucifer (dramatically a most rewarding role) who, in a spirit of negation and out of spite, wishes to demonstrate the failure of God's work and the futility of man's endeavour to improve. Though his demonstration—in Madách's presentation—seems to carry conviction, he is vanquished through his inability to take into account God's infinite mercy to which Adam should pin his hopes. (Ds. Sr.)

MADAGASCAR: see MALAGASY REPUBLIC.

MADAN, MARTIN (1726–1790). English preacher and writer of the Methodist revival. Educated at Westminster school and Christ Church, Oxford, he was called to the bar in 1748 but abandoned his career and the pleasures of society after hearing John Wesley preach. He was ordained in 1750 and appointed chaplain to the Lock hospital, London. A powerful itinerant preacher, he became known as "Counsellor Madan." His acutely argued *Thelyphthora . . . A Treatise on Female Ruin* (1780), advocating polygamy to check the evils of adultery, seduction and prostitution, was bitterly attacked, but he maintained that his views were strictly in accordance with Holy Scripture. He died at Epsom on May 2, 1790.

MADDALENA, an island of Italy, in the Sassari province of Sardinia, is located 4 km. (2½ mi.) from the northeast Sardinian coast. Area 21 sq.km. (8 sq.mi.). Pop. (1961) 12,360. Napoleon I bombarded it in 1793 without success, and Nelson made it his headquarters for some time. An important naval station of the Italian fleet, it was bombed by the Allies in World War II. A bridge and an embankment connect it with the island of Caprera. (G. KH.)

MADDER (DYER'S MADDER), the root of *Rubia tinctorum* and perhaps also of *R. peregrina*, both native European plants, and of *R. cordifolia*, a native of the hilly districts of India and of northeastern Asia and Java; the last supplies Indian madder, or *manjit*. *Rubia*, a genus of about 40 species of the madder family (Rubiaceae), is characterized by lance-shaped leaves in whorls and small yellowish flowers in clusters. Madder differs from the closely related yellow bedstraw (q.v.) in having flower parts in fives and the fruit somewhat fleshy.

The red colouring principle of madder, alizarin, is now made synthetically, and the once extensive use of madder as a dye has nearly disappeared. The dye properties appear to have been known from the earliest times; cloth dyed with madder has been found on the Egyptian mummies, and it was used for dyeing the cloaks of the Libyan women in the days of Herodotus. Madder also was employed medicinally, especially in the treatment of amenorrhea, by the ancients and in the middle ages. A remarkable physiological effect of alizarin is that of colouring red the bones of animals and the claws and beaks of birds that feed upon madder. This property was utilized by physiologists in ascertaining the manner in which bones develop and the functions of the various types of cells found in growing bones.

The only native British species is *R. peregrina*, found in Wales, southern and western England and eastern and southern Ireland. *R. tinctorum*, a native of western Europe, was once extensively cultivated in southern Europe, France and the Netherlands. See also ALIZARIN.

MADEIRA (FUNCHAL), a group of islands in the North Atlantic ocean, belonging to Portugal, consists of two inhabited islands named Madeira and Pôrto Santo and two groups of uninhabited rocks named the Desertas and Selvagens. Area 797 sq.km. (307 sq.mi.). Pop. (1960) 268,069. Funchal, the capital of the archipelago, is on the south coast of Madeira Island, in 32° 37' 45" N. and 16° 55' W. It is about 360 sea miles from the African

W. SUSCHITZKY—PIX FROM PUBLIX

STREET IN FUNCHAL

coast, 535 from Lisbon, 1,331 from Southampton, 240 from Tenerife and 480 from Santa Maria, the nearest of the Azores.

Madeira (pop. [1960] 279,120), the largest island of the group, has a length of 34 mi., an extreme breadth of 14 mi. and a coast line of about 90 mi. Pico Ruivo de Santana, the highest summit, stands in the centre of the island and has a height of 6,106 ft., while some of the adjacent summits are only a little lower. The depth of the ravines, the rugged peaks, often snow covered, the bold precipices of the coast and the proximity of the sea afford many scenes of picturesque beauty or striking grandeur. The greater part of the interior, above 3,000 ft., is uninhabited and uncultivated, and the towns, villages and scattered huts are usually built either at the mouths of ravines or upon the lower slopes that extend from the mountains to the coast. The ridges between the ravines usually terminate in lofty headlands, one of which, Cabo Girão, rises sheerly to 1,804 ft., and much of the seaboard is bound by precipices of dark basalt. The north coast, being more exposed to wave erosion, is more precipitous than the south, and presents everywhere a wilder aspect. On the south is left a very little of the indigenous forest which once clothed the whole island. A long, narrow and comparatively low rocky promontory forms the eastern extremity of the island, where there is a tract of calcareous sands, known as the fossil bed, containing land shells and numerous bodies resembling the roots of trees, probably produced by calciferous infiltration.

Pôrto Santo is about 26 mi. N.E. of Madeira. Pop. (1960) 3,558. Its greatest length is 7 mi. and its width 4 mi. The capital is Pôrto Santo, called locally the *vila* or town. At each end of the island are hills, of which Pico do Facho, the highest, reaches 1,663 ft. The vine, wheat and barley are grown, but little else. There is a fine sandy beach and an airport.

The Desertas lie about 11 mi. S.E. of Madeira and consist of three islands, Ilhéu Chão, Bugio and Deserta Grande, together with Sail rock off the north end of Ilhéu Chão. They present lofty precipices to the sea on all sides. Rabbits and wild goats live on the poor pasture and attract occasional hunters to Deserta Grande, the largest islet, which is 7 mi. long by 1 mi. at its maximum width and attains the height of 1,601 ft. It was formerly inhabited.

The Selvagens or Salvages are a group of three islands, 156 mi. from Madeira and between it and the Canary Islands. The largest island is about 3 mi. in circumference.

Geology.—All the islands of the group are of volcanic origin. They are the summits of lofty mountains which have their bases on an abyssal ocean floor. The greater part of what is now visible in Madeira is of subaerial formation, consisting of basaltic and trachytic lavas, beds of tuff and other *ejectamenta*, the result of a long and complicated series of eruptions from innumerable vents. It is difficult to determine when volcanic action began in this locality, but considering the great depth of the surrounding sea it is clear that a long period must have elapsed to allow a mountain to reach the surface and then rise several thousand feet, as well as the excavation of the deep, wide ravines that everywhere dissect the island. There are now no live craters or smoking crevices.

Madeira has a few crateriform cavities. Among them are the Lagoa, a small, perfect crater 500 ft. across and 150 ft. deep on a tract 2,000 ft. high east of Funchal, and another, of a double shape, in Fanal district at nearly 5,000 ft. in northwest Madeira. In the cliff face at Ponta da Atalaia is displayed a remarkable cross section of a volcanic cone complete with lava plug. The basalt, of which much of the outer part of the island is composed, is of a dark colour and tough texture, with small disseminated crystals of olivine and augite, and often forms a rude columnar structure. The basalt yields good building stone, some of which is quarried.

Climate.—Near the coast at Funchal the mean annual temperature is about 18° C. (65° F.), February, the coolest month, having a mean of 15° (59°) and August, the warmest month, 22° (72°). As the diurnal range is small, the mildness of the climate may be judged from the mean daily minimum temperatures of 11° (52°) for February and 18° (65°) for August. At Funchal temperatures rarely fall below 7° (45°) and snow and frost are unknown. The highlands above 2,000 ft. are less clement, and mean

monthly temperatures of about 14° (58°) in August and 5° (41°) in February are more representative for summit areas. From June to September the northeasterly trades blow strongly and bring fine, dry weather. The air flow on the sheltered south coast, as at Funchal, is exceptional; there afternoon sea breezes cause southerly winds to prevail. Very rarely, a hot, dry southeasterly wind (*leste*) from the direction of Africa raises temperatures above 32° (90°). From October to late May the climate is associated with the passage eastward of cyclonic depressions which, as in the Mediterranean, give variable weather with frequent sunny spells. Yet the mean relative humidity remains low (under 65%) and cloud cover is seldom excessive. The mean annual rainfall ranges from less than 25 in. (on 55 rain days) near the south coast to 80 in. on the rainiest slopes of the exposed northern flanks and about 60 in., including occasional winter snows, on the mountaintops. Everywhere summer is dry but the runoff is ample to supply an elaborate irrigation system and power for a hydroelectric station. Madeira deservedly has a high reputation as a health and winter resort.

Vegetation.—The vegetation has a distinctly south European character. Many of the plants in the lower region undoubtedly were introduced and naturalized after the Portuguese colonization. Others are found in the Canaries and the Azores, or in one of these groups, but nowhere else. There are also about 100 plants which are peculiarly Madeiran, either as distinct species or as strongly marked varieties. Among the large number of ferns three are endemic species and six others belong to the flora of the north Atlantic islands. A connection between the flora of Madeira and that of the West Indies and tropical America has been inferred from the presence of six ferns found nowhere in Europe or North Africa but existing on the islands off the east coast of America or on the Isthmus of Panama. A further relationship to that continent can be traced by the presence in Madeira of the beautiful ericaceous tree *Clethra arborea*, belonging to a genus which is otherwise wholly American, and of a *Persea*, a tree laurel, also an American genus. The dragon tree (*Dracaena draco*) is almost extinct. Among the trees most worthy of note are some of the laurel order belonging to separate genera, an *Ardisia*, *Pittosporum*, *Sideroxylon*, *Notelaea*, *Rhamnus* and *Myrica*—a strange mixture of genera to be found on a small Atlantic island. Two heaths of arborescent growth and a whortleberry cover large tracts on the mountains. In some parts there is a belt of the Spanish chestnut at about 1,500 ft. There is no indigenous pine tree as in the Canaries, but large tracts on the hills have been planted with *Pinus pinaster*, from which the fuel of the inhabitants is mainly derived. Several of the native trees and shrubs now grow only in situations which are nearly inaccessible but some plants of foreign origin have spread in a remarkable manner. Among these is the common cactus or prickly pear (*Opuntia tuna*), which in many spots near the coast is sufficiently abundant to give a character to the landscape. The coast being rocky and the sea unique the species of algae are few and poor.

Animal Life.—No species of land mammal is indigenous to the Madeiras. The rabbit, rat, mouse and various domestic animals have been introduced. The first comers encountered seals and this amphibious mammal (*Monachus albiventer*) still lingers at the Desertas. Among the 40 species of birds which breed in the islands only one, a wren (*Regulus madeirensis*), is endemic, but five other species are known elsewhere only in the Canaries. These are the green canary (*Fringilla butyracea*, the parent of the domesticated yellow variety), a chaffinch (*Fringilla tintillus*) and a swift (*Cypselus unicolor*), a wood pigeon (*Columba trocaz*) and a petrel (*Thalassidroma bulwerii*). There is also a local variety of the blackcap, distinguished by the extension in the male of the cap to the shoulder.

The only land reptile is a small lizard (*Lacerta dugesii*), which is destructive to the grape crop. The loggerhead turtle (*Caretta caretta*) is frequently captured and cooked.

Many kinds of fish, such as the mackerel, horse mackerel, grouper, mullet and braise are caught in abundance and afford a cheap article of diet. Several species of tunny are taken plentifully in spring and summer, one of them sometimes attaining the

weight of 300 lb. There is a small whaling industry with a factory at Caniçal. The only fresh-water fish is the common eel.

A large majority of the land shells are considered to be distinctive. Many of the species are variable in form or colour, and some have an extraordinary number of varieties. About 43 species are found both living and fossilized in superficial deposits of calcareous sand in Madeira and Pôrto Santo. These deposits have been tentatively assigned to the Pliocene period. Some species have not been discovered alive elsewhere.

By the persevering researches of T. V. Wollaston the astonishing number of 695 species of beetles at the Madeiras was brought to light as early as 1870. The proportion of endemic kinds is large, and it is remarkable that 200 are either wingless or have wings so poorly developed that they cannot fly, while of 23 of the endemic genera all the species are in this condition. More than 100 moths have been collected, the majority being of a European stamp, but probably a fourth are peculiar to the Madeiran group. Among Neuroptera a certain number are distinctive.

History.—It has been conjectured, but on insufficient evidence, that the Phoenicians discovered Madeira. It is more probable that the whole archipelago was explored before the mid-14th century by Genoese adventurers, for an Italian map dated 1351 (the Laurentian portolano) depicts the Madeiras quite clearly. There is a romantic story to the effect that two lovers, Robert Machin or à Machin and Anna d'Arfet, fleeing from England to Brittany, were driven off course by a gale and landed on Madeira at the place subsequently named Machico in memory of Machin. João Gonçalves Zarco sighted Pôrto Santo probably in 1418, having been driven there by storm when exploring the coast of west Africa. When Zarco visited Madeira in 1420 the islands were uninhabited, but Prince Henry the Navigator at once began their colonization. The dense forests were subjected to felling and burning (the fires are said to have raged for seven years) and much land was brought into cultivation. The Madeiran sugar trade soon became important. Both the sugar and wine industry suffered temporary setbacks when slavery was abolished by order of the *marqués de Pombal* in 1775. From about 1660 to 1835 British influence was particularly strong; for a few months in 1801 and from 1807 to 1814 the island was occupied by British troops. It shared in the civil disturbances at the accession of Dom Miguel, but after 1833, apart from a brief abortive rebellion in 1931, it was peaceful.

Population and Administration.—Madeira has 57,611 families and a population density of 921 per square mile. The inhabitants are of Portuguese descent, with probably some intermixture of Moorish and Negro. The traditional national dress is restricted largely to flower and curio sellers in Funchal, but throughout the countryside men still favour a thick woolen cap with ear flaps and gay half boots; the people as a whole like black clothes. They are fond of fireworks at *festas*; indeed, the Madeirans are probably unexcelled in peaceful pyrotechnics and their chief display on New Year's Eve is widely attended.

Funchal (*q.v.*; pop. [1960] 43,301) is the headquarters of Madeira's commerce and industry. Over one-third of the island's total population lives within a few miles of its centre. The other chief towns, each the capital of a *concelho* (commune), are Câmara de Lobos (14,184; *concelho* 29,759) and Machico (11,608; *concelho* 21,606). Madeira's chief regular shipping connections are with Britain, Portugal, the Republic of South Africa, the United States and Brazil. There are local coastal steamship services, a much-improved road system inland and a small airport.

The archipelago is officially styled the district of Funchal. It returns two deputies to the Portuguese national assembly and is regarded as an integral part of the republic. The district is subdivided into 11 communes and 52 parishes. Funchal is a Roman Catholic bishopric in the archiepiscopal province of Lisbon.

Agriculture.—A large portion of the land was formerly entailed in the families of the landlords (*morgados*), but entails were abolished by the legislature, and the land is now absolutely free. An incredible amount of labour has been expended upon the soil, partly in the erection of walls intended to prevent its being washed away by the rains, and to build up tillable terraces. Water-

courses (*levadas*) have been constructed at regular intervals for irrigation, without which the island would not produce a hundredth part of its present yield. These watercourses originate high up in the ravines, are built of masonry or driven through the rock, and wind about for miles until they reach the cultivated land. Some of them are brought by tunnels from the rainier north side of the island through the central ridge. Each cultivator takes his allotted turn at the running stream for so many hours, day or night.

The system of cultivation is rather primitive. Few occupiers own the land they cultivate, but they almost invariably own the walls, cottages and trees, the land and irrigation water alone belonging to the landlord. The tenant practically enjoys fixity of tenure, for the landlord is seldom in a position to pay the price at which the tenant's share is valued. The *métayage* system almost universally regulates the relations between landlord and tenant, the tenant paying with a certain portion of the produce, usually one-third to one-half. There are few meadows and pastures, the cattle being stall-fed when not feeding on the mountains. Draft labour is performed by oxen.

The three staple products are wine, sugar and bananas. The vine was introduced from Cyprus or Crete soon after the discovery of the island by the Portuguese, but it was not actively cultivated until the early 16th century. The wine usually termed Madeira is made from a mixture of black and white grapes, which are also made separately into wines called tinta and verdelho, after the names of the grapes. Other wines, known as bual, sercial and malmsey, are made from varieties of grapes bearing similar names. Sugar cane is said to have been brought from Sicily about 1452. It occupies about 16,000 ac. on the south side of the island below 1,000 ft.

The common potato, sweet potato and gourds of various kinds are extensively grown, as well as the *Colocasia esculenta*, the kalo or taro of the Pacific islanders, the root of which yields an insipid food. Most of the culinary vegetables of Europe are plentiful. Beside the common temperate fruits, oranges, lemons, guavas, mangoes, loquats, custard apples, figs, pineapples and bananas are produced. The last is an important export.

Industry.—Although agriculture predominates in the Madeiran economy, handicrafts, tourism and fishing are notable subsidiaries. Wickerwork is less important than embroidery which was introduced in 1850 by a Mrs. Phelps, an Englishwoman, and now employs part- or full-time over 40,000 women. In a normal year the exports of embroidery equal or exceed in value those of wine. Handicrafts and the economy generally are also stimulated by the purchases of visitors, who number nearly 25,000 annually, not including a further 156,000 persons who stop at Funchal for a day or two en route to distant destinations.

MADEIRA RIVER in Brazil, is the main affluent of the Amazon (*q.v.*), formed in the northeast corner of Bolivia by the junction of the Mamoré and the Beni (*qq.v.*). The Madeira, which flows north, is the focal point of a riverine complex made up of the Beni, the Mamoré and the Guaporé. These rivers and their tributaries connect eastern Bolivia, part of eastern Peru and western Mato Grosso with the Amazon and the Atlantic. The Beni is navigable from Reyes to the Esperanza rapids near its confluence with the Mamoré. From Riberalta, after passing the rapids, the Beni joins the Mamoré near the town of Villa Bella. From there they flow northward as the Madeira, constituting the Bolivia-Brazil frontier until uniting with the Abuná. The Mamoré and its tributaries flow across the eastern plains of Bolivia. The Guaporé, or Iténez, the largest affluent of the Mamoré, rises in Mato Grosso and flows northwest until its confluence with the Mamoré near Puerto Sucre.

The Madeira is 2,013 mi. long from the upper sources of the Mamoré, and the general width is from $\frac{1}{2}$ mi. to 1,000 yd. When the river is at half flood the current flows at about four miles per

hour. It is navigable by seagoing vessels most of the year from its mouth near Manaus to the San Antonio falls 807 mi. upstream. This is the first of 19 falls or rapids (*cachoeiras*) blocking further passage. The Madeira-Mamoré railway, extending for 227 mi. between Pôrto Velho and Guajará Mirim, provides a link with the upper sources of the Madeira. The rainy season generally begins at the end of October and ends in March. In the dry season the river's diminution is great and navigation is adversely affected, particularly on the upper reaches of the Madeira's affluents.

The exploration of the Madeira valley began in the 16th century and parts of the region are still unexplored. Notable Portuguese expeditions which ascended the Madeira into Bolivia were those of Francisco de Melo Palheta (1723), and José Gonçalves da Fonseca (1749), who reached Mato Grosso in western Brazil. In the 19th century the Madeira region was explored by José Augustin Palacios (1884), Lardner Gibbon (1853), a U.S. naval officer, Gen. Quintín Quevedo (1861) and José and Francisco Keller (1867-68). Río da Dúvida (River of Doubt), a tributary of the Madeira, was named Río Roosevelt following its exploration by the Roosevelt-Rondon expedition in 1914.

The heavily forested, rainy tropical region through which the Madeira flows is almost uninhabited except for occasional settlements of Indians and mestizos who dwell along the banks and gather forest products such as Brazil nuts and rubber.

MADERNO (MADERNA), CARLO (1556-1629), leading Roman architect of the early 17th century, was born at Capolago, near Lugano. From 1603 until his death in 1629 he was chief architect of St. Peter's in Rome.

Maderno built the nave and façade of the church (1607-17). Consonant with the spirit of the Counter-Reformation, Maderno reverted to the scheme of early Christian and medieval cathedrals; by adding the nave he transformed Michelangelo's Greek-cross plan into a longitudinal one. His façade has been both criticized for impairing the effect of Michelangelo's dome and admired for its forceful grouping of huge engaged columns. Besides the façade of Sta. Susanna (1596 ff.) Maderno designed the Palazzo Barberini for the family of Pope Urban VIII (1625). His buildings determined the style of early baroque architecture. The Palazzo Barberini was completed by Francesco Borromini and Giovanni Lorenzo Bernini, whose works were influenced by Maderno.

See Nina Cafilisch, *Carlo Maderno* (1934).

(W. Lz.)

MADERO, FRANCISCO INDALECIO (1873-1913), Mexican revolutionary leader and president from 1911 to 1913, was born in Parras, Coahuila, on Oct. 30, 1873, the scion of a wealthy landowning family. His education, received in Paris and California, was intended to train him for a career in business and agricultural management. He became a believer in the efficacy of democracy and a devotee of spiritism with its emphasis on human progress.

After five years in Europe, he returned to Mexico in 1893 and for a time devoted himself to agricultural activities; he merits recognition as a leading pioneer in the development of the Laguna cotton region. As a landowner, Madero was known for his disinterested promotion of the well-being of his tenants. Influenced by his democratic ideology, Madero chose politics as his means of serving his countrymen. Prior to the 1905 gubernatorial election in Coahuila he helped organize the Benito Juárez Democratic club and served his apprenticeship as a political writer on its weekly, *El Demócrata*. Undiscouraged by this unsuccessful effort, Madero learned that efforts against the dictatorship of Porfirio Díaz (*q.v.*) in individual states would inevitably fail; while awaiting an opportunity for a national democratic movement, he supported and encouraged independent journalists and carried on an extensive correspondence regarding political organization.

It was Díaz himself who inadvertently brought on a renewal of political activity when he stated to the U.S. journalist James Creelman that Mexico was ready for democracy. This declaration prompted a flood of political literature and a flurry of political activity. Madero contributed to the political reawakening by the publication, early in 1909, of his book *La sucesión presidencial en 1910*, in which he emphasized the problem of militarism and viewed

the immediate political situation. Madero helped to organize the Antire-electionist party and became its presidential candidate. His correspondence, organization of political clubs and tireless and courageous campaign travels earned for him the designation of "apostle of democracy." On the eve of the farcical election, Madero was arrested on charges of fomenting a rebellion and insulting the authorities. Released on bond, he escaped across the border. From San Antonio, Tex., he issued the "Plan of San Luis Potosí," a political document which had as its principal planks effective suffrage and no re-election and which called for the revolution to begin on Nov. 20, 1910. While the initial response was sporadic, Pascual Orozco kept the rebellion alive in Chihuahua. The Díaz government, unsuccessful in the suppression of the movement by military means, undertook, successively, political reforms and negotiations with the rebels. However, the conflagration continued to spread and after the surrender of Ciudad Juárez a compromise peace was arranged.

For five months the conservative Francisco de la Barra directed an interim government whose mission was to restore order and conduct new elections. Friction occurred between revolutionaries and old regime elements and divisions appeared among the revolutionaries themselves. The presidential election resulted in a sweeping triumph for Madero, who assumed office Nov. 6, 1911. His administration was brief and difficult. He suffered from lack of political experience and was handicapped by his own overly optimistic idealism. Preoccupied with giving the people democratic conditions under which the needed reforms could be effected, Madero was attacked by the entrenched advocates of the old regime who opposed any change and by revolutionary elements who were insistent on far-reaching social and economic changes. He also had to contend with a hostile press, the harassment of U.S. Ambassador Henry Lane Wilson and a series of armed rebellions. Conservative-inspired movements were led by Bernardo Reyes and Pascual Orozco in the north and by Félix Díaz in Veracruz while Emiliano Zapata (*q.v.*) led land-hungry peasants in Morelos.

In the light of these overwhelming difficulties, the accomplishments of Madero's administration were not inconsiderable. The press and labour enjoyed freedom; agrarian reform was studied and humble beginnings of change were initiated; education was promoted; and democratic principles were applied. Many believe that Madero was moving or would have moved in the direction that the revolution demanded when, in Feb. 1913, a military revolt broke out in Mexico City. His betrayal by Gen. Victoriano Huerta caused Madero's overthrow. On Feb. 22, 1913, while being transferred to prison, Madero was assassinated by the escort.

In death Madero provided a symbol for revolutionary unity in the continuing struggle against the Huerta regime. His career and martyrdom served as an inspiration and exemplar for the establishment of a democratic polity in Mexico.

MADHAVA ACHARYA (fl. c. 1380), Hindu statesman and philosopher, lived at the court of Vijayanagar, the vigorous south Indian kingdom that so long withstood Muslim influence. He had his education under three masters: Vidyatirtha was the most important of them, looked upon as an incarnation of Maheshvara and worshiped by the pupil at Sringeri under the name Vidyasankara; the other teachers were Bharatitirtha and Sri-anthanatha. His younger brother Sayana (d. 1387), also a statesman and the minister of four successive Vijayanagar kings, is best known as the commentator of the Vedas; Sayana's commentaries were influenced by Madhava, who patronized the scholars collaborating in his brother's great work. Madhava turned ascetic about 1377 and was thereafter known as Vidyaranya. According to tradition he died in Sringeri in 1386, at the age of 90. He was part author of *Jivanmuktiviveka* and *Panchadasi*, works of Vedanta philosophy; *Dhatuvritti*, a treatise of Sanskrit grammar; and *Nyayamalavistara*, on the Mimamsa system; as well as the *Parasarasmitivakyha*, an elaborate comment on the *Parasara-mriti*, adding a chapter on law to those on custom and penance.

in the original. Madhava Acharya should not be confused with his contemporary Madhavamantrin, statesman, warrior and author, or with a later Madhava, the author of *Sarvadarsana Samgraha* ("Compendium of Speculations"). (K. A. N. S.)

MADHYA (ANANDATIRTHA; PURNAPRAJNA) (c. 1199-c. 1278), a prominent Hindu philosopher, was born at Rajatapitha near Udipi in south Kanara. Little is known of his life, but 37 Sanskrit works are attributed to him, dealing chiefly with the interpretation of Hindu sacred writings and the explanation of his own theological system.

According to Madhva, Vishnu (Krishna) is the one eternal God who rules the world and grants salvation to his devotees. Both souls (*jiva*) and matter (*prakriti*) coexist eternally with Vishnu. The individual souls are spiritual beings of atomic size, blissful by nature. As they are from eternity connected with matter and subject to the law of retribution for their deeds (*karma*), they wander about in bodies of angels (*deva*), men, animals and infernal beings, subject to pain and suffering. The inanimate world originates from primordial matter, out of which all elements and the organs and bodies of the souls are produced by evolution. The aim of man must therefore be to become free from impurities, ignorance, passion, *karma* and matter. The means of salvation is the grace of Vishnu, who predestines the souls to deliverance, permanent transmigration or eternal damnation in hell.

Madhva's teaching differs in two points from that of other Vedantins who like him base their doctrines on the Upanishads, the Bhagavad Gita and the Brahma Sutras: believing in the metaphysical reality of souls and matter, he repudiates all theories which attempt to reduce them to an illusion (*maya*), and he rejects all pantheistic ideas, as God is only the efficient, not the material, cause of the universe.

Madhva's philosophy is called Dvaita ("dualism"), because it acknowledges a difference in kind between God and souls. Salvation therefore consists not in the absorption of the soul into the absolute but in the independent existence of the released in Vishnu's supernatural world.

See H. von Glasenapp, *Madhva's Philosophie* (1923); S. Dasgupta, *History of Indian Philosophy*, vol. iv (1949). (H. v. G.)

MADHYA PRADESH, the largest state in the Republic of India (area 171,217 sq.mi.), lies as its name implies (Madhya, "central"; Pradesh, "region") in the heart of the subcontinent and has no seaboard. With the independence of India in 1947 the British Indian Central provinces and Berar were together restyled Madhya Pradesh, but boundary changes soon followed. The old Central India agency (divided after independence into Madhya Bharat and Vindhya Pradesh) was added to Madhya Pradesh; at the same time the eight Marathi-speaking districts of Akola, Amravati, Bhandara, Buldana, Chanda, Nagpur, Wardha and Yeshwantpur were ceded to Bombay (later Maharashtra) state. As redefined under the States Reorganization act of Nov. 1, 1956, the present boundaries of Madhya Pradesh bear little relation to those of the old Central provinces.

The present state comprises the former Madhya Bharat (except for the Sunel enclave of Mandsaur district), Vindhya Pradesh and Bhopal, together with the 14 Hindi-speaking districts of the former state of Madhya Pradesh, and the Sironj subdivision of Kotah district of Rajasthan. (Madhya Bharat comprised the united states of Gwalior, Indore and Malwa. Vindhya Pradesh included 25 states of Baghelkhand and Bundelkhand.)

Madhya Pradesh is bordered by seven states: Rajasthan, Uttar Pradesh, Bihar, Orissa, Andhra Pradesh, Maharashtra and Gujarat. Roughly 80% of the people are Hindi-speaking. The state capital is Bhopal.

Physical Features.—The whole state lies on the great plateau of India, the northern boundary coinciding roughly with the edge of the plateau overlooking the great plains of northern India. There is very little land below 1,000 ft. above sea level and on the eastern margins considerable tracts lie above 3,000 ft. The rolling plateau country is crossed by several west-east ranges, notably the Vindhya mountains and the Satpura range between which is the trough occupied by the westward-flowing Narmada

(Narbada) river. The Narmada trough is continued northeastward by the valley of the Son, draining into the Ganges (Ganga), and the Narmada-Son line is often taken as the natural limit between northern and peninsular India. South of the Satpura range lie the open plains of Maharashtra's black cotton soil; the eastern part of Madhya Pradesh has broad valley plains in which most of the settlement and cultivation are concentrated; the plains are separated by forested hills rising on the whole eastward but drained mainly by tributaries of the Mahanadi.

Climate.—The state has a wide range of climate with an annual rainfall increasing from under 25 in. in some western plains to 60 in. and more on the forested hills of the east. The northern tracts have the considerable range of temperature found in the Delhi-Kanpur plain with a long pleasant cold season and a hot season there tempered by the elevation. Similarly the Vindhya and Satpura districts are comparatively temperate but the Narmada valley is enclosed and hot. The more humid regions in the east of the state tend to be steamy during the rains. Harvests are variable on the plateau valley-plains since the early rains are often deficient or late in arriving and the late rains may cease prematurely and cause heavy losses. Despite the adequate average rainfall suggested by the records, irrigation is much needed as an insurance against seasonal fluctuations.

Vegetation and Animal Life.—An outstanding feature of the physiographical aspect of Madhya Pradesh is the vast extent of forest and scrub. Of the great trees of the forests the sal (*Shorea robusta*) is among the most important. Mammals in the jungle include wild buffalo, gaur (bison), tiger, nilgai, red dog, panther, hyena, sambar, black buck and many other larger kinds of deer, wild pig, wildcat and innumerable monkeys. There are peacocks, jungle fowl, sand grouse, partridges and green pigeon, and many varieties of duck and other waterfowl on the big tanks. Snipe abound in the paddy fields. Crocodiles are to be found in the rivers, and there are cobra and the deadly Russell's viper and krait and many other types of snakes in the forests and plains. There is an immense variety of insects.

In 1955 the Kanha wildlife sanctuary, 180 mi. N.E. of Nagpur, was declared a national park. It covers 99 sq.mi. and is known chiefly for the Indian swamp deer (barasingha), but it also has tiger, leopard, gaur, chital, black buck, sambar and barking deer.

(L. D. S.)

History.—Probably the earliest inhabitants of large tracts of Madhya Pradesh were the ancestors of the modern Bhils, Gonds and other primitive tribes still to be found in this area. In the lifetime of the Buddha, Avanti, with its capital at Ujjain, formed one of the 16 states referred to in the Buddhist canonical book, *Anguttara-Nikaya*. To the east of Avanti, also in central India, lay the territories of the Chedis and the Vatsas. Madhya Pradesh, geographically the heart of India, formed part of the great Mauryan empire. It was Asoka who built the famous group of stupas around Bhilsa, of which that at Sanchi is the best known. After the decline of Mauryan power the Sungas apparently ruled in eastern Malwa in the 2nd century B.C. They were supplanted by the Andhras who had extended their sway over eastern Malwa. About A.D. 150 Sanchi and Vidisa (modern Beshnagar) were annexed to the territories of the Saka (Western) Satraps by their most famous ruler Rudradaman. Later the whole of Madhya Pradesh to the north of the Narmada formed part of the Gupta empire. The eastern part of Malwa was later overrun by the White Huns. In the 6th century the powerful Kalachuri (Chedi) ruler seized the Narmada valley and took possession of most of Bundelkhand and Baghelkhand. The Narmada probably formed the boundary between the dominions of Harsha (q.v.), which included large tracts of Madhya Pradesh, and the territories of his great rival Pulakesin II, the Chalukyan ruler of the Deccan. In the 9th century the Gurjara-Pratiharas of Kannauj ruled over central India, though in eastern Malwa the Narmada formed a fluctuating frontier between the Rashtrakutas of the Deccan and the Paramaras to the north.

It was not until the 13th century that the Muslim invaders penetrated this area. In 1234, Iltutmish, the ruler of Delhi, captured Bhilsa and Ujjain. In the early years of the 14th century Malwa

was again overrun, by the forces of the Khalji sultans of Delhi. Madhya Pradesh was included in Mohammed Tughluq's extensive empire. When Babur invaded India in 1526, the western districts of what is now Madhya Pradesh had been absorbed into the kingdom of Malwa and the eastern portion had been annexed by the Gond rulers of Gondwana. It was not until the reign of Akbar that Malwa was annexed to the Mogul empire. About the same time Akbar's troops forced their way into the wild regions of Gondwana and, after a gallant resistance, Durgavati, the queen mother, was killed in a battle fought near Jabalpur, but it is doubtful whether Akbar annexed the whole of Gondwana. The weakness of the Mogul empire in the first half of the 18th century gave the Marathas an opportunity to make a bid for paramountcy in India. Maratha raids into Malwa had begun toward the end of Aurangzeb's reign and from that time onward central India was never secure from their depredations. By the year 1734 they were firmly established in Malwa. This was a great strategic advantage as Malwa lay athwart the main routes connecting the Deccan with northern India. Two years later they had carried their depredations into Bundelkhand. By 1760 they had consolidated their power over the whole of Madhya Pradesh between the Chambal and the Narmada. The defeat of the Maratha peshwa's forces at Panipat in 1761 while it weakened the confederacy increased the power of the Maratha generals and enabled Sindhia to establish himself in Gwalior, and Holkar to become independent in Indore. The early 19th century was marked by the growth of anarchy when Pindari robber bands, supported by Holkar and Sindhia, ravaged central India from Malwa to Bundelkhand. By the year 1818 the suppression of the Pindaris and the final defeat of the Marathas made the British the paramount power in India. In that year the "Saugor-Nerbadda" territories were ceded to them and were administered as part of the province of Agra. Sindhia of Gwalior, Holkar of Indore and all the states of central India came under British protection. The settlement and pacification of this area were the work of Sir John Malcolm. Between 1830 and 1835 the Thugs who infested central India were suppressed by Sir William Sleeman. The remaining districts of the present Madhya Pradesh came under British rule when the Nagpur state was declared an escheat in 1853. In 1861 these districts and the "Saugor-Nerbadda" territories were incorporated into the Central provinces.

On June 14, 1857, troops of the Gwalior contingent at Morar were the first to mutiny in central India. In the same month the Indore state troops guarding the residency followed suit. Further outbreaks occurred at Nimach, Nowgong, Mhow and Nagod. The suppression of the mutiny in this quarter was the work of Sir Hugh Rose (*see* STRATHNAIRN, HUGH HENRY ROSE, 1st Baron). The leaders of the rebellion were the rani of Jhansi and the Maratha Brahman Tantia Topi. The rani was killed fighting in the attack on Gwalior and Tantia Topi was captured and finally executed in April 1859. After the suppression of the mutiny the history of Madhya Pradesh was a record of steady improvement and unbroken peace under British rule.

The term Central India was officially applied at first to Malwa alone; but in 1854 Bundelkhand and Baghelkhand were added to Malwa to form the Central India agency. In 1901, for administrative purposes, it was divided into the following eight units: the Gwalior residency; the Indore residency; the Baghelkhand agency; the Bhopal agency; the Bhopawar agency; the Bundelkhand agency; the Indore agency; and the Malwa agency. The chief administrative changes after 1901 were: the abolition of the Indore agency in 1907 and its amalgamation with the Malwa agency; the removal of Gwalior from the agency in 1921; and the amalgamation in 1931 of the Baghelkhand and Bundelkhand agencies. After 1947 the Central India agency was divided into Madhya Bharat and Vindhya Pradesh, which, together with Bhopal and the predominantly Hindi-speaking districts of the former Central provinces, were united in 1956 to form the state of Madhya Pradesh.

Population and Administration.—The population of Madhya Pradesh, mostly Hindus, at the 1961 census was 32,372,408; an increase of 24.2% since 1951, when it was 26,071,637. The

chief cities and towns, with their populations according to the 1961 census, are: Indore (394,941); Jabalpur (295,375); Gwalior (300,587); Bhopal (185,374); Ujjain (144,161); Sagar (104,676); Ratlam (87,472); Khandwa (63,505); and Bilaspur (86,706). The people are of diverse ethnic origin, the chief tribal groups being the Bhil, Munda, Baiga, Gond, Maria, Mandia and Bhattrra. One out of every seven persons belongs to one of the tribes.

While Hindi is the chief language spoken and understood throughout the state, as many as 377 languages and dialects were returned as mother tongues at the 1951 census. A considerable number of these dialects are spoken by the tribal population.

Executive power is vested in the governor (appointed by the Union president) who acts on the advice of a council of 11 ministers. The legislative assembly comprises 289 members. Madhya Pradesh is divided administratively into 43 districts, grouped in seven divisions, each under a commissioner: Sehore, Raisen, Vidisha (Bhilsa), Hoshangabad, Betul, Rajgarh, Shajapur (Bhopal division); Bilaspur, Raigarh, Surguja (Bilaspur division); Gwalior, Bhind, Morena, Shivpuri, Guna, Datia (Gwalior division); Indore, Ratlam, Ujjain, Mandasaur, Dewas, Dhar, Nimar (East and West), Jhabua (Indore division); Jabalpur, Balaghat, Chhindwara, Seoni, Sagar, Mandla, Damoh, Narsimhapur (Jabalpur division); Raipur, Bastar, Durg (Raipur division); Rewa, Sidhi, Satna, Panna, Chattarpur, Tikamgarh, Shahdol (Rewa division).

Comparatively backward in education—in 1961 17% of the population was literate—the state had nevertheless made significant progress by the mid-1960s. There are more than 29,000 primary schools and 4,000 schools for general, vocational and technical education; *i.e.*, 1 school for every 800 persons. Primary education is free and compulsory in over 100 towns and nearly 3,000 villages. About 150 colleges and 4 universities—at Sagar, Jabalpur, Ujjain (Vikram university) and a university of music at Khairagarh—provide general, professional, technical and special education. There are more than 1,000 medical institutions including hospitals, dispensaries, health centres and family planning clinics. The Employees' State Insurance plan covers sickness, maternity and employment injury risks and provides medical care through about 30 exclusive dispensaries in 8 centres to more than 70,000 factory workers and their families.

For the tribal and backward classes, constituting a third of the state's population, special education, training and welfare schemes are run by the government. The Social Welfare board conducts welfare activities for destitute women, children, beggars and orphans, and also provides primary and adult education, and crafts-training for women. (S. Ch.; S. B. L. N.)

The Economy.—The large majority of the population is dependent on agriculture, and almost every crop grown in India is to be found in Madhya Pradesh. A line drawn from Satna in the north to Balaghat in the south roughly divides the agriculture of the country. East of that line, where the rainfall is heavy, the principal crop is rice; west of it wheat, gram, maize (corn), oil-seeds, sugar cane, fruit, tobacco, cotton and jowar (sorghum) are chiefly grown. The Narmada valley and the Vindhyan districts are the great wheat-producing areas; the two Nimar districts (south of the Narmada) are the great cotton and jowar tracts. But while cotton and jowar are insignificant in the rice country, and rice is insignificant west of the Satna-Balaghat line, practically every district in the state contains some heavy black soil areas that produce wheat and cold-weather crops. This variety of soil and cropping affords a certain degree of insurance against capricious rainfall. Rice is the most important cereal; the others are wheat, jowar, maize, barley, and pulses and peas of many kinds. There are considerable sugar cane and banana plantations, and oranges and citrus fruits are grown in large quantities. The state as a whole is a surplus area, and production has been increased by long-term planning. Under the second five year plan (1956-61) the state was scheduled for a large surplus of agricultural production, aided by an extension of tank irrigation and major works on the Tawa river, but achievement fell far short of the targets. The Chambal multi-purpose project (completed 1962) was irrigating about 700,000 ac. of land and generating 210,000 kw. of hydroelectric power. The main cash crops are cotton and sunn; there

are also large areas under oilseeds, peanuts, linseed and sesame. Animal husbandry is receiving increasing attention. Vast tracts (about 30% of the total area of the state) are under forest, and the state is the largest producer of timber (including the best quality teak and sal), firewood and minor forest produce in India.

Mining and Heavy Industry.—Madhya Pradesh is rich in minerals, and the eastern region is believed to be the most highly mineralized area in the whole country. The manganese deposits, chiefly in Balaghat district and extending across the Maharashtra border into the districts of Nagpur and Bhandara, are among the best in the world. Iron ore is to be found in Durg, Jagdalpur and Sagar districts and in the former Madhya Bharat region (that in Jagdalpur is believed to be of high-grade quality), and mining was being developed in the 1960s. The chief coal mines are in Chhindwara and Ambikapur districts; development of those at Korba is taking place, and the state's annual output exceeds 5,000,000 tons. Limestone is found in large quantities in the Vindhya mountains and India's largest cement works are at Kymore, near Katni, while others are at Satna and Barmore; the total output of the three approaches 1,000,000 tons a year. There are in addition bauxite deposits, asbestos and alluvial gold in the state, which also produces 95% of India's diamonds.

The extent and variety of mineral deposits makes Madhya Pradesh an obvious centre of heavy industry, and a steel plant at Bhilai in Durg district, one of the three under India's second five-year plan, has a scheduled capacity of 1,300,000 tons a year. Limestone and manganese are to be found in the neighbourhood, and there are large iron deposits at Dalli-Rajara, 50 mi. to the south, and blending coal is available 140 mi. away at Korba. The U.S.S.R. agreed in 1955 to furnish all the equipment (to be paid for over a period of 12 years) and technical assistance needed for the construction and operation of the steel works. The heavy electrical plant at Bhopal began production in 1960. Another major industry is newsprint manufacture. The Nepa mills at Napanagar in Nimar East (Khandawa) district, the first of their kind in India, began production in 1955. Using salai wood, which is grown in large quantity in the state, they have an output of 30,000 tons a year. A paper mill, with foreign financial and technical aid, was constructed at Amlai near Shahdol.

Other industries include textiles, oil and sugar refining, cement and match manufacturing, and engineering. There are old-established potteries at Gwalior. The state is also known for its traditional village and home crafts. These include Chanderi saris and turbans (Maheshwar and Chanderi), woodwork and lacquer ware (Shyapuri and Sabalgarh), and wooden toys (Bhopal).

Madhya Pradesh is served by three railroad systems; the South Eastern leading into Orissa and West Bengal, the Central into Maharashtra, Andhra Pradesh, Uttar Pradesh and Delhi, and the Western into Rajasthan and Gujarat. (L. D. S.)

MADI (Ma'di), a Sudanic-speaking people who inhabit both banks of the Nile river in the west Nile district of northern Uganda (q.v.). They numbered about 67,000 in the 1960s, including a few thousand living in the southern Sudan. They are closely related to their Lugbara (q.v.) neighbours to the west. Primarily hoe cultivators, with millet as the staple crop, they also fish, hunt and keep cattle in areas where bovine sleeping sickness does not prevent it; smithing is an important craft. The Madi are composed of groups of diverse ethnic origins, including Lugbara, Bari (q.v.), Kakwa, and Acholi. They have three main divisions: western Madi on the Otzi massif, eastern Madi on the Nile flats, and southern (or "goat") Madi along the west bank of the Nile. The country is divided into areas under the ritual care of "owners of the land," and about 25 chiefdoms have boundaries that differ from those of the ritual lands. The chief is the head of the dominant

patrilineal clan which was first settled in the chiefdom, later immigrants being grouped into accessory lineages. The chiefship is divided among four functionaries (ideally half brothers) the most powerful being the "chief of the people," who had government recognition in the 1960s. The "chief of the rain," the "chief of the cattle," and a fourth who protects the graves and relics of departed chiefs are mainly ritual figures; only the rainmaker has any great importance. Ritual centres on worship of ancestors and a supernatural force, *Rubanga*. See also AFRICA: *Ethnography* (*Anthropology*): *East Africa*; SUDANIC LANGUAGES.

MADISON, JAMES (1751–1836), 4th president of the United States, often called "the father of the constitution," was born at Port Conway, in King George county, Va., on March 16, 1751. His great-great-grandfather, John Maddison (so spelled), a ship carpenter, came from England to take up 600 ac. in 1653. His father, also named James Madison, was the owner of large estates in Orange county, Va.

In 1769, Madison entered the College of New Jersey (now Princeton university). Graduating in 1771, he remained for another half year pursuing studies under the direction of the college president, John Witherspoon (1723–94). In 1772 he returned to Virginia, where he continued his reading and studies in religion and law. In Dec. 1774, as friction between the colonies and England increased, he was chosen a member of the Orange county committee of public safety of which his father was elected chairman. In the spring of 1776 he was chosen a delegate to the Virginia constitutional convention, where he was on the committee which drafted the declaration of rights and the Virginia constitution; he played a major role in the formulation of the article on religious freedom in the declaration of rights. As the constitution provided that the members of the convention should constitute the house of delegates, Madison became a member of the first Virginia state legislature. But in 1777, largely, it seems, because he refused to treat the electors with rum and punch as was the custom, he was not re-elected. In November he was chosen a member of the privy council or council of state, in which capacity he took a prominent part from Jan. 14, 1778, until the end of 1779, when he was elected to the continental congress.

As a member of the continental congress during the final stages of the Revolutionary War, he drafted instructions in 1780 to John Jay, then representing the United States at Madrid, that in negotiations with Spain he should insist upon the free navigation of the Mississippi and upon the principle that the United States succeeded to British rights affirmed by the treaty of Paris of 1763. When the government under the articles of confederation faced collapse because of the failure of the states to respond to requisitions of congress for supplies for the federal treasury, Madison was among the first to advocate the granting of additional powers to congress, and urged that congress should forbid the states to issue more paper money. In 1781 he favoured an amendment to the articles of confederation giving congress power to enforce its requisitions; and in 1783, in spite of the open opposition of the Virginia legislature, he advocated that the states should grant to congress for 25 years authority to levy an import duty. In the same year he was a member of the committee which reported a skilful compromise on the Virginia proposal as to the terms of cession to the confederation of the unoccupied western territory, held by several states.

When his term in congress expired, in Nov. 1783, Madison re-

MADISON, PORTRAIT BY ASHER B. DURAND, 1833

turned to Virginia to study law. In the following year he was elected to the house of delegates. As a member of its committee on religion, he opposed giving special privileges to the Episcopal (or any other) Church, and spoke against a general assessment for the support of the churches of the state. His petition of remonstrance against the proposed assessment, drawn up at the suggestion of George Nicholas (c. 1755-99), was widely circulated and procured its defeat. On Dec. 26, 1785, Thomas Jefferson's bill for establishing religious freedom in Virginia, which had been introduced by Madison, was passed. In the Virginia house of delegates, as in the continental congress, he opposed the further issuance of paper money; and he tried to induce the legislature to repeal the law confiscating British debts.

Role in Forming Federal Constitution.—Meanwhile he did not lose sight of the interests of the confederation. His proposal for a conference between Maryland and Virginia relating to the navigation and commerce of the Potomac river led to a meeting of commissioners from the two states in March 1785. When the Maryland legislature proposed to invite Pennsylvania and Delaware to join in an arrangement, Madison, seeing an opportunity for more general agreement, proposed that all the states should be invited to send commissioners to consider commercial questions. A resolution to that effect was adopted (Jan. 21, 1786) by the Virginia legislature. This led to the Annapolis convention of 1786, and that in turn led to the Philadelphia convention of 1787. (See ANNAPOLIS CONVENTION; CONSTITUTIONAL CONVENTION [U.S.])

In April 1787, Madison wrote a paper based on his study of confederacies, ancient and modern, in which he declared that no confederacy could long endure if it acted upon states only and not directly upon individuals. As the time for the convention of 1787 approached, he drew up an outline of a new system of government, the basis of the "Virginia plan," sometimes called the "Randolph plan" because it was presented in the convention by Edmund Randolph.

Madison's scheme, as expressed in a letter to George Washington, April 16, 1787, was that individual sovereignty of states was irreconcilable with aggregate sovereignty, but that the "consolidation of the whole into one simple republic would be as inexpedient as it is unattainable." He considered as a practical middle ground changing the basis of representation in congress from states to population, thus giving the large states a greater voice. He favoured giving the national government "positive and complete authority in all cases which require uniformity" and a negative authority on all state laws, a power he felt might best be vested in the senate, a comparatively permanent body. He also favoured electing the lower house for a short term; providing for a national executive and national judiciary chosen by the legislature; creating a council to revise all laws, and including an express statement of the right of coercion; and finally, obtaining the ratification of a new constitutional instrument from the people, and not merely from the legislatures.

The "Virginia plan" was the basis of the convention's deliberations which resulted in the constitution favourably voted on by the convention on Sept. 17, 1787. Madison, always an opponent of slavery, disapproved of the compromise (in Art. I, sec. 9 and Art. V) postponing to 1808 (or later) the prohibition of the importation of slaves. He took a leading part in the debates of the convention, of which he kept careful notes, afterwards published by order of congress (3 vol., 1843). He spoke before the convention more frequently than any delegate except James Wilson and Gouverneur Morris.

In spite of the opposition of the Virginia leaders, George Mason and Edmund Randolph, Madison induced the state's delegation to stand by the constitution in the convention. To meet the objections brought against it throughout the country, he joined Alexander Hamilton and John Jay in writing *The Federalist*, a series of 85 papers, of which 29 (numbers 10, 14, 18, 19, 20, 37 through 58, 62, 63) were written by him. In the Virginia convention for ratifying the constitution (June 1788), when eight states had ratified and it seemed that Virginia's vote would be needed to make the necessary nine, Madison appeared at his best against

such opponents of ratification as Patrick Henry, George Mason, James Monroe, Benjamin Harrison, William Grayson and John Tyler. Against an originally adverse public opinion and against the eloquence of the opponents of the constitution, Madison and his associates, Edmund Pendleton, John Marshall, George Nicholas, James Innes and Henry Lee, won a significant victory. At the same time, Madison's labours in behalf of the constitution alienated from him valuable political support in Virginia. He was defeated by Richard Henry Lee and William Grayson for the U.S. senate, but in his own district he was chosen a representative to congress, defeating James Monroe.

In Congress and Cabinet.—Madison took his seat in the house of representatives in April 1789, and assumed a leading part in the legislation necessary to the organization of the new government. He drafted a tariff bill giving certain notable advantages to nations with which the United States had commercial treaties, hoping to force Great Britain into a similar treaty; but his policy of discrimination against England was rejected by congress. It was his belief that such a system of retaliation would remove the possibility of war arising from commercial quarrels. He introduced resolutions calling for the establishment of three executive departments—foreign affairs, treasury and war—the head of each to be removable by the president.

Most important of all, Madison proposed nine amendments to the constitution, which were the basis of the Bill of Rights embodied in the first ten amendments. A staunch friend of the constitution, Madison believed that the instrument should not be interpreted loosely. He opposed Hamilton's measures for the funding of the debt, the assumption of state debts and the establishment of a national bank and on other questions. He sided more and more with the opposition, gradually assuming its leadership in the house of representatives and playing a leading role in the formation of the Jeffersonian Republican party. Madison objected to carrying out the recommendations in Hamilton's report on manufactures (Dec. 5, 1791), which favoured a protective tariff.

In 1793-96 he strongly criticized the administration for maintaining a neutral position between Great Britain and France. He wrote for the public press five papers (signed "Helvidius"), attacking the "monarchical prerogative of the executive" as exercised in the proclamation of neutrality in 1793 and denying the president's right to recognize foreign states. He found in Washington's attitude an "Anglified complexion," in direct opposition to the popular sympathy with France and French republicanism. In 1794 he again tried his commercial weapons, introducing in the house of representatives resolutions based on Jefferson's report on commerce, advising retaliation against Great Britain and discrimination in commercial and navigation laws in favour of France; and he declared that the friends of Jay's treaty were "a British party systematically aiming at an exclusive connection with the British Government."

In 1797 Madison retired from congress, but not to a life of inactivity. In 1798 he joined Jefferson in opposing the Alien and Sedition laws, and Madison himself wrote the resolutions of the Virginia legislature declaring that the powers of the federal government were limited by the compact to which the states were parties, and affirming that, in case of a "deliberate, palpable and dangerous" exercise of powers, not granted by the constitution the states had the right and the duty to interpose their power. The Virginia resolutions and the Kentucky resolutions (the latter having been drafted by Jefferson) were met by dissenting resolutions from the New England states, from New York and from Delaware. In answer to these, Madison, who had become a member of the Virginia legislature in the autumn of 1799, wrote for the committee to which they were referred a report elaborating and sustaining in every point the Virginia resolutions.

Madison became secretary of state upon Jefferson's accession to the presidency in 1801. Because of their close relationship it is difficult to separate their roles in the diplomacy of 1801-09. The great achievement was the purchase of Louisiana, and following it, the success with the Barbary pirates. Their failures were the inability to acquire Florida and the hopelessness of the relationship with England and France.

During eight years as secretary of state, Madison had continually to defend the neutral rights of the United States against the encroachments of European belligerents; in 1806 he published *An Examination of the British Doctrine which subjects to Capture a Neutral Trade not open in Time of Peace*, a careful argument against the doctrine set forth by Great Britain in 1756 and extended in 1793 and 1803.

President.—In 1808 Madison was elected president by 122 electoral votes over his Federalist opponent, Charles C. Pinckney, who received 47 votes. Taking office at a moment of crisis in relations between the United States and Great Britain, the first years of his administration were dominated by problems of foreign affairs. For two years the president did the work of his incapable secretary of state, Robert Smith, who was replaced in 1811 by James Monroe.

While many historians have viewed President Madison as a weak and indecisive executive, pushed hesitantly into war by congress, Madison's most exhaustive and critical biographer, Irving Brant, rejects this verdict. Brant depicts a president who led congress and the nation. When his peace policy of economic coercion failed, he aroused public opinion both to change the complexion of congress in the elections of 1810 and to support the War of 1812. The country, however, was not adequately prepared for war, nor was it united in support of what many called "Mr. Madison's War." Re-elected in 1812 in spite of formidable opposition, Madison grew increasingly unpopular as disaster followed the armies (see WAR OF 1812); the New England Federalists called for his resignation and even talked secession. In general, congress was more to blame than either the president or his official family, or the army officers. With the declaration of peace the president again gained a momentary popularity. In the postwar period, Madison assented to a new nationalistic program which included the creation of the Second Bank of the United States and levying a protective tariff.

Retiring from the presidency in 1817, Madison returned to his home, Montpelier, Orange county, Va., which he was to leave in no official capacity except in 1829, when he was a delegate to the state constitutional convention and served on several of its committees. Madison took an interest in education, in emancipation of slaves, and in agricultural questions, to the last. He died at Montpelier on June 28, 1836.

Madison was married in 1794 to Dolley (or Dolly) Payne Todd (1768-1849), a widow of great social charm. Her plump beauty was often remarked, notably by Washington Irving, in contrast to Madison's delicate figure and wizened face. He was, as Henry Adams wrote, "a small man, quiet, somewhat precise in manner, pleasant, fond of conversation, with a certain mixture of ease and dignity in his address." Henry Clay, contrasting him with Jefferson said that Jefferson had more genius, Madison more judgment and common sense; that Jefferson was a visionary and a theorist, Madison, cool, dispassionate, practical and safe. The broadest and most accurate scholar among the "founding fathers," he was particularly an expert in constitutional history and theory.

See also UNITED STATES (OF AMERICA): *History*; and see references under "Madison, James" in the Index.

BIBLIOGRAPHY.—Madison's life is most competently and exhaustively treated in Irving Brant, *James Madison* (5 vol., 1941-56). Older biographies were written by J. Q. Adams (1850), W. C. Rives (3 vol., 1859-69) covering the period before 1797, S. H. Gay (1884), and Gaillard Hunt (1902). Madison's *Writings* (9 vol., 1900-10) were edited by Hunt, who also edited *The Journal of the Debates in the Convention Which Framed the Constitution of the United States*, as recorded by James Madison (1908). Publication of a more extensive collection of Madison's writings, edited by W. T. Hutchinson and R. M. E. Rachal, began in 1962. See also Henry Adams, *History of the United States, 1801-1817* (9 vol., 1889-91); S. F. Bemis, ed., *American Secretaries of State and Their Diplomacy*, iii (1927); N. E. Cunningham, Jr., *The Jeffersonian Republicans* (1958); Adrienne Koch, *Jefferson and Madison: the Great Collaboration* (1950). (N. E. Cu.)

MADISON, the capital of Wisconsin, U.S., the seat of Dane county and the University of Wisconsin, lies in the south central part of the state in a rich agricultural region of gently rolling wooded hills. Four lakes linked together by the Yahara river furnish a picturesque site for the city, located on an isthmus be-

tween the two largest, Lake Mendota (15.2 sq.mi. in area), and Lake Monona (5.5 sq.mi.). Pop. (1960) city 126,706; standard metropolitan statistical area (Dane county) 222,095. (For comparative population figures see table in WISCONSIN: *Population*.) Surrounded by a number of populous communities Madison began a program of annexation about 1940 which by 1958 had trebled its area and accounts in part for the population increase. Two independent residential villages, Maple Bluff and Shorewood Hills, lie within Madison's boundaries. Middleton borders it on the northwest.

History.—Madison was founded in 1836, a year of frenzied speculation in public lands and townsites in the newly created Territory of Wisconsin. The pleasant wooded knoll between the lakes caught the eye of one of Wisconsin's most far-sighted and inveterate speculators, James Duane Doty, who laid out a townsite for a company of investors which included Gov. Stevens T. Mason of Michigan. It was named for Pres. James Madison, who had recently died. That fall Doty lobbied a bill through the legislature, which was then meeting at the temporary capital of old Belmont, making Madison the permanent capital. The place was uninhabited but construction was quickly begun on a capitol and late in 1838 the legislature held its first session in the unfinished building. Controversies over the legal title to the townsite and financial stagnation following the panic of 1837 retarded settlement.

In 1846, when a village government was established, the lonely inland community still numbered only 626 inhabitants. Due in large measure to the efforts of Leonard J. Farwell, the "second father of Madison," small industries soon began to move in. The state university opened its doors in 1849, a railroad reached Madison in 1854, and in 1856 the city was incorporated. Its growth thereafter was unspectacular but steady, following the pattern laid down in early years.

The Economy.—Government operations, federal, state, county and city, account for much of the city's prosperity. Federal agencies include the U.S. forest products laboratory, the first of its kind in the world. The white granite capitol (the third on the site, constructed 1906-17) stands in the centre of the city in a 14-ac. wooded park. Nearby is the county and city building (completed in 1957), and a mile away is the University of Wisconsin, occupying 320 ac. within the city limits and an additional 1,654 ac. in Dane county. (For further discussion of the university see WISCONSIN: *Education*.)

Institutional agencies occupy more than a quarter of the land area of the city. This is divided almost equally among three groups: the city, for schools, parks, government buildings; the state and the university; and semi-public organizations such as churches, hospitals and lodges. The number employed by government agencies in Madison exclusive of educational staffs was estimated at 14,000 in the 1960s.

Industries developed substantially after World War I. In the early 1960s the city had more than 150 industrial plants employing more than 12,000 persons. Because of its central location and good transportation facilities, Madison became a jobbing and distributing centre for the wholesale trade. Truax field, used jointly by the city and the U.S. air force, serves as the commercial airport.

Other Facilities.—Madison is noted for its numerous public and parochial schools, its libraries and its hospitals. There are numerous parks and playgrounds, golf courses, bathing beaches, picnic grounds and other forms of recreational areas in the city. The city has a high proportion of professional, managerial and technical personnel. Its people are a middle-income population.

(AL. E. SM.)

MADIUN (Dutch MADIOEN), the name of a *kabupaten* (regency) of the province of Djawa-Timur (East Java), Indonesia, and of its capital town. Madiun town lies on the banks of the Madiun river, a tributary of the Solo. Pop. (1961) 123,373 (municipality), mostly Indonesians and Chinese. Its chief buildings face the Djalan Raya—the town hall, the Roman Catholic church, the city theatre, the radio station, the post office, hotels, etc. The well-kept Taman Pahlawan, where hundreds of soldiers killed in

the Indonesian revolution are buried, is the pride of the town. Madiun is served by the railway line connecting Jakarta and Surabaya and is connected by road with other towns. The airport is at Maospati, 6 mi. W. of Madiun. The inhabitants of the town are mostly labourers, working in the large railway shop, textile mill, sawmill, cigarette industries, transport, etc. There are also several sugar factories around the town.

MADIUN KABUPATEN has an area of 443 sq.mi. Pop. (1961) 509,428. In the north and centre are fertile plains. To the east and west are high volcanic groups, including Gunung Liman (8,335 ft.) and Gunung Lawu (10,712 ft.). There are limestone ranges to the south, forming a difficult coast without a harbour. Rice and sugar cane are the principal crops, supplemented by maize, cassava, coffee, cacao, cinchona, coconuts and peanuts. Teak is obtained from the forests. Under Dutch occupation, Madiun was a residency, with an area of 2,512 sq.mi. After creation of the republic the residency was broken up and the *kabupaten* of Madiun created. (D. So.)

MADRAS, a state of the Republic of India, lies in the south of the Indian peninsula and includes Cape Comorin, the southernmost point of the whole country. It is bounded on the northeast by Andhra Pradesh, on the northwest by Mysore and on the southwest by Kerala. Under British rule Madras presidency was one of the major provinces and stretched northward along the coast to the borders of Orissa. With the coming of independence in 1947 the northern Telugu-speaking districts were constituted into the state of Andhra Pradesh, leaving Madras state to include only the Tamil-speaking districts or Tamilnad. Under the States Reorganization act, 1956, the districts of Malabar (excluding the Laccadive and Minicoy Islands), the South Kanara district (excluding Kasargod *taluka* and Amindivi Islands), and the Kollegal *taluka* of Coimbatore district were transferred to Mysore state, the Laccadive, Minicoy and Amindivi Islands being constituted into a centrally administered territory. In return Madras gained four *talukas* of Trivandrum district (later constituted as Kanya Kumari district; *q.v.*) and the Shencottah *taluka* of Quilon district (now part of Tirunelveli district) from the old Travancore-Cochin state. The Andhra-Madras (alteration of boundaries) act, 1959, drafted on the Pataskar Award, came into force on April 1, 1960. Under this act, 319 villages in Tiruttani, Chittoor and Puttur *talukas* of Andhra Pradesh (area 405 sq.mi.) were exchanged for 151 villages in Tiruvallur, Ponneri and Hosur *talukas* of Madras (326 sq.mi.).

Madras, thus reorganized as a compact and homogeneous state, has an area of 50,331 sq.mi. The state capital is Madras.

Physical Features.—On the northwest the boundary with Mysore coincides roughly with the edge of the great Indian plateau, an edge known as the Eastern Ghats and rising in parts to more than 3,000 ft. In the extreme west the state includes the mountain mass of the Nilgiris separated from the southern end of the plateau by a deep trough and rising in Mt. Doda betta to 8,640 ft. overlooking the hill station of Ootacamund (Ooty). Southward of the Nilgiris and their spur, the Vellangiri hills, is the Palghat gap which affords a main routeway to the west coast. South of the gap and forming the boundary between Madras and Kerala are the Cardamom hills. Broadly speaking Madras comprises the land between this succession of heights on the west and the shallow shelving shores of the Bay of Bengal and Gulf of Mannar on the east. The western half is rolling or hilly country with settlement and cultivation in the valleys, giving place to the eastern half occupied mainly by alluvial plains. Nearly all the drainage is to the east, by a number of small streams in the south, by the important Cauvery (Kaveri) system in the centre (with a large alluvial delta), by the Penner or Ponnaiyar and the Cheyyar-Palar systems in the north.

The hill country consists of outliers of the old crystalline rocks of the plateau, with important mineral deposits in places; there are three detached areas of marine Cretaceous deposits near the coast.

The climate of Madras differs markedly from that of other parts of India since the main rainy season is in October–December—the season of the “retreating monsoon.” The whole of the

coastlands receive more than 10 in. in the two months November–December, and practically the whole state more than 5 in. In that part of the coast north and south of Madras city the total annual fall exceeds 40 in. but inland it drops, in places to only a little over 20 in. and that somewhat irregular. Consequently irrigation is needed not only for water-demanding crops such as rice but also to secure a certain harvest for such dry-zone crops as cotton and millet. Many of the small river valleys are dammed to provide “tanks” and there are important irrigation works on most of the rivers, many of great antiquity. In Kerala on the western side of the Cardamom hills, the rainfall is heavy: there the upper valley of the Periyar river was dammed and the water brought through by a tunnel to the dry Madras side. As might be expected from the southern situation the annual range of temperature is small—in Madras city from a May average of about 32° C. (a little under 90° F.) to a January average of 24.4° C. (76° F.). (L. D. S.)

History.—Madras state, as established in 1956, is confined to the Tamil-speaking areas of the old Madras presidency, the Telugu-speaking areas having been transferred to Andhra Pradesh (1953 and 1956), the Kanarese-speaking area to Mysore and the Malayalam-speaking districts to Kerala. It does not, however, correspond with any historical political subdivision of India.

For the ancient dynasties which disputed rule over southern India reference should be made to the articles CHOLA, PANDYA, KERALA and CEYLON. The Tamil civilization (out of which Malayalam civilization developed) is probably older than the Aryan, but it is difficult to isolate pure Dravidian elements even in the literature patronized by the earliest historical Tamil kings. The Chola-Pandya country, not less than Malabar, long enjoyed Greco-Roman trade, but Hellenistic culture made practically no impact since Abyssinians or Arabs monopolized the traffic. Tamil and Telugu influence upon southeast Asian cultures is more noticeable. The successive hegemonies of the Cholas and the Pandyas (subject to Hoysala incursions) gave way to a fragmentation, in which Andhra and even Oriya rulers shared northern Madras with Pandyas, Yadavarayas and Sambuvarayas, preparing the way for Muslim raids, the foundation of the sultanate of Madurai (*c.* 1340–78) and the conquest of all competitors by Vijayanagar (*q.v.*). Even after 1565, when Vijayanagar was virtually confined to the Karnataka portion of the Deccan, that empire was supreme in the Tamil country, giving it the misleading name “Carnatic,” the other corruption, Coromandel (*Chola-mandalam*), being more satisfactory.

The *nayakas* (nayaks) or district governors became virtually independent by the mid-17th century, and when the French and British superseded the Dutch they were able to meddle in the nayaks' rivalries. The British who had established a trading post at Peddapali (now Nizampatam) in 1611 settled at Madras (Pt. St. George) in 1639, and the French acquired Pondicherry in 1674. Interested in trade and in expanding the scope of Christianity (Nestorian churches existed on the eastern coast from antiquity), they were already implicated in Tamil politics when the Moguls created the nawabship of the Carnatic, the nawab at Arcot being the deputy of the nizam of the Deccan. Incursions of the Marathas into the Tamil country embarrassed the nawab. By the mid-18th century the local rulers needed European help, and wars in Europe gave point to British and French competition for the openings which developed. The Marathas set up a kingdom at Tanjore (Thanjavur). The British took a lease from the nawab in 1763 of the modern Chingleput district, in which Madras is situated. While the East India company was concerned to control the Carnatic without actually ruling it, by delicate relations with Arcot and Tanjore were complicated by money lending on the part of servants of the company with the rulers themselves. A somewhat discreditable chapter in Anglo-Indian history is mitigated by the fact that the Mysore wars rendered improbable the resurgence of local rulers in Madras. Hostilities with the French, in which British success is largely to be attributed to sea power, spurred the latter on to force local rulers to become dependent upon them. In 1746 Madras surrendered to Mahé de la Bourdonnais, but it was recovered by

the British at the peace of Aix-la-Chapelle (1748) and Robert Clive's defense of Arcot in 1751 turned the tide in their favour. The defeat of Joseph Dupleix, governor general of the French establishment, was paralleled in 1760 by Col. (later Sir Eyre) Coote's victory of Wandiwash over the Comte de Lally. Pondicherry was taken in 1761. The Northern Circars region was granted to the Madras government in 1766. A revival of French power through the nizam and Mysore was feared during the revolutionary and Napoleonic wars. The Mysore wars of 1790-92 and 1799 brought territory on the west coast, and on the north and south of Mysore, to the presidency. Tanjore, which had been ruled by rajas who combined enlightened orthodoxy with tolerance of western culture, but had become inextricably involved in debt, passed to British administration in 1799. In 1801 a puppet nawab of the Carnatic resigned his dominions into British hands.

British administration was at first disturbed by the remoteness of the southern and western regions, the independent temperament of the *poligars* (hill chiefs), the power of predatory tribes and the results of centuries of fear of armed invasion from the north. The Madras presidency, with the rest of British India, was under the direct rule of the British crown from 1858 to 1947. The British period saw the arrival of western science, philosophy, law and letters, to all of which Madrassis contributed, while in music and the indigenous arts Madras remained pre-eminent in India. In the religious and moral field western influence ennobled and confirmed (by example and by contrast) Indian traditions. Settlement of land revenue was largely direct with the cultivators. The government undertook irrigation and public works on a large scale. The public were not violently opposed to foreign rule. Prejudice in favour of Brahmanical culture discouraged more ancient ways, such as those in force in Malabar. The educational prowess of Brahmans led to a long prevailing anti-Brahman feeling. Hindi made rapid progress.

Trade-unionism and co-education made their first strides in Madras state. Conservative elements, after 1947, included the international traders, the Chettyars. Tamil "nationalism" was exemplified in the party called the Dravida Munnetra Kazhagam. (See also INDIA-PAKISTAN, SUBCONTINENT OF.)

(J. D. M. D.)

Population, Administration and Social Conditions.—

Madras had a population (1961) of 33,686,953, the vast majority of which are Dravidians. The chief cities and towns, with their populations according to the 1961 census, are: Madras (1,729,141), Madurai (424,310), Coimbatore (286,305), Tiruchirapalli (249,862), Salem (249,145), Tuticorin (124,230), Vellore (113,742), Thanjavur (111,099), Nagercoil (106,207), Dindigul (92,547), Kancheepuram (92,714), Kumbakonam (92,581), Tirunelveli (87,988), Tiruppur (79,773), Cuddalore (79,168), Erode (73,762), Rajapalayam (71,203), Nagapattinam (59,063).

Executive power is vested in the governor (appointed by the Union president) who acts on the advice of a council of eight ministers. The bicameral legislature comprises a council of 63 members and an assembly of 206 members. Tamil is the principal and state language. The state is divided administratively into 13 districts: Madras; Chingleput; Arcot (North and South); Salem; Tiruchirapalli (formerly Trichinopoly); Thanjavur (Tanjore); Ramanathapuram (formerly Ramanad); Tirunelveli (formerly Tinnevely); Madurai (Madura); Coimbatore; Nilgiris; and Kanya Kumari.

According to the 1961 census 45% of the male and 18% of the female population were literate. There are two universities, Madras and Annamalai, over 200 colleges, more than 23,300 primary schools and about 7,400 schools for general, vocational and technical education. Free primary education is in force in about 1,300 towns and villages. Every village with 500 people has a school and more than 8,000 schools provide free midday meals to children.

There are about 780 hospitals and dispensaries, and many primary health centres in rural areas provide free medical relief, maternity and child health facilities, health education, sanitation and antimalaria measures. Contributory social insurance covers

risks of sickness, maternity, employment injury and general medical care for more than 160,000 factory workers. The State Social Welfare board provides free crèches, elementary schools, training in literacy for adults and crafts-training facilities for women in more than 600 villages. (S. CH.; S. B. L. N.)

The Economy.—Nearly two-thirds of the people of the state are engaged in agriculture. The principal food staples are rice and cholam, cambu, ragi and varagu (four kinds of millet). The most common oilseed is peanut. Sugar is derived from cane and the sap of palms. The principal fruit trees are coconut, areca nut, jack, tamarind and mango, and other crops include coffee, rubber, tobacco and tea. Excellent cotton is grown mostly in the western district. Coffee growing has suffered from fluctuating fortunes due to disease but is again an important crop in the Nilgiris together with tea. The greater part of the soil is held by the cultivators direct from the government under the tenure known as ryotwari.

The most important irrigation plan is the Perambikulam-Aliyar project (started in 1958), which would, when complete, irrigate about 250,000 ac. of land.

Forests cover more than 6,500 sq.mi. mainly in the hilly western areas where teak is an important tree. Other forest products are ebony, rosewood, sandalwood and redwood as well as quantities of bamboo. There are plantations of wattle, eucalyptus and cashew.

The mineral wealth of the state is largely undeveloped, though excellent iron has been smelted by local smiths from early times. The principal minerals are mica, barite, gypsum, bauxite, limestone, china clay, magnesite, etc., and lignite is mined at Neyveli in South Arcot district. Ilmenite and monazite deposits occur in Kanya Kumari district. Steel tubes are manufactured at Avadi, and a pig iron plant is in production at Coimbatore.

The chief industries in Madras are cotton ginning, spinning and manufacturing, coffee curing, rice milling, oil pressing, rope-making, sugar refining, tanning, tile- and brickmaking, and the manufacture of bicycles, cement, glass, matches, salt and soap. The bicycle factory at Ambathur near Madras city is one of the largest of its kind in India. There has been considerable development and diversification of industry since independence. Much depends on hydroelectric power and by the early 1960s about half the villages of Madras were linked to the state power grid.

Communications.—The coast of Madras suffers from a shallow-shelving shore with no good natural harbour and dangerous surf through much of the year. The digging of the Buckingham salt-water canal running for 250 mi. close to the coast north and south of Madras city was an early attempt to help coastwise shipping, and it serves to link a number of small ports. With the completion of the deepwater harbour of Madras in 1909 the bulk of the overseas trade became concentrated there. The chief staples of the export trade are cotton and cotton piece goods, peanuts, hides and skins, tea and coffee, coir manufactures, rice and oil.

The state is well supplied with railways, which naturally have their centre in Madras city, the chief seaport. The broad-gauge line of the Southern railway connects with Bombay and Bangalore and also crosses the peninsula to Kozhikode (Calicut) and Mangalore on the west coast. The railways to the south of Madras city are metre gauge. Good motor roads now connect the main cities which include Madurai, Tiruchirapalli, Salem, Coimbatore and Tuticorin. (L. D. S.)

MADRAS (Tamil CHENAI), the capital and chief port of the state of the same name, lies on the eastern coast of India, 850 mi. S.W. of Calcutta. Pop. (1961) 1,729,141. The city was

founded in 1639 when Francis Day, head of the English East India company's trading station at Armagon (Armagaum), which was concerned chiefly with the cloth trade, obtained a strip of land known as Madraspatam, or Madraspatnam, to the north of San Thomé and Mylapore. He got permission to build a fort there and this was completed in 1639 on St. George's day which probably accounts for its being called Ft. St. George. The town of Madras grew up round the fort and by 1641 it had become the company's headquarters and the chief English trading station on the Coromandel coast. In 1746 it was captured by the French who retained it until 1748, when it was returned to the English under the treaty of Aix-la-Chapelle. The corporation of Madras, the oldest in the east, was granted a charter under the East India company's seal in 1687. In 1871, with an area of 27 sq.mi., it was no more than a loose agglomeration of several distinct urban areas, a characteristic which in some parts it still retains. By 1931 the area had increased to 29.5 sq.mi.

The Cooum river cuts the city into two almost equal halves. The Adyar river runs 3 mi. S. of the Cooum and the Buckingham canal connects the Cooum with the Adyar. The centre of the city, George Town, to the north of Ft. St. George, is hopelessly congested, as also are some of the older parts in Triplicane and Mylapore, as compared with the newer extensions like Gandhinagar and Kasturbanagar, which have a pleasant rural appearance. Viewed from the air Madras looks quite green, since, even in the most overcrowded parts, there are fine trees, gardens and parks.

The main buildings include the high court (1892; Hindu-Saracenic style), the lighthouse (1889, 160 ft. high, with a revolving light), the Madras museum (1854) and the public library (1896). Madras is a centre of higher learning and research. At Adyar, a suburb, is the international headquarters of the Theosophical society. Madras university, founded with those at Bombay and Calcutta in 1857, is among the oldest in India, but there were English educational institutions even earlier: the Engineering college, the Medical college, the Madras Christian college (moved in 1937 to Tambaram) and the Presidency college. There are also a dozen institutions for arts and science. The university is federal in character, both affiliating and teaching, with more than 120 affiliated colleges throughout the state. In addition to the 30 research departments of the university and two colleges of technology, there are centres for leather research, textiles and preventive medicine.

For Indian Christians Madras is a very sacred spot; names like San Thomé and St. Thomas mount, both within the city limits, bring home its close association with the apostle St. Thomas, who is believed to have met with martyrdom in A.D. 53 at the hands of the king of Mylapore. The city has a large number of churches, ancient and modern; these include the chapel at the top of St. Thomas mount, built in 1514 under orders of King Emanuel of Portugal, the Luz church (1516), San Thomé cathedral (1557; the traditional burial place of St. Thomas), St. Mary's Church in Ft. St. George (1680), the Roman Catholic cathedral (1775), St. Andrew's Scottish kirk (1821), and St. George's cathedral (1816; Church of South India). Madras is the seat of a Roman Catholic archbishop and of an Anglican (South India) bishop.

The Port.—The port has an artificial harbour formed by masonry groynes extending eastward into the sea. The coastal current from north to south erodes the tract of Royapuram, to the north of the harbour abutment, and the sediment so brought down is effectively redeposited to the south, in Triplicane and Mylapore, to produce a fine beach, stretching uninterruptedly for about 6 mi., with an average width of 200 yd. The construction of the harbour started as a screw-pile pier in 1862; in 1876 the harbour proper was completed, to be destroyed by a cyclone in 1881. Its immediate reconstruction was finished by 1896 and it was further remodeled in 1901. It accommodates 18 vessels, 9 at moorings and 9 at quays, the depth at the moorings ranging from 28 to 31½ ft. and at the quays from 26 to 30 ft. In the mid-1960s attempts were being made to enlarge the harbour to cope with the increasing traffic, which includes the export of hides and skins, peanuts and manganese ore and the import of various commodities.

Industries and Communications.—The city's multifarious industries include cotton-weaving (the Buckingham and Carnatic mills were opened in 1874), the Railway Integral Coach factory (1953), motion picture production (1930), the manufacture of bicycles (1950) and assembly plants for automobiles and motorcycles (1950). * It is the largest commercial centre and the main newspaper publishing centre of south India.

Madras can be reached by sea, rail, road and air. Ships of all countries call at the port, and the city is the headquarters of the Southern railway, with lines to all parts of the country. All the southern trunk roads converge on Madras. The international air port is at Meenambakkam, 10 mi. from the city, with connections to Singapore, Sydney, Australia and Colombo, Ceylon and internal services to the principal cities of India. (G. Kn.)

MADRAZO, a family of Spanish artists.

JOSÉ DE MADRAZO Y AGUDO (1781–1859), portrait and history painter and etcher, was born at Santander, April 22, 1781, and died in Madrid, May 8, 1859. A supporter of Charles IV, he followed the king to France after his abdication in 1808 and became a pupil of J. L. David, whose influence shows clearly in his portraits. He went to Rome, and in 1819 returned to Madrid, where he was appointed keeper of the Prado and director of the Academia de San Fernando.

FEDERICO DE MADRAZO Y KUNTZ (1815–1894), portrait and history painter, José's eldest son, was born in Rome, Feb. 9, 1815, and died in Madrid, June 10, 1894. He was a pupil of his father, of the Academia de San Fernando and of F. Winterhalter in Paris (where J. A. D. Ingres was among his portrait subjects). His "Godefroy proclamé roi de Jérusalem" was commissioned for Versailles in 1837. After a long stay in Rome he returned to Madrid as a fashionable portraitist, becoming painter-in-ordinary to the court and in 1859 succeeding his father in the direction of the Prado and the Academia. He was the founder of *El Artista*, *El Renacimiento*, *El Semanario pintoresco* and other journals.

José's second son, LUIS DE MADRAZO Y KUNTZ (1825–1897), was a successful history painter, and his youngest son, JUAN DE MADRAZO Y KUNTZ (1827–1880), was architect of the English church and other buildings in Madrid. RAIMUNDO DE MADRAZO Y GARRETA (1841–1920), Federico's eldest son and pupil, was a portrait, subject and genre painter who eventually settled in France. Federico's youngest son and pupil, RICARDO DE MADRAZO Y GARRETA (1852–1917), also a pupil of Mariano Fortuny, was a genre painter and sculptor.

MADRE DE DIOS, a montaña department of southeastern Peru, bounded north by Brazil and Loreto, east by Bolivia, west by Cuzco and south by Puno. Area 30,271 sq.mi.; pop. (1961) 14,828. The department, created in 1902, is an isolated region of dense forests subject to periodic inundation. The climate is generally hot and humid with heavy rainfall; however, there is a fairly well-marked dry season from April through September. Economic resources of the department comprise rubber of the high-quality Beni-Acre type, Brazil nuts, medicinal plants and hardwoods. Crops cultivated include rice, cassava, bananas, sugar cane and other tropical commodities.

Puerto Maldonado, pop. (1961) 3,536, capital of the department, is situated at the confluence of the Madre de Dios and Tambopata rivers. It may be reached by air but otherwise transport is by river craft. The population is largely Indian and mestizo with a small colony of Japanese. (J. L. Tr.)

MADRE DE DIOS RIVER rises in the Cordillera de Carabaya near Paucartambo in southern Peru and flows 615 mi. north and northeast past Manú in Peru and Puerto Heath on the Peru-Bolivia border to meet the Beni river at Riberalta, Bol. The Beni and Mamoré unite northeast of Riberalta to form the Madeira river, one of the major tributaries of the Amazon. In Peru the Madre de Dios flows through the sparsely settled department of Madre de Dios. The Madre de Dios river is generally navigable for small craft on the upper course but its efficiency, like that of most rivers in eastern Bolivia, is much reduced by rapids and tree trunks. Traffic on the river is interrupted just below Puerto Heath.

During the days of the rubber boom in the Amazon basin there

were numerous rubber stations on the Madre de Dios, but after 1922 production ceased to be commercially important. The climate is hot and humid and the entire region is largely covered with virgin forest. There is still some gathering of rubber, balata, chicla and other products along the river's course. In a few small areas there is some unimpressive production of cacao, coffee, cotton, fruits, sugar cane and cassava. Development of this isolated area through which the Madre de Dios flows does not appear likely, but the river is the main communication line with the outside world. (L. W.E.)

MADRID, a province of central Spain formed from districts included before 1833 in New Castile. Area 3,087 sq.mi.; pop. (1960) 2,606,254 (including the city of Madrid, pop. 2,259,931 [mun.]). The province roughly coincides with the drainage of the southern slopes of the Sierra de Guadarrama (7,972 ft.), i.e. the Jarama, Henares and Manzanares rivers. From the precipitous southern flanks of the Guadarrama, the relief descends to the gravel pediments that floor a series of lower platforms, merging into the gentle, rolling relief of Tertiary sediments. Miocene clays and sands cover most of the southern half of the province cut into by well-developed series of river terraces. Pine forests, preserved on the mountain slopes, now attract a new style of summer suburbia for the people of Madrid, but otherwise it is a bare, typically Castilian landscape of yellow soils and open cereal fields. Only along the Henares and Jarama do irrigated lands give a ribbon of green, intensive horticulture and on the outskirts of greater Madrid are poultry and pig farms interspersed with the ribbon development of villas or new factories. Chamartín, Carabanchel, Pueblo-Ventas and even Getafe already form part of greater Madrid. The province is well endowed with building materials, granite quarries in the Guadarrama, brick and tile works exploiting the clays to the south. The city's water supplies come from the headstreams of the Jarama and its affluents; the aqueduct, Canal del Lozoya (56 mi.), was first made in 1855 but has been much expanded.

An important factor in the growth of communications is the relative ease of passes over the central Cordillera. The easiest is the Somosierra (4,650 ft.) to the northeast, utilized by road and the new Burgos railway. The Puerto de Navacerrada links the Madrid-Segovia road. All the great national railways converge in this province which contains 221 mi. of line. (J. M. Ho.)

MADRID, the capital of Spain and Madrid province in New Castile, lies almost in the centre of the Iberian peninsula. Pop. (1897) 397,816; (1950) 1,571,939; (1960) 2,259,931.

The highest capital city of Europe, it is situated on the Meseta, an undulating plateau of sand and clay. On the northwest, beyond the Manzanares river (a 50-mi.-long tributary of the Jarama, which flows into the Tagus), the city is bounded by heath and parkland, the former comprising the royal hunting preserves (Casa de Campo); farther north is the Sierra de Guadarrama (7,972 ft.), the inner valleys of which, still fairly well wooded, are much frequented by the *Madriños*. On the other sides Madrid is surrounded by agricultural land, mostly treeless and bare in appearance, but well cultivated. The highest point in Madrid is 2,373 ft. above sea level. This altitude and the open situation of the town makes it liable to sudden variations of temperature. On the other hand, to these same circumstances Madrid owes its clear, pure atmosphere which makes its climate healthful and reasonably pleasant except in July and August, when the heat becomes oppressive.

The Moorish name of the town (Majrit), first historical evidence of its existence, appears to have been mentioned in 932 when Ramiro II razed its walls but left it in Moorish hands. Traces have been found of a Roman settlement and even some indications of human habitation in prehistoric times. Nevertheless, Madrid must be considered a modern town by Spanish standards, and only gained some claim to fame when Alfonso VII granted it certain privileges. The parliament (*Cortes*) was twice summoned in Madrid (1309 and 1478). Henry III, John IV of Portugal and Henry IV of Castile all spent considerable periods of time in the town, where the latter king died. Philip II, taking into account its central position and healthful surroundings, established his

capital there in 1561, a decision generally thought to be transitory. In fact, it was only in 1607, under Philip III, that Madrid finally attained its present status. During the War of the Spanish Succession, Madrid took the Bourbon side against the Habsburgs. In 1808 it gave the signal for a mass uprising against the troops of Napoleon, remaining afterward obdurately hostile to his brother Joseph, whom he had placed on the Spanish throne. Ferdinand VII, on his return from imprisonment by Napoleon in 1814, bestowed upon the town the title of "heroic." As a consequence of the political vicissitudes of the 19th and 20th centuries the life of the capital was disturbed more than once. The disturbances remained sporadic until the Spanish civil war of 1936-39, when, as seat of the government, Madrid became the scene of the two-and-a-half years' siege, which ended on March 28, 1939, with the entry of the nationalist troops. All traces of the damage suffered were completely obliterated.

Madrid is the see of a bishopric, the headquarters of an army corps and residence of the captain general of the 1st military region, the focus of the main roads and railways, a banking centre, the seat of a university, of the supreme court and of all branches of the central administration. The head of the state lives in the former royal palace of El Pardo, 9 mi. from the city proper. Economically the importance of Madrid considerably increased. In the 1960s it was the second Spanish industrial town after Barcelona.

Development and General Description.—Madrid has known four well-defined periods of development: the first, under the house of Austria, shortly after having been chosen capital; the second, under Charles III (1759-88), one of the so-called enlightened despots; the third stretching from the end of the reign of Isabella II (1868) to the regency of Maria Cristina of Habsburg (1885-1902); and the last, which includes World Wars I and II, interrupted by the Spanish civil war of 1936-39.

From the first period dates the Plaza Mayor, built in 1619, rectangular in shape and 430 ft. long, ornamented by an equestrian statue of Philip III and two small fountains. It has witnessed many a solemnity, from tournaments to bullfights and autos-da-fé. To the same period also belong the building housing the foreign office, the remnants of the royal palace of El Buen Retiro (an artillery museum) and the town hall. To Charles III are due the Puerta de Alcalá, one of the two city gates worthy of mention (the other being the Puerta de Toledo), the finance ministry and the observatory. He also completed the royal palace, constructed in 1735-64 by Filippo Iuvara and G. B. Sachetti. The middle of the 19th century saw the opening of a new opera house (Teatro Real, 1850), the installation of water mains (1858) and the construction of the square known as Puerta del Sol.

José de Salamanca, a prominent banker, gave a new impetus to the extension of Madrid, by planning and financing the fashionable district bearing his name. From 1900 progress continued at a steady but leisurely pace. In 1910 the opening, through a maze of old streets, of the commercial thoroughfare popularly called Gran Vía took place. Roughly one mile long, it became a smart shopping and amusement centre and altogether changed both the face and the tempo of life of central Madrid. Flanked by tall modern buildings including the 14-story telephone exchange, the Gran Vía ends at the Plaza de España, where stand the Cervantes monument and the España skyscraper, reputed to be the tallest in Europe.

In 1919 the first subway was opened. From that time the town's growth has been swift and constant. Between 1947 and 1951 nearly all the outlying suburbs were annexed to the capital and the municipal territory increased tenfold. A planning organization, the Comisaria Superior de Ordenación Urbana, was created. Developments after 1939 included reconstruction of the university city, destroyed during the civil war; new canalization of the Manzanares, thereby reclaiming further land along its banks, where a vast scheme of working-class dwellings, green spaces and artificial beaches has been carried out; the erection of the group of buildings housing the Higher Council for Scientific Research; and the construction of the Barajas international airport, linked with the capital by a magnificent highway. The Castellana avenue

was prolonged for nearly a mile, the main roads leading into the town widened and embellished, a new ring road constructed and several important housing schemes, comprising blocks of flats (Barrios de la Concepción, de la Quintana, del Niño Jesús, etc.) and suburban garden cities (Puerta de Hierro, la Florida), completed. Other municipal developments included an extension of the subway, replacement of streetcars by buses and trolley buses, improvements in sanitation and lighting, and new athletic fields, including the gigantic Chamartín stadium.

In the course of its somewhat haphazard growth Madrid has become the common modern type of sprawling city and has therefore no definite form, the only feature retained of its previous shape being that it still measures rather more from north to south than from east to west.

The Puerta del Sol (reputedly named after a gate, which stood there until 1510 and had on its front a representation of the sun) used to be the centre of Madrid and the busiest spot. Devoid of all architectural interest, it has become peripheral, and several other centres have sprung up in different parts of the town. On the north side of the Puerta stands a square red brick building erected in 1768 as a post office, later the police headquarters. The three-mile-long Calle de Alcalá starts in the Puerta del Sol. It contains the finance and education ministries, a theatre, two churches, nine of Spain's main banks and the Real Academia de Bellas Artes, founded in 1752 as an academy of art and music. Its collection of Spanish masters includes some of the best works of Murillo and Goya.

The Bank of Spain stands where the Calle de Alcalá intersects the Prado, an avenue laid out with gardens and adorned on the right side by the fountain of Apollo and on the left by an obelisk commemorating the rising against Napoleon. The Prado connects two oval plazas in each of which is a fountain, one representing Neptune and the other Cybele. At one end of the avenue stand the Prado museum and the Church of St. Jerome (founded by the "Catholic Sovereigns" Ferdinand and Isabella and the scene of royal weddings and ceremonies); at the other the general post office (1916) and the ministry of marine; in the middle the exchange (1894). The Paseo del Prado has great architectural distinction, bounded on one side by a residential quarter including the Retiro gardens, a park with ponds, fountains, monuments and a zoo. A royal palace, built for Philip IV and destroyed during the French occupation, once stood there.

Northward the Prado is continued by the Calvo Sotelo (formerly the Paseo de Recoletos) and the Castellana, in which are the national library, the mint, the Columbus monument, foreign embassies and residences of the aristocracy and the well-to-do.

Near the Puerta del Sol lies the Plaza de Oriente. A statue of Philip IV on horseback, designed by Velázquez, presides over its gardens, the whole dominated by the royal palace, built on an eminence overlooking the Manzanares. It replaces the old Alcázar,

which burned down on Dec. 28, 1734, and contains richly decorated rooms, a priceless library, collections of tapestries and a famous armoury. Southeast of the plaza and down to the Manzanares stretch the *barrios bajos*, Madrid's most typical and poorest section.

Among the churches the following deserve mention: San Francisco el Grande (18th century, designed by Francesco Sabatini); San Andrés (17th century), one of the finest, which was set on fire by the mob and gutted in 1936; Capilla del Obispo (Gothic and Renaissance, 1520); San Pedro (Hispano-Moorish), built on the site of a mosque; Montserrat (baroque); Comendadoras and San Plácido (both 18th century); and, lastly, San Isidro, used as a cathedral since 1885 (built from 1623 to 1665).

Of secular buildings, the following are notable: the Casa de Cisneros (plateresque); the Casa de los Lujanes, where Francis I of France, captured at Pavia, was kept prisoner; and above all the Prado museum, originally planned as a museum of natural science and formally opened in 1819. The building was designed by Juan de Villanueva, as were the entrance to the adjoining botanic gardens and the nearby observatory. In the Prado are exhibited the paintings collected by the Spanish monarchs from the 15th century, representing almost the entire range of western painting, mainly Spanish, Flemish and Italian, up to the 19th century. A new wing was added in 1956. There are 20 other museums in Madrid, some of them first class: archaeological, artillery, naval and decorative arts museums among them. Of the private collections three are outstanding, namely the Lázaro Galdiano, Cerralbo and Valencia de Don Juan. The Toledo and Segovia bridges (1735 and 1584) spanning the Manzanares are worthy of note.

Education and Culture.—Until 1836, when the university founded in Alcalá de Henares by Francisco Cardinal Jiménez de Cisneros was transferred to the capital, Madrid had no university of its own. Older existing institutions, such as the Medical College of San Carlos (1786) and the Royal Institute of San Isidro, were merged with it, and the University of Madrid became the foremost university in Spain. Among the buildings in the reconstructed university city are several newly created *colegios mayores* or students' residences. Madrid also contains teachers' training colleges, schools of arts and crafts, a conservatory of music, colleges of agriculture, architecture and engineering, etc. The principal learned societies are the royal academies for the cultivation of the Spanish language, of history, moral science, jurisprudence, medicine and pharmacy, mostly created in the 18th century and later incorporated into a body called the Institute of Spain.

From the time it was made a capital Madrid has had a vigorous and lively cultural life. The atmosphere of the town, its light and colour, the temperament of its people, generous, quick-witted, easygoing, even if perhaps superficial, form the background of the literary trend known as *Madridenismo*, which extols the capital's charms and explores its past and present; the writers Ramón de Mesonero Romanos, in the 19th century, and later Ramón Gómez de la Serna being its main exponents. The so-called *zarzuela* ("musical comedy") and *sainete* ("light prose comedy") based on Madrid lore are the outcome of the same feeling.

Industries.—In 1900 Madrid was almost exclusively an administrative and commercial centre. Industries making luxury and fancy goods, pharmaceutical products, leather articles, furniture, etc., began to develop. After 1940, however, Madrid took its place among Spain's chief industrial cities and there are important factories manufacturing aircraft, radio and electrical equipment of all kinds (including domestic appliances), rubber, plastic, optical equipment, trucks and motor engines.

MADRIGAL, the name given to a form of concerted vocal music, Italian in origin. The earliest school of madrigal writing

BY COURTESY OF THE SPANISH NATIONAL TOURIST OFFICE

THE ROYAL PALACE BUILT DURING THE 18TH CENTURY ON THE WEST SIDE OF THE PLAZA DE ORIENTE, MADRID

flourished in northern Italy in the 14th century and is quite distinct from the later one that began about 1530. The early madrigal, like the ballade or the ballata, is a poetical form as well as a musical one. Two or three strophes of three lines each are followed by a final ritornello of two lines; in each strophe two lines rhyme with one another. For this type of madrigal the suggested derivation from *mandria* ("sheepfold") may well be correct, since early writers associate it with the *pastourelle* of the troubadours and its subject matter is generally idyllic and contemplative, if not exactly pastoral. The principal composers in this form were Jacopo da Bologna and Giovanni da Cascia (or da Firenze); their settings are for two or three voices, of which the topmost is usually very ornate.

The madrigal was already becoming obsolete by the time of Francesco Landini (d. 1397) and it fell into complete oblivion during the 15th century. When it was revived by the humanistic circle that gathered about Cardinal Pietro Bembo in the early years of the 16th century it is probable that, whatever its original derivation had been, *madrigale* was thought of simply as equivalent to *matricale*, meaning "in the mother tongue"; i.e., Italian and not Latin, for it is applied to poems without any fixed form. The madrigals of this period were intended as a literary return to the more elevated style of antiquity, in contrast to such current forms as the *frottola* and the *strambotto*. The music to which they were set was likewise intentionally dignified, and it drew upon the style of the contemporary sacred motet and upon Josquin Després's sonorous chansons; nevertheless the break was not a sudden one, and the first of these madrigals (published in 1533) are still similar to *frottole*.

The earliest group of 16th-century madrigal composers includes Philippe Verdelot, Jakob Arcadelt, Adriaan Willaert and Costanzo Festa. It will be noted that northern (French and Flemish) composers preponderate, and it was not until the middle of the century that native Italian composers began to play a large part in the composition of madrigals. Whereas the earlier madrigalists had aimed at a placid, almost abstract, musical accompaniment to the words, Cyprien de Rore, Andrea Gabrieli, Philippe de Monte and Orlando di Lasso cultivated a new and detailed expressiveness, with words such as *acerbo* ("bitter"), *ira* ("anger"), *pianti* ("weepings") underlined by dissonances, and *gioia* ("joy") or *riso* ("laugh") set to swiftly running figures. Although the application of these expressive symbols at times appears naïve, the result was the rapid development of a new musical language, one that had repercussions on the setting of words to music throughout Europe.

The final stage of the Italian madrigal, although it produced much superb music, can be seen as a decline from this intimate fusion of music and poetry. In the hands of such composers as Luca Marenzio, Carlo Gesualdo and Claudio Monteverdi the musical language of the madrigal became ever richer and more varied, but with this went a tendency to set stilted and epigrammatic poems of negligible literary value. The increasing independence of the separate voice parts eventually resulted in the complete breakup of the old polyphonic texture; in the later madrigals of Monteverdi, for example, passages for one or more solo voices are punctuated with sonorous passages for the full group, and unity is achieved not by continuity of texture but by the use of an accompanying *basso continuo*. From this type of accompanied madrigal it was a comparatively short step to the cantata, which in the 17th century was to take its place as the most elevated form of secular vocal music.

In France, Germany and Spain, the Italian madrigal made its influence felt on the native forms of secular part song, but nowhere was it so enthusiastically imitated or so completely naturalized as in England. Madrigals had been known at court since the later years of Henry VIII, but it was not until the 1580s that they achieved real popularity. In 1588 Nicholas Yonge was able to publish a large collection of Italian madrigals in English translation under the title *Musica Transalpina*, and similar collections followed it. William Byrd (1543–1623) was already a mature artist and was little influenced in his secular music by the Italian style, but his pupil Thomas Morley embraced it wholeheartedly,

and even had two of his sets published in an Italian version as well as in the original English. Morley excelled in the lighter and more cheerful types of madrigal, such as canzonets ("little short songs" as he calls them) and ballets: the latter he modeled on the *balletti* of Giovanni Giacomo Gastoldi, but achieved a more elaborate musical development and a stronger sense of harmonic direction. John Wilbye (1574–1638) and Thomas Weelkes (c. 1570?–1623) brought to the English madrigal a new depth of feeling and on occasion a profound melancholy that is not characteristic of the Italian school; Wilbye is the purer stylist, but Weelkes the bolder and more individual.

Of the later English madrigal publications those of Orlando Gibbons and Thomas Tomkins, published in 1612 and 1622 respectively, are the best, but although the fashion for madrigals lasted only about 40 years in England it had in that comparatively short space of time produced a remarkable quantity of fine music.

The tradition of madrigal singing was revived in England in the early 18th century. The Madrigal society (founded by John Imyns in 1741, and still in existence) and John C. Pepusch's Academy of Ancient Music kept the practice alive in London, and it also flourished among the lay clerks of cathedral and collegiate churches throughout the country. At the meetings of these groups both English and foreign madrigals were sung, together with later compositions written in imitation of their style. In the 19th century there appeared two studies of the madrigal repertory—T. Oliphant's *La Musa Madrigalesca* (1837) and E. F. Rimbault's *Bibliotheca Madrigaliana* (1847)—and G. E. P. Arkwright provided both historical studies of the composers and editions of their music in a more scientific way at the beginning of the 20th century. It was, however, the work of E. H. Fellowes, above all, that made this repertory available for study and performance; his complete edition of *The English Madrigal School*, 36 vol. (1913–24), is among the monuments of British musicology; and his book *The English Madrigal Composers* (2nd ed., 1948), and his edition of the poetic texts in *English Madrigal Verse* (2nd ed., 1929) form a worthy complement to it. The subject has most recently been surveyed in Joseph Kerman's *The Elizabethan Madrigal: a Comparative Study* (1962).

Studies and editions of the two Italian schools of madrigalists are too scattered and extensive to be listed here, but details of the earlier may be found in any bibliography of the Italian Ars Nova, while an indispensable guide to the later is Alfred Einstein's *The Italian Madrigal*, 3 vol. (1949). Einstein left the vast collection of manuscript scores on which he had based his comprehensive survey to Smith college, Northampton, Mass., where they form a unique library for any student of the subject. A general survey and detailed bibliography may be found in G. Reese, *Music in the Renaissance* (1954, rev. ed., 1959). (J. J. N.)

MADRÍZ, a small department in the northwestern part of the central highlands in Nicaragua. Area 679 sq.mi.; pop. (1963) 50,229, of which 83% was rural. Somoto (pop. [1963] 9,215) is the largest town and departmental capital. Despite its rugged relief, and because of rather fertile valley soils and 60 or more inches of rain per year, the department is significant in the production of swine, cattle, horses, mules, coffee, brown sugar (panela), cotton, vegetables and subtropical fruits. Until the construction of the Inter-American highway across the department, giving it access to Managua, 136 mi. away, Madríz depended chiefly upon pack and air transportation. (C. F. J.)

MADROÑA (*Arbutus menziesii*), a handsome North American broad-leaved evergreen tree of the heath family (Ericaceae), called also madrone, madroño and laurelwood, native to the coast region from British Columbia to southern California. It is a widely branching tree, growing to a height of 125 ft., with a trunk diameter exceeding 4 ft.; polished crimson to dark-brown bark; large, lustrous, dark-green leaves, nearly white beneath; small, heathlike, white flowers in dense clusters; and bright orange-red, berrylike fruit.

MADURA (Dutch MADOERA), an island of Indonesia in East Java province, lying off the northeast coast of Java, opposite Surabaja, from which it is separated by a shallow strait of less than 1½ mi. The island is 100 mi. long and 24 mi. wide and has

an area of 2,113 sq.mi. Pop. (1957 est.) 1,883,401. It has an undulating surface but no mountains, 700 ft. being the greatest elevation in the west and 1,565 ft. in the east. In the north the hills run down nearly to the sea; in the northwest and south there are extensive alluvial plains, while the south coast is fringed with islets, shoals and mudbanks. The geological formation reveals the relation of Madura to northern Java (*q.v.*), since it consists largely of the same limestone rocks, of Tertiary formation, with low alluvial tracts. There are hot springs. Off the eastern coast are several islands—Sapudi and the Kangean group, Kangean Island being 25 mi. long and from 3 to 12 mi. wide, with hills reaching 1,197 ft.

The climate, flora and fauna of Madura resemble those of east Java. Vegetation is luxuriant, but the soil is less fertile than the average soil in Java; as an indication of this, rice has to be imported to meet the needs of the population. Maize and cassava are the main crops, but rice, coconuts, coffee, cacao, kapok and most of the usual Indonesian fruits and vegetables are grown. Kapok, copra and coconut oil figure largely in exports, as does teak from the extensive forests in the northwest. The island is well adapted for cattle breeding, which is engaged in extensively. The wide expanse of coast, well sheltered on the southern side, gives opportunity for fishing. The Kangean Islands and Sapudi yield timber, trepang and tortoiseshell. The principal industry is salt panning, a government monopoly. The salt is obtained from saline springs and from sea water; the largest pans are situated at Kalianget. Manufacture is according to European method and employs many. Petroleum has been found and is worked on a small scale.

The Madurese (Muslims) are keen traders, fishermen and sailors; they are less good as craftsmen. They tend to be shorter but more sturdily built than the Javanese. Amusements are bull racing and bullfighting; the races, usually held in the month of September, attract huge crowds.

The capital of the island is Pamekasan, in the central southern part of the island, not far from the coast (pop. [1957 est.] 23,121). Other towns are Sumenep (pop. [1957 est.] 33,628), near which are the tombs of the princes of Sumenep; Bangkalan (pop. [1957 est.] 29,536), with the old palace of the sultan of Bangkalan, or Madura, and an interesting mosque; Sampang (pop. [1957 est.] 47,596); Kamal; and Kalianget.

A tram line crosses the island from west to east, from Kamal to Kalianget, connection being maintained with Java by means of a ferry service between Surabaya and Kamal; the line extends to Bangkalan, in the north, and passes through Pamekasan and Sumenep. There are roads along the north and south coasts, and across the centre of the island.

Dutch influence was established in Madura late in the 17th century, and the power of the ambitious prince of Madura was circumscribed by the division of the island into three regencies, Madura (or Bangkalan), Pamekasan and Sumenep, each having its own prince, or sultan. After much misrule, the regencies were united in 1885 under a residency attached to Java. In 1949 Madura became part of the Republic of Indonesia. (E. E. L.)

MADURAI, a city and district of Madras, India. The city, headquarters of the district, lies on the Vaigai river, 305 mi. S.W. of Madras. Pop. (1961) 424,810. It is an ancient historic city of south India, and has been a centre of Dravidian culture for more than 2,000 years. The standing monuments of Dravidian architecture are the Tirumala Nayak palace (restored and now used for public offices) and the Great temple comprising the twin temples of Meenakshi (Minakshi, "the fish-eyed goddess" and consort of Shiva) on the south and Shiva or Sundareswar on the north with the Sahasrastambha Mandapam or the hall of a thousand pillars in the northeast corner of the temple complex. The immense precincts of the Great Meenakshi temple are dominated by nine exquisitely carved gopurams, or tower gates, the tallest of which is 152 ft. high. There are seven colleges, all affiliated to the Madras university; the oldest and biggest is the American college founded by the American mission. Other colleges include two for women and Government Medical college. In 1958 Madras university established a regional centre at Madurai with departments of study

and research. The city is an important cotton-manufacturing centre of a rich cotton-producing area, and has nine mills. It is a junction on the Southern railway.

Madurai was the capital of the Pandyan kings from the 5th century B.C. to the end of the 11th century A.D. In 1310 it was plundered by a Muslim army under Malik Kafur. It formed part of the empire of Mohammed ibn Tughlak until 1334 when Sayyid Ahsan, the governor, revolted and established the independent sultanate of Madurai. After 1378 this was absorbed by the Hindu empire of Vijayanagar. In the middle of the 16th century the governor Viswanath established the Nayak dynasty which ruled for a century. The greatest of the Nayaks was Tirumala (reigned 1623–59) who adorned Madurai with many public buildings and extended his empire over the adjoining districts. Later, Muslims again invaded Madurai and compelled Tirumala to pay them tribute. After his death, the kingdom of Madurai gradually fell to pieces, being invaded both by Muslims and Marathas. About 1736 the district fell into the hands of the nawab of Carnatic, and the line of the Nayaks was extinguished. In 1764 British officers took charge of Madurai in trust for the last independent nawab of Carnatic, whose son finally ceded his rights to the East India company in 1801.

MADURAI DISTRICT (area 4,910 sq.mi.; pop. [1961] 3,211,227) has always been important because of its agricultural wealth, the result of the unique system of irrigation which diverts the waters of the river Periyar flowing into the Arabian sea through a tunnel across the Western Ghats into the Vaigai basin, to irrigate 150,000 ac. of land. On the Palni hills stands the famous sanatorium of Kodaikanal (*q.v.*), and on their slopes cardamoms, tea and coffee are cultivated. The Sirumalais (smaller hills) are famous for the exceptionally sweet variety of plantains; vines and grapes are found in a few favoured spots of the Periakulam taluka. There are numerous cotton-spinning, weaving, ginning and pressing mills. However, the production of raw cotton meets with only 15% of the local demand.

Gandhigram, about 40 mi. from Madurai, is the site of a new rural institute with facilities for higher studies in agriculture, engineering, hygiene, etc. Co-operative farming was being attempted in the mid-1960s, and on the success of this depends the future of co-operative farming in south India. Other projects include the Vaigai reservoir project to irrigate another 10,000 ac. and the Periyar power station to generate 105,000 kw. of hydro-electricity. (G. K.N.)

MADURESE LANGUAGE, like most languages of Indonesia, is one of the Malayo-Polynesian languages (*q.v.*). It is most closely related to the languages of western Indonesia such as Javanese and Malay. It is the native language of about 8,000,000 Indonesians and thus shares with Malay third position among the languages of the country. Its speakers are distributed mainly over Madura and nearby islands, the Kangean and Sapudi Islands and the section of the eastern peninsula of Java which faces Madura. There are two main dialects: Western Madurese, which has two subdialects with centres respectively at Pamekasan and Bangkalan, and Eastern Madurese with its centre at Sumenep. Madurese has different status styles: the *allos* (literally "fine") for deferential address, the *kasar* (literally "coarse") for familiar address and the *tengngagaan* (literally "middle") for otherwise undefined address. The difference between the styles is not so great as that of the Javanese and Sundanese styles.

Madurese is traditionally written in an adapted form of the Javanese alphabet. Madurese formerly was rarely used in writings because of the domination by Javanese princes and then by the Netherlands Indies government. The chief original Madurese writings are some historical works, the remainder being mainly translations from the Javanese. (I. D.N.)

MADVIG, JOHAN NICOLAI (1804–1886), Danish philologist, whose chief work was the study and teaching of Latin and Greek and the improvement of the classical schools, was born on the island of Bornholm on Aug. 7, 1804. He was educated at Frederiksborg and at the University of Copenhagen, where in 1829 he became professor of Latin language and literature. In 1840 Madvig entered parliament and became minister of education and

later (1852) director of public instruction. From 1856 to 1863 he was president of the council and leader of the National Liberal party. Madvig died at Copenhagen on Dec. 12, 1886.

Besides his unsurpassed edition of Cicero's *De finibus* (1839; 3rd ed., 1876), Madvig published *Der römische Stats Forfatning og Forvaltning*, 2 vol. (1881–82); *Livseringringer* (1887); and many works on Latin grammar and Greek syntax.

See J. E. Sandys, *History of Classical Scholarship*, 2nd ed., iii (1908).

MAEBASHI, industrial city and communications centre, is the capital of Gumma prefecture, Japan. The city grew rapidly in size and population after World War II. Pop. (1947) 90,432; (1960) 181,937. Maebashi remains a centre of sericulture and silk-yarn production in spite of the general decline of the silk industry. An old castle town, in the Muramachi period it was called Umayabashi and in the Tokugawa period it was the seat of the Matsudaira family.

(C. A. Mr.)

MAECENAS, GAIUS (d. 8 B.C.), Roman statesman and patron of letters, was probably born between 74 and 64 B.C., perhaps at Arretium (Arezzo). He prided himself on his Etruscan lineage and claimed descent from the princely Cilnii of Arretium; Tacitus (*Annals*, vi, 11) actually calls him Cilnius Maecenas, though this does not appear to have been his name. His great wealth may have been in part hereditary, but he owed his position and influence to his close association with the emperor Augustus. He may have taken part in the battle of Philippi (42), but he first appears in history in 40, when he was employed by Octavian (as Augustus at this date is usually known) in arranging his marriage with Scribonia, and afterward in assisting to negotiate the peace of Brundisium and the reconciliation with Mark Antony. It was in 39 that Horace was introduced to Maecenas, who had before this received Varius Rufus and Virgil into his intimacy. In the "Journey to Brundisium" (Horace, *Satires*, i, 5) in 37, Maecenas and L. Cocceius Nerva are described as having been sent on an important mission, and they were successful in patching up, by the treaty of Tarentum, a reconciliation between the two claimants for supreme power. During the Sicilian war against Sextus Pompeius in 36 Maecenas was sent back to Rome and was entrusted with supreme administrative control in the city and in Italy. During the campaign of Actium (31) he was left in charge at Rome again and with great promptness and secrecy crushed the conspiracy of the younger Lepidus. He remained an *eques* and held no public offices, but he was one of the most important men around Augustus; an anonymous elegy composed after his death calls him "Caesar's right hand." In the latter years of his life he fell somewhat out of favour; he died in 8 B.C., leaving the emperor heir to his wealth.

Maecenas impressed ancient writers by the contrast between the great energy and ability he showed in public life and the luxury and hedonism of his relaxations. His character as a munificent patron of literature has made his name a household word. His patronage was exercised with a political object; he sought to use the genius of the poets of the day to glorify the new regime. The diversion of Virgil and Horace toward themes of public interest may be ascribed to him, and he endeavoured less successfully to do the same thing with Propertius. The relationship between Maecenas and his circle is largely a matter of conjecture, but he and Horace were certainly personal friends. It has fallen to the lot of no other patron of literature to have his name associated with works of such lasting importance as the *Georgics* of Virgil, the first three books of Horace's *Odes*, and the first book of his *Epistles*.

Maecenas himself wrote in both prose and verse; only fragments survive. His prose works on various subjects—*Prometheus*, *Symposium* (a banquet at which Virgil, Horace and Messalla Corvinus were present), *De cultu suo* (on his manner of life)—were ridiculed by Augustus, Seneca and Quintilian for their undisciplined style.

BIBLIOGRAPHY.—The fragments are collected in R. Avallone, *Meecenate: I Frammenti* (1945); verse fragments alone in W. Morel, *Fragmenta poetarum Latinorum*, pp. 101 ff. (1927). See also V. Garthausen, *Augustus und seine Zeit*, vol. i, pp. 762 ff., vol. ii, pp. 432 ff. (1891–1904); R. Syme, *The Roman Revolution*, 2nd ed., index (1951).

MAELIUS, SPURIUS (d. 439 B.C.), a wealthy Roman plebeian who during a severe famine bought up a large amount of corn and sold it at a low price to the people. Lucius Minucius, the patrician *praefectus annonae* (president of the market), thereupon accused him of courting popularity with a view to making himself king.

Maelius, summoned before the aged Cincinnatus (specially appointed dictator), refused to appear, and was killed by Gaius Servilius Ahala; his house was razed to the ground and the open space called Aequimaellum, on which it had stood, preserved the memory of his death. Despite later accretions, the basis of the story is probably historical, since it goes back to the annalist L. Cincius Alimentus (late 3rd century B.C.) and is not a fabrication by the annalists writing after the time of Tiberius and Gaius Gracchus, when corn became a political issue.

See Livy, iv, 13.

MAELSTROM, a term originally applied to the Moskenstrom, a strong current running between the islands of Moskenaes and Mosken in the Lofoten Islands off the west coast of Norway. It is crossed by strong tidal currents which change directions frequently. Its power has been much exaggerated though it is dangerous in certain states of wind and tide. The original name occurs on Mercator's *Atlas* of 1595; the term has been used generically for large whirlpools elsewhere and figuratively for any turmoil of wide-reaching influence. It is probably from Dutch *malen*, "to grind," and *stroom*, "a stream."

MAENAD, in Greek mythology one of the female attendants who shared in the nocturnal orgiastic rites of Dionysus (*q.v.*). They also are called Bacchae, Lenae, Thyiades, Clodones and Mimaiones.

MAE NAM CHAO PHRAYA (CHAUPAYA), the most useful river system in Thailand, enters the Gulf of Siam 25 mi. below Bangkok. The Chao Phraya is formed by four large tributaries which flow southward from north Thailand between alternate mountain ranges. These four rivers from west to east are the Ping, Wang, Yom, and Nan. The Ping, the largest tributary, is joined by the Wang near Tak (240 mi. N.N.W. of Bangkok) and the Nan is joined by the Yom near Chumsaeng. The Chao Phraya originates at the junction of the Ping and Nan rivers just north of Nakhornsawan (140 mi. N.N.W. of Bangkok). Because of the low relief of the central plain (which is an old filled arm of the Gulf of Siam), the Chao Phraya has many distributaries. Near Chainat, about 34 mi. below Nakhornsawan, a distributary branching off to the west continues southward and parallel to the Chao Phraya until it enters the gulf. This river is known by several names in different parts of its course, such as Supan and Tha Chin. Another large distributary called the Noi branches off to the west from the main stream below Chainat but rejoins the Chao Phraya at Sam Khok.

About 20 mi. below Chainat an eastern distributary, the Lopburi, branches off and after flowing by the cities of Lopburi and Ayutthaya (Phranakbhorn-ayuthya) rejoins the Chao Phraya at Sam Khok.

From the east the Chao Phraya is joined by its largest tributary in the central plain, the Pa Sak. The Pa Sak flows south parallel to the Dong Phraya Yen range (which separates northeast Thailand from the central plain) to the Lopburi river.

For centuries the Thais have used the Chao Phraya system as a source of domestic, livestock and irrigation water and for transportation, drainage, fishing and recreation. The lower reaches of the rivers in the central plain have been joined with a network of canals that brings rice, teak and other products to Bangkok.

(T. F. B.)

MAERLANT, JACOB VAN (c. 1225–c. 1291), the pioneer of the didactic poetry that flourished in the Netherlands in the 14th century. A Fleming by birth, he was born in Vrije van Brugge (Damme?). The details of his life are disputed, but he was probably sexton at Maerlant near Brielle on Voorne between 1255 and 1265(?) and was employed by Albrecht van Voorne, Nicholas Cats, lord of North Beveland, and Floris V, count of Holland. About 1266 he became clerk to the court at Damme, where he died shortly after 1291. Maerlant reveals careful edu-

cation by his intimate knowledge of both Latin and French. His early works were versions of medieval romances—*Alexanders Geesten*, based on Gautier de Châtillon's Latin *Alexandreis*; *Historie van den Grale Merlijn* (c. 1260), freely translated from Robert de Borron's early contributions to the Arthurian cycle; *Torec* (c. 1262); and, most important, the *Historie van Troyen* (c. 1264), from the *Roman de Troie* ascribed to Benoît de Sainte Maure. These chivalric epic romances belong to the period of Maerlant's contact with the world of nobility, but it is interesting that even in them he shows a tendency to treat his subjects historically and to correct and amplify his sources by reference to Latin texts.

When Maerlant began to write with the definite aim of providing instruction, he turned entirely to Latin sources, writing a scientific compilation, *Der Naturen Bloeme* (1266–69?), after Thomas of Cantimpré's *De natura rerum*; a life of St. Francis (before 1273), based on Bonaventura; the *Rijmbijbel* (1271), after Petrus Comestor's *Historia Scolastica*; and, finally, his most important work, *Spiegel Historiae*, an adaptation with additions of his own of Vincent de Beauvais's *Speculum Historiale*, begun c. 1282 and completed after his death by Philippe Utenbroeke and Lodewijk van Velthem.

These moralizing rhymed encyclopaedic works were written to satisfy the rising class of commoners who wished for instructive reading in their own language. Among Maerlant's many followers in this kind the most notable were Jan van Boendale, Lodewijk van Velthem and Jan de Weert. His own considerable gifts as a religious poet are also more fully shown in his strophic poems—especially *Wapene Martijn*, a dialogue poem in which he discusses the decadence of the period and treats moral problems with great earnestness—and in his fervent *Disputacie van Onser Vrouwen ende vanden Heilighen Cruce* and *Van den Lande van Oversee* which scourges the laxity of the church and calls for a new crusade.

MAES (MAAS), NICOLAES (NICOLAS) (1632–1693), Dutch painter, a follower of Rembrandt, was born at Dordrecht. About 1650 he went to Amsterdam, where he entered Rembrandt's studio. Before his return to Dordrecht in 1654 Maes painted a few Rembrandtesque genre pictures, with life-size figures and in a deep glowing scheme of colour, as in the "Reverie" at the Ryks museum in Amsterdam, the "Card Players" at the National gallery, London, and the "Children With a Goat Carriage," in the J. P. Morgan collection, New York city. In his best period, from 1655 to 1665, Maes devoted himself to domestic genre on a smaller scale, retaining to a great extent the magic of colour he had learned from Rembrandt.

His favourite subjects were women spinning, or reading the Bible, or preparing a meal. He visited Antwerp between 1660 and 1670, and his Antwerp period coincides with a complete change in style and subject. He devoted himself almost exclusively to portraiture, and abandoned the intimacy and glowing colour harmonies of his earlier work for a careless elegance which suggests the influence of Van Dyck. The change gave rise to the theory of the existence of another Maes, of Brussels. Maes is well represented at the National gallery by five paintings: "The Cradle," "The Dutch Housewife," "The Idle Servant," "The Card Players" and a man's portrait. At Amsterdam, besides the splendid examples to be found at the Ryks museum, is the "Inquisitive Servant" of the Six collection. At Buckingham palace is "The Idle Servant," and at Apsley house "Selling Milk" and "The Listener." There are examples in New York, Boston, Philadelphia, San Francisco and other American cities.

MAESTRO: see WIND: *Local Winds*.

MAETERLINCK, MAURICE POLYDORÉ MARIE BERNARD (1862–1949), Belgian dramatist, critic and poet who created the Symbolist theatre; he received the Nobel prize for literature in 1911. Born at Ghent, on Aug. 29, 1862, he was educated at the Jesuit Collège de Sainte Barbe, and studied law at the University of Ghent. In Paris, 1885–86, he met Villiers de L'Isle-

Adam (q.v.) and the leaders of the Symbolist movement (see SYMBOLISTS, THE). In 1886 he returned to Ghent, where he lived until 1889. His first volume of verse, *Serres Chaudes*, and his first play, *La Princesse Maleine*, appeared in 1889 (Eng. trans. 1915); the play was originally composed in metre, but rewritten in prose. In 1890 he published two more plays, *L'Intruse* and *Les Aveugles*, followed by *Les Sept Princesses* (publ. 1891). His leaning toward mysticism was defined or explained by a translation of *Die Zierde der Geistlichen Hochzeit* by the Dutch mystic Jan van Ruysbroeck (q.v.), as *L'Ornement des noces spirituelles* (1891). In 1892 came *Pelléas et Mélisande* (Eng. trans. 1894), set to music by Debussy, followed in 1894 by the "little plays for marionettes," *Alladines et Palomides*, *Intérieur* (Eng. trans. 1898) and *La Mort de Tintagiles*.

In 1895 Maeterlinck translated, as *Annabella*, John Ford's *The Pity She's a Whore*. Two philosophical works followed, a study of Novalis (1895) and *Le Trésor des humbles* (1896; Eng. trans. 1897). In 1896 he returned to drama with *Aglavaine et Sélysette* and to lyric verse with *Douze Chansons*, to which three poems were later added. A monograph on the ethics of mysticism, *La Sagesse et la Destinée*, a kind of commentary on his own dramas, came out in 1898; and a volume of prose, *La Vie des abeilles*, which combined philosophy, fancy and natural history, in 1901 (Eng. trans. 1901). He found this form congenial, and *La Vie des termites* (1926; Eng. trans. 1927), *La Vie des fourmis* (1930; Eng. trans. 1930) and *L'Araignée de verre* (1932) are on similar lines, though they show an increasingly pessimistic view of nature.

Maeterlinck wrote several volumes of essays, among them *Le Temple enseveli* (1901; Eng. trans. 1902), *Le Double Jardin* (1904), *L'Intelligence des fleurs* (1907), which has an essay on *King Lear*, and *La Mort* (1913; Eng. trans. 1911). The plays *Monna Vanna* (1902) and *Marie Magdeleine* (1913; produced in Germany, 1910) are of importance. A translation of *Macbeth* appeared in 1910. This period suggests a development from mysticism. His most popular plays were *L'Oiseau bleu* (1908; Eng. trans. *The Blue Bird*, 1909), *Les Fiancailles* (1922) and a war play, *Le Bourgmestre de Stillemonde* (1919). *Le Miracle de Saint-Antoine* (publ. 1919, produced 1903) and *Les Sentiers dans la montagne* (1919) have charm. *Le Malheur passé* (1925) and *La Puissance des morts* (1926) deal with the recurrent themes of man's destiny in love, his relation to past and future, and the nature of death.

It is necessary first to attempt to see Maeterlinck in terms of his tradition and personality. He is indebted to many predecessors—Shakespeare, Jakob Böhme, Swedenborg, Carlyle, Edgar Allan Poe, Rossetti, William Morris, Puvis de Chavannes. Sir James Barrie. His early work was done under Symbolist influence, and the significance of some of his symbols remains controversial. His art is in some degree conditioned by his search for essences, for a drama that attempts communication by formal qualities stripped of what the dramatist regards as inessential. Even words are mistrusted as apt to obscure "the communion of soul with soul."

Maeterlinck's beliefs are to be found in part in the essay "Le Tragique Quotidien" in *Le Trésor des humbles*. Tragedy is a matter of everyday experience. Its statement in the theatre is a mystery, "the expression of those profound emotions that exist in solitude and silence." He is much possessed by death, its immanence in human life and man's fear of it. This theme, together with the exaltation of spiritual love, finds expression in many plays. The soul is the vital essence, capable of communicating and achieving unity with a "wisdom and spirit of the universe." There is a body of collective and intuitive wisdom, chiefly apparent in women and children and in "humble and rustic characters." Here Maeterlinck shows affinities with Wordsworth, and perhaps links with Freud's (and Jung's) "collective unconscious" and the "Great Memory" of W. B. Yeats.

Maeterlinck admired Aeschylus, and found in him examples of a "static theatre." Yet he relies not only on poetic speech, but on the active significance of symbols. These were, in theory, unconscious creations, rather than intellectual correspondences. In practice the symbolism is simple and usually traditional; light, darkness, doors, windows, sight and blindness, lamplight, grottoes,

fountains are used to produce an atmosphere intense rather than complex. Often the protagonists are waiting for something mysterious and fearful that will destroy them. The Invisible Presence is Death, and fate encircles the characters. This profound and moving atmosphere is subserved by a dialogue that is tentative, using half-formed suggestions, at times naively repetitious, occasionally sentimental, but sometimes of great subtlety and power.

Maeterlinck's theatre, and the concept of static drama, which he abandoned for a more active structure, achieved its greatest popularity in the early 20th century. *The Blue Bird*, an allegorical fantasy in the Barrie manner, had great success, particularly in the United States; in it Maeterlinck showed understanding of the child's fairy world, and a qualified optimism that diminished with age. It is not unfair to suggest that his lasting importance is mainly in relation to the history of dramatic theory. His characters have life, but it is a peculiar and remote life. The delicacy of shading and of atmosphere demand an audience smaller and more sympathetic than is usual; the symbols are tenuous and fragile. It is possible that his psychological theory, verging on a mystical attitude at times sentimental or whimsical, is out of sympathy with the modern age.

Maeterlinck twice visited the United States, where he lived from 1940 to 1947, writing *Jeanne d'Arc* (1940), *Les Trois Justiciers* (1942) (both publ. 1959), *Le Jugement dernier* (1944) and the unpublished *Le Miracle des mères*. In 1947 he returned to Orlamonde, near Nice, his home from 1930 to the fall of France, and he died on May 6, 1949, in a hotel at Nice. He had been created count in 1932.

There are many editions in several languages; among the main English translations are those by A. Sutro, A. Texeira de Mattos and B. Niall.

(T. R. Hn.)

MAEZTU Y WHITNEY, RAMIRO DE (1874–1936), Spanish political writer, a brilliant and belligerent journalist and a member of the so-called "generation of '98," was born in Vitoria on May 4, 1874. Maeztu's thought evolved from a nihilism deriving from Nietzsche to a rigid traditionalism, a strong nationalistic urge—despite his English mother and wife—dominated throughout his life. From 1905 to 1916 he worked in London as correspondent for Spanish newspapers, in close contact with radical socialism (*q.v.*). On returning to Spain, he supported the dictatorship of Primo de Rivera. Later he was a vehement opponent of the republic and wrote the standard work of traditionalism, *La defensa de la Hispanidad* (1934). His other works include *Hacia otra España* (1899), *Authority, Liberty and Function in the Light of the War* (1916), and *Don Quijote, Don Juan y la Celestina* (1926). Maeztu was shot by the Republicans at Aravaca, Madrid, probably on Oct. 29, 1936, in the early days of the Spanish civil war.

See Vicente Suárez Marrero, *Maestu* (1955). (G. W. Rs.)

MAFEKING, a town in the northeast corner of Cape province, S.Af., close to the Bechuanaland border. It lies at 4,194 ft. altitude, 853 mi. N.E. of Cape Town by road (871 mi. by rail). Pop. (1960) 8,279; white, 4,159. Until early 1965 Mafeking was the administrative headquarters of the British protectorate of Bechuanaland. It is also the headquarters of the railway system between Kimberley and Bulawayo, Southern Rhodesia. Native Stad on the Molopo river 1 mi. distant is the chief place of the Barolong tribe. Founded in 1885, Mafeking was in the South African War besieged by the Boers from Oct. 12, 1899, to May 17, 1900. The Anglican church and a memorial in front of the town hall were erected in memory of those who died in the defense. The surrounding country supports important cattle farming and dairy industries. See also SOUTH AFRICAN WAR.

MAFFEI, FRANCESCO SCIPIONE, MARCHESE DI 1675–1755, Italian dramatist and scholar, who in his verse tragedy *Merope* (1713) attempted to introduce French classical

simplicity into Italian drama, was born at Verona, June 1, 1675. After studying at Parma, he fought in the War of the Spanish Succession. Becoming interested in the archaeology of his native town, he wrote a valuable account of its history and antiquities, *Verona illustrata* (1731–32). He died in Verona, Feb. 11, 1755.

Besides *Merope*, his works include *Teatro italiano*, a collection of 12 plays (1723), translations of the *Iliad* and the *Aeneid*, and many scholarly studies. A modern edition of Maffei's works by A. Avena appeared in 1928.

See G. Gasperoni, *Scipione Maffei e Verona Settecentesca* (1955).

MAFIA (MAFFIA). A word of uncertain origin, anglicized as mafia, used to designate a specific form of criminality which arose on the great landed estates (*latifundia*) of Sicily as a result of bad government during a long period of the island's history, and more especially during the disorders consequent on the Napoleonic invasion of south Italy. Lawless conditions led the owners of large estates to place their lands in the charge of energetic ruffians who exercised almost despotic powers over a terrorized peasantry. The contiguity of the estates enabled these men to form an organization which gradually became very extensive and powerful, so much so that in time it turned against the landowners themselves. The members of the organization were not very numerous, but, bound by close ties of fellowship and capable of any crime, they compelled the landowners to employ persons of their choice, fixed the compensation they claimed for their services, and the rents and price of the lands and of the crops entrusted to their protection. Their activities sometimes extended to neighbouring towns; they made it practically impossible for lands or crops to be sold at open auction, and effectively hindered efforts likely to interfere with their interests.

On the other hand, fierce quarrels of all kinds arose among them leading to terrible acts of revenge, whence the formation of bands of outlaws, at feud among themselves, and all the crimes consequent on outlawry.

A complicated code of traditions regulated the Mafia, based on so-called *omertà* (from Sicilian *omu*, man), the obligation never, under any circumstances, to apply for justice to the legally constituted authorities, and never to assist in any way in the detection of crime committed against oneself or others. Absolute silence was required and enforced by ruthless reprisals, the right to avenge injuries being reserved to the victims or their families. Like the Camorra (*q.v.*), the Mafia was soon powerful in various social classes.

After the fall of the local Bourbon monarchy in 1860, the Italian government endeavoured with varying success to rid Sicily of the Mafia; but in the various Sicilian provinces the police authorities continued to tolerate it. When the fascist regime came into power, after 1922, it used its exceptional powers to capture and bring to trial the leaders of the Mafia. In a series of trials at Palermo and neighbouring Termini Imerese, in 1927, the accused, in batches of as many as 150, were brought before the courts; and their victims gave evidence against them. The leaders received life sentences and heavy punishment was meted out to their accomplices. Unfortunately, the fascist government used this occasion to get rid, at the same time, of honest Sicilians strongly opposed to it. And this fact became an advantage for the legend of the Mafia which, although composed of criminals, did not lack in its distant origins a certain chivalrous element, since it had once appeared to many as a force fighting Spanish misrule and feudal abuses.

In spite of all repressive efforts the Mafia persisted. Following World War II the land reforms weakened its power in the rural areas of central and western Sicily. Its strongholds, and its extortionary and other activities were then directed more to industrial, business and construction enterprises.

Organized crime in the United States, some observers have pointed out, bears many resemblances to the Mafia in its philosophy, methods of operation and local organization. In 1950–51, the U.S. senate special crime investigating committee reported that U.S. gangster syndicates had close business relations with the Mafia. Similar allegations were made in 1958 by witnesses before the U.S. senate select committee on improper activities in the labour management field.

Mori, *The Last Struggle with the Mafia* (1933). Frederic Sondern, Jr., *Brotherhood of Evil: the Mafia* (1959). (O. R. A.; T. Sw.)

MAFRA, a town of Portugal in Lisboa district, 32 km. (20 mi.) N.W. of Lisbon by rail and road. Pop. (1960) 7,032. Mafra is remarkable for its monastery, church and palace, built by John V in 1717–32 in fulfillment of a vow. The building is in the form of a parallelogram measuring more than 800 ft. from north to south and 700 ft. from east to west; it is said to contain 866 rooms. Some of the sculptures are by Machado de Castro, others are by Italian artists or were imported from Italy. The beautiful library is one of the richest of its kind in Europe. The church is sumptuously built of a great variety of marbles and richly adorned with statues, low reliefs and other objects of art. In each of the twin towers is a carillon of 57 bells.

MAGADAN, a port and oblast centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the northern coast of the Sea of Okhotsk, at the head of the narrow Nagayeva bay of Tauskaya gulf. Pop. (1959) 62,225. It was founded in 1933 near the fishing village of Nagayevo, which it later absorbed, and its sheltered position provides the best harbour on the Sea of Okhotsk. A highway leads over the mountains behind the town to the Kolyma gold fields. There is a fish cannery.

MAGADAN OBLAST was formed in 1953 out of Khabarovsk *krai*. Its huge area of 462,973 sq.mi. extends from the Sea of Okhotsk to the Arctic ocean and the Bering strait and includes the Chukot National Okrug (*q.v.*). Most of the area is highly mountainous. The main rivers are the upper Kolyma, Omolon and Anadyr. The south is in taiga forest of larch, spruce, pine, fir and birch, and the north and northeast in tundra of mosses and lichens. The population is only 235,578, of which 82% is urban. The majority are Russians, but the 42,357 rural dwellers are mostly indigenous peoples, Chukchi, Eveny, Evenki and Yakuts, who are engaged in reindeer herding, fishing and hunting. The only important occupation is mining, for gold in the upper Kolyma valley and for tin at Seimchan and Yagodnoye. Some timber is cut, and there is a little fishing along the Okhotsk coast. A mere 17 sq.mi. are cropped, chiefly with vegetables. (R. A. F.)

MAGADHA, an ancient kingdom of India, comprising originally the Patna and Gaya districts of modern Bihar. It was the nucleus of several larger kingdoms or empires between the 6th century B.C. and the 8th century A.D. Under King Bimbisara (c. 550–490 B.C.) of the Haryanka line the kingdom of Anga (east Bihar) was added to Magadha. Kosala was annexed later. The Nanda kings continued the supremacy of Magadha in the 4th century B.C. It retained this position during the Mauryan period (4th to 2nd centuries B.C.) when the empire included almost the entire subcontinent of India. The early centuries A.D. saw the decline of Magadha, but the rise of the imperial Guptas in the 4th century A.D. brought it once more to a position of preeminence. Not only did these imperial dynasties begin by establishing their power in Magadha but in each case Pataliputra (adjacent to modern Patna) was the imperial capital, thus adding to the prestige of Magadha. Lively accounts of Pataliputra and Magadha are available in the *Indica* of Megasthenes (fl. c. 300 B.C.) and in the travel diaries of the Chinese Buddhist pilgrims Fa-hsien and Hsuan Tsang (4th–5th and 7th centuries A.D.). The early importance of Magadha may be explained by its strategic position in the Ganges valley which enabled it to control communication and trade on the river. The river further provided a link between Magadha and the rich ports in the Ganges delta. Numerous places in Magadha, the scene of many incidents in Gautama Buddha's life, were sacred to Buddhism, and its early rulers were either Buddhists themselves or played a significant part in the spread and development of Buddhism.

See INDIA-PAKISTAN, SUBCONTINENT OF: *History*.

(R. Th.)

MAGALLANES (Spanish form of Magellan), the southernmost province of Chile, extending from 48° 40' S. to Cape Horn and including the mainland west of the Argentine frontier, the numerous islands fronting the Pacific, the Fuegian archipelago and

the western half of Tierra del Fuego (*q.v.*). Pop. (1960) 79,007. Area 45,081 sq.mi. The area to the west of the Andes is one of the most inhospitable regions of the world, with cool rainy conditions prevailing throughout the year. Many of the islands are barren and where forests occur the terrain prevents their commercial exploitation. The channels, fjords, mountains and glaciers make it a region of great scenic beauty. The area east of the Andes both on the mainland and on Tierra del Fuego, consists of extensive glacial plains covered with tussock grass. Rainfall on these plains nowhere exceeds 40 in. annually.

For three centuries after its discovery by Magellan in 1520 the region was inhabited only by nomadic tribes, of which the chief survivors are the Alacaluf (*q.v.*) in the western channels. In 1811 the settlement of Fuerte Bulnes on the Strait of Magellan established Chile's claim to the area. Six years later Punta Arenas was founded as a penal settlement. The discovery of gold and of the region's pastoral possibilities in the 1880s speeded the occupation of the province. The principal settlements are Punta Arenas (*q.v.*), the provincial capital and chief distributing and administrative centre on the Strait of Magellan, Puerto Natales, serving Última Esperanza, and Porvenir, the port of Tierra del Fuego.

There are large *estancias* in the region east of the Andes where an estimated 2,500,000 sheep produce 80% of Chile's wool. Some frozen mutton is exported from four freezing plants to the United Kingdom but central Chile is the major market. The discovery of petroleum in northern Tierra del Fuego at Manantiales widened the economy of the province. (G. J. B.)

MAGAZINE: see PERIODICAL; LITTLE MAGAZINE.

MAGDALENA, a department in Colombia, lies on the northern coast between the Magdalena river on the west and the Sierra de Perijá and the Guajira peninsula on the east. Area 18,071 sq.mi. Pop. (1961 est.) 500,640. Much of the terrain is swampy flood plain or high mountains including the Sierra Nevada de Santa Marta. The department is the oldest government jurisdiction in Colombia; its capital city, Santa Marta (*q.v.*; pop. [1961 est. 146,650], was founded in 1525. In the second half of the 20th century the excellent natural harbour at Santa Marta experienced a boom at the construction of the Atlantic railway neared completion. The new railroad was planned to link Santa Marta with Bogotá via the Magdalena valley. It would connect with existing railroads at other major inland industrial centres. In the early 1960s the department had more than 150 small industrial enterprises, but the major economic activity is banana raising in the vicinity of Santa Marta. Very poor transportation facilities within the department limit development outside the Santa Marta area. (R. L. G.)

MAGDALENA RIVER rises at the bifurcation of the central and eastern ranges of the Colombian Andes and flows east for 956 mi. to the Caribbean. The major tributaries of the river are the San Jorge, the César and the Cauca (*q.v.*), all of which enter at the northern lowlands and make that area a flood plain with many swamps. The mouth of the Magdalena must be dredged to enable ocean-going vessels to have access to the port of Barranquilla (*q.v.*) near its mouth. Other major river towns from south to north are Neiva, Girardot and Honda. The smaller towns of Puerto Berrio, Puerto Wilches and Barrancabermeja serve adjacent highland areas. The river is navigable by shallow-draft steamboats between Neiva and the sea, interrupted only by rapids at Honda. The course of the river is quite straight. The current is fast and the depth is subject to sharp variations. November is the month in which steamboat traffic is most likely to be interrupted.

The Magdalena has been a major commercial artery since the Spanish conquest. From colonial times to mid-19th century goods were carried in keelboats manned by rivermen (*bogas*) who were as tough and dissolute as those of the Mississippi. Steamships, first introduced in 1822, were profitably operated only after 1850 when the tobacco boom provided sufficient bulk cargo. The riverboat in the 20th century was subject to competition by air, rail and highway, and the end of major steamboat cargo service was probable upon completion of the Atlantic railway. See COLOMBIA: *Physical Geography*. (R. L. G.)

MAGDALENIAN, in archaeology, the term given the last major cultural tradition of the Upper (Late) Paleolithic stage, named after a site at La Madeleine, in the lower Vézère valley, France. In England it is found at Cheddar and Kent's Cavern. See **ARCHAEOLOGY: Culture History of the Pleistocene**.

MAGDEBURG, a city of Germany which after partition of Germany following World War II was located in the *Bezirk* (district) of the same name, German Democratic Republic. It lies on the left bank of the Elbe, 88 mi. S.W. of Berlin, 177 ft. above sea level. Pop. (1961 est.) 262,437.

Magdeburg, which at the beginning of the 9th century was a trading settlement on the frontier of Slavonic lands, owes its importance to Otto I who established the Benedictine monastery of Bergen there about 937. In 962 it became the seat of an archbishop, but the boundaries of the new archbishopric were not set for six years later. It comprised the bishoprics of Havelberg, Merseburg, Meissen and Zeitz-Naumburg. The archbishopric played a great part in the germanization of Slavonic lands east of the Elbe-Saale line.

Although burned down in 1188, Magdeburg became a flourishing commercial town during the 13th century, and was an important member of the Hanseatic league. It became celebrated for establishing in the 13th century an autonomous municipal administration, a model of which, known as the "Magdeburg law" (*Magdeburger Recht*), was later widely adopted not only in Germany but also in many countries of eastern Europe.

From the 13th century the citizens were almost constantly at variance with the archbishops, and by the end of the 15th century became nearly independent of them but failed to achieve the status of a *Reichsstadt*. Under Archbishop Albrecht, a member of the house of Hohenzollern, Magdeburg embraced the Reformation in 1524 and was thenceforth governed by Protestant titular archbishops. During the Thirty Years' War Magdeburg successfully defied Wallenstein for seven months in 1629, but was taken by Tilly on May 20, 1631. The city was sacked and almost entirely burned, and the great part of its 40,000 inhabitants were murdered. By the peace of Westphalia (1648) the archbishopric was converted into a secular duchy, to fall to the Hohenzollern electorate of Brandenburg on the death of the last administrator (August of the Saxon house of Wettin), which happened in 1680. On Nov. 11, 1806, the fortress of Magdeburg surrendered to Napoleon without fighting and until 1813 was part of the kingdom of Westphalia. Magdeburg became the capital of the former Prussian province of Saxony which was constituted in 1816. The city, established in the 17th century on an island in the Elbe between the old town and Friedrichstadt on the right bank of the river, was dismantled in 1912.

The most important building in Magdeburg is the cathedral, dedicated to St. Maurice and St. Catherine. This structure, with its 14-ft.-high towers, begun in the 13th and completed in the 14th century, exhibits an interesting blending of Romanesque and Gothic architecture. The Liebfrauenkirche, the oldest church in Magdeburg, is a Romanesque edifice of the 11th century, completed in the 13th century and restored in 1890-91. The Renaissance town hall (*Rathaus*) was built in 1691 and enlarged in 1866. In front of the town hall stood an equestrian statue of Otto I, destroyed about 1290. With the exception of the *Breite Weg* and the *San Guericke* street running from north to south, the streets of the old town are narrow and crooked. Kloster Berge garden, to the south of the city, is situated on the site of the convent of which was founded in 968 and suppressed in 1809.

At the end of World War II Magdeburg suffered heavily from bombing. Especially devastating was the R.A.F. attack on the night of April 15-16, 1945, followed by a daylight bombing by the U.S.A.F. On that day 65% of the city was destroyed. Captured on April 18, 1945, by the U.S. army, Magdeburg was later divided and included in the Soviet zone. With the exception of a few industries little reconstruction was undertaken.

Before World War II an important industrial center with ironworks producing armour and varied machinery. Of its importance were a synthetic oil plant, chemical factories, paper mills and sugar refineries. By the 1960s these and other

industries were working again at capacity level.

Six railway lines join in Magdeburg linking the city with Berlin, Dessau, Leipzig, Halberstadt, Helmstedt (Brunswick) and Stendal. Seven arterial highways radiate from the city. The Autobahn Berlin-Ruhr crosses the Elbe north of Magdeburg. The city is also a river port, the importance of which greatly increased when the Mittelland canal, linking the Rhine with the Elbe (slightly northward from Magdeburg), was inaugurated on Oct. 30, 1938. Another system of canals links Magdeburg with Berlin and the lower Oder. This makes Magdeburg the most important inland port of the German Democratic Republic.

MAGEE, WILLIAM (1766-1831), Protestant archbishop of Dublin, a controversial preacher who raised the standards of the Church of Ireland, was born on March 18, 1766, at Enniskillen, County Fermanagh, and educated at Trinity college, Dublin, where he was elected fellow in 1788. He was ordained in 1790. His *Discourses on the Scriptural Doctrines of Atonement and Sacrifice* (1801), a polemic against Unitarian theology, was answered by Lant Carpenter. Magee was appointed professor of mathematics and senior fellow of Trinity in 1800, but in 1812 he resigned and in 1813 became dean of Cork. In 1819 he became bishop of Raphoe and in 1822 archbishop of Dublin. Though generally tolerant, he opposed the movement for Catholic emancipation. He died on Aug. 18, 1831, at Stillorgan, near Dublin. His grandson was William Connor Magee (q.v.).

MAGEE, WILLIAM CONNOR (1821-1891), archbishop of York and one of the most brilliant controversialists of his day, was born on Dec. 17, 1821, at Cork and educated at Trinity college, Dublin. He was the grandson of William Magee (q.v.), archbishop of Dublin. In 1864 he became dean of Cork. His remarkable powers were shown in the defense of the Irish church at the time of the disestablishment proposals of 1868, when his brilliant speeches induced Disraeli to offer him the bishopric of Peterborough. He justified this appointment by his magnificent speech when the Disestablishment bill reached the house of lords in 1869. He took up the temperance question, and declared in the house of lords, "It would be better that England should be free than that England should be compulsorily sober," an utterance which the extreme advocates of total abstinence misquoted and attacked. Magee took a prominent part in the ritualist controversy, opposing what he conceived to be romanizing excess in ritual, as well as the endeavour of the opposite party to "put down ritualism," as Disraeli expressed it, by the operation of the civil law. He died in London on May 5, 1891, about four months after his appointment to the see of York.

See J. C. MacDonnell, *Life and Correspondence of William Connor Magee*, 2 vol. (1896).

MAGELANG, the name of a *habupaten* (regency) in the province of Djawa Tengah (central Java), Indonesia, and of its capital. Magelang town, 25 mi. N.N.W. of Jogjakarta, is built on a bend of the Kah Praga, which drains into the Indian ocean south of Jogjakarta. Pop. (1961) 96,454 (municipality). Much damaged during the revolution, it is once again a tourist centre for persons visiting the Borobudur temple. The town has a large Roman Catholic seminary and a military academy. Fine views are to be had of Gunung Sumbing, an active volcano, in a crater of which is a sacred grave of archaeological interest.

The famous Buddhist temple of Borobudur in the form of a pyramid rising more than 30 m. above the base is about 8 mi. S. of Magelang. Built in the 7th or 8th century, it consists of a series of galleries joined by stairways, all leading to the platform at the top. The four lower terraces are square, the three upper circular with 72 bell-shaped shrines, in each of which is a figure of the Buddha. The terraces are richly decorated with statues and bas-reliefs. (See also **INDIAN ARCHITECTURE: Indonesia; JAVA: Archaeology**.) Other nearby places of interest are the smaller temples of Pawon and Mendut, dating from the same period.

MAGELANG KABUPATEN is a region of fertile land and one of the most densely populated parts of Java. Area 436 sq. mi.; pop. (1961) 719,903. Besides the rice, tobacco and sugar grown there flourishing market gardens in the district supply the city of Jogjakarta.

MAGELLAN, FERDINAND (Portuguese FERNÃO DE MAGALHÃES; Spanish HERNANDO DE MAGALLANES) (1480–1521), often referred to as the first circumnavigator of the earth, is more correctly described as initiator and leader of the Magellan-Elcano expedition, since he died before the completion of the first voyage round the world, successfully terminated by the Basque navigator Juan Sebastián de Elcano (del Cano). Son of Rui de Magalhães and Alda de Mesquita, Magellan belonged to the fourth order of Portuguese nobility; his birthplace was most probably Oporto, which he left to serve as a page to Queen Leonor in Lisbon.

Indian Service.—In early 1505 he enlisted in the fleet of Francisco de Almeida, first Portuguese viceroy in the east, whose expedition, sent by King Manuel to check Muslim sea power in Africa and India, left Lisbon on March 25; at a naval engagement at Cannanore on the Malabar coast of India Magellan is said by the chronicler Gaspar Correia to have been wounded. Though Correia states that during this early period of his Indian service he acquired considerable knowledge of navigation, little is known of Magellan's first years in the east until he appears among those sailing in Nov. 1506 with Nuno Vaz Pereira to Sofala on the Mozambique coast, where the Portuguese established a fort. In 1508 he was back in India, taking part in the great battle of Diu, on Feb. 2–3, 1509, which gave the Portuguese supremacy over most of the Indian ocean. Reaching Cochín in the fleet of Diogo Lopes de Sequeira, he left as one of the men-at-arms for Malacca. Magellan is mentioned as being sent to warn the commander of impending attack by Malays, and during the subsequent fighting, courageously saved the life of Francisco Serrão, who later from the Moluccas sent him helpful information about those islands. At a council held at Cochín on Oct. 10, to decide on plans for recapturing Goa, he advised against taking large ships at that season, but the new viceroy, Afonso de Albuquerque, did so, the city falling on Nov. 24; Magellan's name does not appear among those who fought. There is no conclusive evidence that during his Indian service he attained the rank of captain.

The Portuguese victories off the eastern coast of Africa and the western one off India had broken Muslim power in the Indian ocean, and the purpose of Almeida's expedition—to wrest from the Arabs the key points of sea trade—was almost accomplished; but without control of Malacca their achievement was incomplete. At the end of June 1511, therefore, a fleet under Albuquerque left for Malacca, which fell after six weeks. This event, in which Magellan took part, was the crowning Portuguese victory in the orient. Through Malacca passed the wealth of the east to the harbours of the west, and in their command of the Malacca strait the Portuguese held the key to the seas and ports of Malaysia. It remained to explore the wealth-giving Moluccas, the islands of spice. Accordingly, early in Dec. 1511 they sailed on a voyage of reconnaissance, and after reaching Banda returned with spice in 1512. The claim made by some writers that Magellan went on this voyage rests on unproved statements by G. B. Ramusio and Leonardo y Argensola, and the want of evidence is against its acceptance. Even did he, in truth, reach the Moluccas, a further voyage—which he later commanded from Spain to the Philippines—was required to complete the circle of navigation.

In 1512 Magellan was back in Lisbon; the following year he joined the forces sent against the Moroccan stronghold of Azamor, and in a skirmish after its fall received a wound which caused him to limp for the rest of his life. Returning to Lisbon in Nov. 1514 he asked King Manuel for a token increase in his pension, signifying a rise in rank. (He was then *fidalgos escudeiro*; his coat of arms was that of Magalhães e Sousa [Arronches].) Reports (unfounded) of irregular conduct on his part after Azamor had reached the king, who, refusing his request, ordered him back to Morocco. Early in 1516 Magellan renewed his petition; the king, refusing once more, told him he might offer his services elsewhere.

Westward-Sailing Expedition to the East.—Magellan therefore went to Spain, reaching Seville on Oct. 20, 1517, whence, joined by the Portuguese cosmographer Rui Faleiro, he journeyed to court at Valladolid. There, having renounced their nationality, the two men offered their services to King Charles I (later, Emperor Charles V).

By decree of a papal bull, 1493, all new territories discovered or which should be discovered east of a line of demarcation (re-drawn 1494) were assigned to Portugal; all that lay west to Spain. Magellan and Faleiro now proposed by sailing west to give practical proof of their claim that by true facts of longitude the wealth-giving Spice Islands lay within the Spanish, not the Portuguese, hemisphere. On March 22, 1518, their proposal received royal assent; they were appointed joint captains general of an expedition directed to seek an all-Spanish route to the Moluccas. The government of any lands discovered was to be vested in them and their heirs, and they were to receive a one-twentieth share of the net profits from the venture; both were invested with the Order of Santiago. Magellan was convinced that he would lead his ships from the Atlantic to the "Sea of the South" by discovering a strait through Tierra Firme. This idea did not originate with him; others had sought a passage by which vessels sailing continuously westward would reach the east, and thus avoid the Cape route, monopoly of the Portuguese; in the royal agreement Magellan and Faleiro were directed to find "the" strait. India house was instructed to furnish five ships for the expedition, prepared in Seville, where an unsuccessful attempt to wreck the project was made by Portuguese agents. Magellan's flagship, "Trinidad," had as consorts "San Antonio" (captain, Juan de Cartagena), "Concepción" (Gaspar de Quesada), "Victoria" (Luis de Mendoza), "Santiago" (João Serrão). Because of his unbalanced condition Faleiro did not sail.

Magellan, who in 1517 had married Beatriz Barbosa, daughter of an important official in Seville, said farewell to his wife and infant son Rodrigo before his ship left Sanlúcar de Barrameda on Sept. 20, 1519, bearing 265 men, among whom nine countries were represented; the only Englishman was the master gunner, Andrews, of Bristol. The fleet reached Tenerife on Sept. 26, sailing on Oct. 3 for Brazil; becalmed off the Guinea coast, it met storms before reaching the line; on Nov. 29 it was 27 leagues S.W. of Cape St. Augustine. Rounding Cabo Frio, Magellan entered the Bay of Rio de Janeiro on Dec. 13, then sailing south to the Rio de la Plata vainly probed the estuary, seeking the strait. On March 31 he reached Port St. Julian in latitude 49° 20' S., where on Easter day at midnight a serious mutiny broke out led by Spanish captains against the Portuguese commander. Magellan with resolution, ruthlessness and daring resourcefulness quelled it, executing one of the captains and leaving another to his fate ashore when, on Aug. 24, 1520, the fleet left St. Julian.

Discovery of Strait of Magellan and the Traverse of the Pacific.—After reaching the mouth of the Santa Cruz, near which "Santiago," reconnoitring, had been wrecked earlier, Magellan started south again, on Oct. 21 rounding the Cape of the Virgins, and at approximately 52° 50' S. entered the passage which proved to be the strait of his seeking, later to bear his name. "San Antonio" having deserted, only three of his ships reached the western end of the passage; at the news that the ocean had been sighted the iron-willed admiral broke down and cried with joy.

On Nov. 28 "Trinidad," "Concepción" and "Victoria" entered the "Sea of the South," from their calm crossing later called the Pacific ocean. Tortured by thirst, stricken by scurvy, feeding on rat-fouled biscuits, finally reduced to eating the leather off the yardarms, the crews, driven first by the Humboldt current and throughout the voyage by the relentless determination of Magellan, made the great crossing of the Pacific. Till Dec. 18 they had sailed near the Chilean coast, then Magellan took a course north-westward; not till Jan. 24, 1521, was land sighted, probably Puka Puka in the Paumotu archipelago. Crossing the equinoctial line at approximately 158° W. on Feb. 13, the voyagers made first landfall on March 6, when at Guam in the Marianas they obtained fresh food for the first time in their traverse of 99 days. A *Memorial*, sent by Magellan to King Charles before leaving Spain, suggests that he knew (probably partly from Serrão's letters) the approximate position of the Moluccas; in sailing now from the Marianas to the Philippines instead of direct to the Spice Islands, he was doubtless dominated by the idea of early re-victualing and the advantage of securing a base before visiting the Moluccas.

Death; Estimation of Achievement.—Leaving on March 9, Magellan's course west-southwestward now brought him to islands later called the Philippines, where at Massava he secured the first alliance in the Pacific for Spain; at Cebu the conversion to Christianity of the ruler and his chief men; but on Mactán Island, April 27, 1521, Magellan was killed in a fight with natives.

After his death only two of the ships, "Trinidad" and "Victoria," reached the Moluccas; only one, "Victoria" (85 tons), returned to Spain, under command of Elcano, originally master in "Concepción," and participator in the mutiny at Port St. Julian. For bringing home, on Sept. 7, 1522, the leaking but spice-laden ship, with only 17 other European survivors and 4 Indians, "weaker than men have ever been before," Elcano received from the emperor an augmentation to his coat of arms, a globe with inscription "Primus circumdedit me" ("You were the first to encircle me"). It had been left for Elcano, returning by the Cape route, to give practical proof of the sphericity of the earth.

The supreme distinction of Magellan lies not in any feat of circumnavigation but in his bold conception and masterly direction of the enterprise which achieved that feat. The first navigator to cross the Pacific from east to west, he disproved the prevailing idea that a few days westward sailing from the new world would bring ships to the Indies of the east, and he brought a fleet for the first time, sailing westward, within easy distance of them. Magellan, with a character so complex and of such extreme contradictions, will remain an enigma; psychologically he cannot have been at unity with himself. For his transference of allegiance many writers have denounced him, bearing in mind that in his time the loyalty of a Portuguese to his sovereign was only second to his loyalty to his God; others have pointed out that in offering his services to another ruler Magellan did what Columbus, Cabot and Vespucci had done, and that limitations imposed by nationality are irreconcilable with the advancement of knowledge. But on one thing all Portuguese are agreed: "he is ours."

The fullest account of the voyage is that of Antonio Pigafetta, knight of Rhodes, native of Vicenza, who sailed with Magellan and returned with Elcano. The true text of the Italian version, translated, edited and annotated by J. A. Robertson, is in *Magellan's Voyage Around the World* by Pigafetta, two volumes (1906). The *First Voyage Round the World* by Magellan, Hakluyt society, vol. lii (1874), includes, as well as Pigafetta's account, the following by other members of the expedition: *Diary of a Genoese Pilot* (believed to be Leon Pancaldo of Savona); the narrative of the *Portuguese Companion of Edoardo Barbosa* (probably Vasco Gomes Galego, of Bayona, Galicia); the *Log-Book of Albo the Pilot*, commencing Nov. 29, 1519, and recording on the return voyage the discovery in Cape Verde Islands that by sailing continuously westward a day had been "lost." This volume also contains the account of a contemporary writer, the *Discourse of Giovanni Battista Ramusio*, and Gaspar Correia's account of the voyage (taken from *Lendas da Índia*, vol. ii, cap. xiv).

(M. ML.)

MAGELLAN, STRAIT OF (Spanish ESTRECHO DE MAGALLANES), a channel, named for its discoverer, Ferdinand Magellan (*q.v.*), at the southern extremity of South America between the mainland (Magallanes; *q.v.*) and Tierra del Fuego (*q.v.*). It connects the South Atlantic and Pacific oceans and follows a winding course of about 360 mi. with widths varying from 2 to 20 mi.

MAGELLANIC CLOUDS (named after Ferdinand Magellan), two cloudlike condensations of stars in the southern sky. The Large Cloud is in the constellation Dorado at right ascension 5 hr. 26 min., declination -69° ; the Small Cloud in Tucana at right ascension 0 hr. 56 min., declination -73° . They are two companion galactic systems to the Milky Way, consisting of myriads of stars and many gaseous clouds; they are located at a distance of about 140,000 light-years from the sun, and are visible to the unaided eye for observers located in the southern hemisphere.

MAGEN DAVID (MOGEN DOVID), the "shield of David," a six-pointed star formed by two crossed triangles, is a Jewish symbol that appears on synagogues, tombstones and on the flag of the state of Israel. The symbol originated in antiquity when, side by side with the five-pointed star, it served as a magical sign or as decoration. In the middle ages the six-pointed star appeared with greater frequency among Jews without assuming a special religious significance; it is found, as well, on some medieval cathedrals. The term "shield of David" developed among medieval mystics who attached magical powers to King David's shield. Practical (magic) Cabala popularized the use of the *Magen David* as a protection against evil spirits. From the 17th century on, it became the official seal of Jewish communities and a generally used Jewish sign. Franz Rosenzweig interpreted the meaning of the two triads to be God, world, man and creation, revelation and redemption.

See G. G. Scholem, "The Curious History of the Six-Pointed Star," *Commentary*, vol. viii, pp. 243-251 (1949). (N. N. G.)

MAGENDIE, FRANÇOIS (1783-1855), French physiologist and father of experimental pharmacology, was born at Bordeaux on Oct. 6, 1783. He graduated M.D. at Paris in 1808 and, while prospector of anatomy, demonstrated in 1813 the passive role of the stomach in vomiting and investigated the action of emetics. His pioneer work on the localization of the site of drug action laid the scientific foundation for the introduction into medical practice of such drugs as strychnine and morphine. With P. J. Pelletier he discovered emetine in 1817. His announcement in 1822 that the anterior roots of the spinal nerves are motor in function and the posterior roots sensory led to prolonged controversy with Sir Charles Bell (*q.v.*), who claimed to have made the same discovery in 1811. From 1813 to 1831 Magendie taught experimental physiology privately, being appointed in the latter year professor of medicine at the Collège de France. Elected to membership of the Academy of Sciences in 1821, he was its president in 1837. A superb experimenter and a bold vivisectionist, Magendie founded the *Journal de physiologie expérimentale* (1821-31) and wrote *Précis élémentaire de physiologie* (2 vol., 1816-17) and *Formulaire pour la préparation et l'emploi de plusieurs nouveaux médicaments* (1821). Magendie is commemorated by the "foramen of Magendie" in the brain (1828). He died at Sannois, near Paris, on Oct. 6, 1855.

See J. M. D. Olmsted, *François Magendie* (1945). (WR. R. B.)

MAGENTA, a town of Milano province in Lombardy, Italy, lies 364 ft. above sea level and 16 mi. W. of Milan by rail in an industrial and agricultural region. Pop. (1961) 18,533. The town increased greatly after World War II. Its chief buildings are the cathedral, with a façade of Carrara marble, the commercial high school, the stadium, and the ossuary containing the remains of 9,000 killed at the battle of Magenta (June 4, 1859). There is a public park with a zoological garden. Magenta is a communications centre between Milan and Turin and its chief industry is the making of matches while other factories produce artificial silk and door locks.

Magenta derives its name from Marcus Maxentius, a Roman general and emperor (306-312), who had his headquarters there, at Castra Maxentia. Historically the battle of Magenta, which resulted in a victory for the Franco-Sardinians under Napoleon III over the Austrians, represented an important step toward Italian national independence. (G. CI.)

MAGGIORE, LAKE (Italian LAGO MAGGIORE; ancient VERBANUS LACUS), the second largest lake in Italy, has an area of 212 sq.km. (82 sq.mi.). It is bisected by the border between Lombardy (east) and Piedmont (west). Its upper end, 42 sq.km. (16 sq.mi.), is in the Swiss canton of Ticino. Lake Maggiore is 40 mi. long; its greatest width is $5\frac{1}{2}$ mi.; greatest depth, 1,220 ft. The surface is 636 ft. above sea level. The Ticino flows through the lake from north to south, on its way to the Po; the Toce comes in on the west from the Swiss Valle d'Ossola below the Simplon pass; the Tresa enters from the Lake of Lugano on the east. Locarno, at the northern or Swiss end, is 14 mi. S.W. of Bellinzona by rail on the St. Gotthard line. A railway was built along the southeastern shore, from Magadino, Switz. (10½ mi. S.W. of

Bellinzona), to Sesto Calende, Italy, at the southern end of the lake and 20 mi. by rail from Novara. The eastern shore is reached at Luino, Italy, by electric railway from Ponte Tresa on the Lake of Lugano (8 mi.), while the direct Simplon line runs along the western shore for 15½ mi. from near Pallanza past Baveno and Stresa to Arona, which is 23 mi. by rail from Novara. On the eastern shore are Luino and Laveno; on the western shore, from north to south, are Cannobio, Pallanza, Baveno, Stresa and Arona. Opposite (southeast) Baveno are the famous Borromean Islands (*q.v.*), while southwest of Baveno rises the glorious viewpoint of Monte Mottarone (4,892 ft.) between Lake Maggiore and the Lake Orta. (G. KH.)

MAGH, a term applied to immigrants from Burma long settled in the southeast districts of Bengal. Apparently of Tai origin, they entered Bengal from Arakan toward the end of the 18th century. Most of them came under Bengali influence, but in the south of the Chittagong Hill Tracts district of East Pakistan (*see* CHITTAGONG), where their culture remains comparatively pure, the script and dress are Burmese and the language an Arakanese dialect. Elsewhere the Bengali dress and language prevail. The religion of the Arakanese-speaking Maghs is animistic Buddhism; it persists especially in the Chittagong Hill Tracts district, where Buddhists numbered more than 275,000 (in a total population of 385,079) in the 1961 Pakistan census. The people are divided into endogamous clans and in modern times there were still strong traces of a political organization under clan chiefs, the most powerful of whom are known as the Bohmong and the Mong Raoja, the former being a lineal descendant of the Mon (*q.v.*) kings of Pegu. In the hills shifting cultivation was still preferred to plow agriculture in modern times, but the villages, containing from 10 to 50 houses, were invariably built on the banks of streams. The houses were flimsy structures on bamboo piles and a relic of the communal house for men was sometimes found in the form of a roofed platform built at the end of the village street.

See J. M. Ghosh, *Magh Raiders in Bengal* (1961); Office of the Census Commissioner, Karachi, *Population Census of Pakistan* (1961). (J. P. M.; X.)

MAGI (singular Magus), members of an ancient Persian clan specializing in cultic activities. Their name is the Latinized form of *Magoi* (e.g., in Herodotus i, 101), the ancient Greek transliteration of the Iranian original. It is disputed whether the Magi were from the beginning followers of Zoroaster and his first propagandists. They do not appear as such in the trilingual inscription of Bisitun (Bisutun), in which Darius the Great describes his speedy and final triumph over the Magi who had revolted against his rule (522 B.C.). The Magi were a priestly caste during the Seleucid, Parthian and Sasanian periods; later parts of the Avesta, such as the ritualistic sections of the Videvat (Vendidad), probably derive from them. From the 1st century A.D. onward the word in its Syriac form (*Magusai*) was applied to magicians and soothsayers, chiefly from Babylonia, with a reputation for the most varied forms of wisdom. As long as the Persian empire lasted there was always a distinction between the Persian Magi, who were credited with profound religious knowledge, and the Babylonian Magi, who were often considered as impostors (*see* also PERSIAN HISTORY: Sasanian Empire).

The connection of the Magi with astrology and their oriental origin is all that is known of the "Magi [rendered "wise men" in most English Bibles, "astrologers" in the New English Bible] from the east" who came, guided by a star, to worship the infant Jesus as king of the Jews (Matt. ii, 1-12). Christian theological tradition has always stressed the fact that gentiles as well as Jews came to worship Jesus, an event celebrated in the Eastern Church at Christmas and in the west at Epiphany. In early Christian art the Magi usually wear Persian clothes (e.g., the catacombs of Priscilla in Rome, 2nd century). The names Gaspar, Melchior and Balthasar are first mentioned in the 6th century. Their number is generally 3 (that of their presents of gold, frankincense and myrrh) but is sometimes given as 12. In the Syriac apocryphal tradition some of those names are Persian and they are connected with Persian religious history. As early as the 3rd century they began to be thought of as kings. Their supposed relics

were transferred from Constantinople to Cologne (*q.v.*) in the 12th century.

MAGIC. Etymologically the term "magic" is derived from the Greek *mageia* and the Latin *magia*, used by classical writers to describe the occult learning and practice of the Persian Magi (*q.v.*). As this was supposed, for example by Plutarch, to have included offering sacrifices to Ahriman, the creator of evil in Zoroastrian belief, "magic" acquired a sinister significance and became associated with witchcraft and the "black arts" in their many grim manifestations. Sorcery, that is the use of spells or the illicit obtaining of predictions, and necromancy, that is the calling up of the dead for consultation, are terms that have acquired a similar meaning. While the article MAGIC, PRIMITIVE, deals with the subject as the anthropologist sees it, the present article will be concerned chiefly with magic in Europe considered as the illicit trafficking with the occult and with the supernatural forces in the perennial struggle between good and evil. Magic exercised to promote well-being is sometimes called white magic to distinguish it from black magic, which is exercised malevolently or with a deliberate appeal to demoniacal forces of evil. For the forces of evil *see* preliminarily DEMON; DEVIL. For "magic" as a form of theatrical entertainment, *see* CONJURING.

Irrational as it may be, the magic art yet has an efficacy beyond dispute within its own sphere of operation, namely where emotional and incalculable elements are predominant. It supplies powerful supernatural sanctions reinforced by a mythological tradition which, even in the higher civilizations, can exert a strange fascination, not least when it functions in a diabolical setting of hate, fear, cruelty and malice.

The pagan Roman emperors lived in terror of sorcery and took measures against it; and in the 2nd century A.D. Lucius Apuleius, author of the famous romance on the subject, *Metamorphoses* or *The Golden Ass*, was himself charged with the practice of malevolent and immoral magic. For the rationalists of the Greco-Roman world, however, whether Skeptics, Epicureans or Cynics, everything that savoured of the marvelous was to be attacked as magic, and all those engaged in any kind of traffic with the unseen were declared to be sorcerers, charlatans and rascals. The Christian church, on the other hand, was very far from denying the reality of the spiritual forces at the command of those who worked the magic arts. Since Persian Magi, through their astrology, had been among the first to discover Christ, the reality of magic was beyond question; but it was liable to grave abuse. Origen, St. Augustine and the early Fathers in general were convinced that magicians were in league with the Devil and his demons in a great struggle against the good; and indeed the pagan gods themselves were regarded by the Fathers as standing in the same magic tradition, together with the Gnostics and other contemporary heretics. Magicians therefore ought to be destroyed as malicious demons or their agents, and not merely dismissed as hypocrites or charlatans. Thus the Simon who, according to the narrative in the Acts of the Apostles (viii, 9-24, which may be an interpolation), had bewitched the people of Samaria by his sorcery and been severely rebuked by St. Peter and bidden to repent for trying to purchase miraculous supernatural power from the disciples, was regarded by Christians as early as the 2nd century as a false Messiah who practised magical arts (*see* SIMON MAGUS).

Believing itself to be challenged by an organized movement of adepts with Gnostic affinities who practised necromancy in opposition to Christianity and its doctrine of redemption, the church devised its own office of exorcism (*q.v.*); and on the fringes of Christendom, where Gnostic influences were firmly entrenched, as for example among the Copts, spells, sometimes containing the magical names of particular spirits, were employed to ward off attacks of demons. But the attempt to deflect the powers of evil by quasi-magical constraint and compulsion readily gave place to

methods of persuasion, which in turn led to making a bargain or pact with the Devil. Instances of the pact occur from the 4th century onward, but the most celebrated case in popular mythology is that of Faust (*q.v.*), to which moreover elements of the story of Simon Magus made some contribution. The identification of pagan deities with demons further resulted in the notion of aerial flights by women with Diana or Hecate, and this was readily extended to flights with Herodias and other diabolical figures. Incubi and succubae were demons supposed to visit women and men respectively for carnal intercourse.

The revival of Gnostic or Manichaean dualism in Europe by the Bogomils (*q.v.*) from the 10th century onward in the east and by the Cathari (*q.v.*) subsequently in the west is another factor to be considered in relation to the medieval development of diabolical magic. These highly organized heretical movements insisted on the power of Satan over the material world and over the human body and denounced the church as "the synagogue of Satan," not least because of its sacrament of marriage, which they regarded as a preposterous disguising of the sinful as the holy. Whether or not these heretics were involved in magical practices (as the church alleged), their dogmatic condemnation of the flesh seems to have led to licentious practices, if not among their genuine converts at least among their more ignorant listeners, since the general subjection of the physical world to Satan could be interpreted to mean that particular acts were matters of indifference so long as they were not blasphemously "sanctified" by marriage. The widespread theory of courtly love (*q.v.*), with its emphasis on an extramarital relationship, had its roots in Languedoc, the very region where the Cathari were strongest.

In this climate of opinion, with Satan's power emphasized and sexual licence condoned, it is not surprising that manifestations of the witch cult (see WITCHCRAFT) included debaucheries, atrocities and the worship of Satan in the "black mass." Margaret Murray's contention that the witch cult was a "Dianic" fertility religion surviving in Christendom from pagan times does not preclude its having degenerated in many cases, as persecution drove it underground, into a diabolism that fed its hostility to the Christian faith on elements culled from the great heresies or on express retroversion of the church's own teaching, rites and commandments. It should be remembered, however, that sometimes the charges brought against individuals by the Inquisition or by secular authorities as evidence of heresy or witchcraft included offenses which might have had other motives in fact (orgies need not always be ritual).

Essentially, the black mass is a blasphemous and obscene burlesque of the true Mass: a renegade priest or some other "adept" performs it (with a validly consecrated Host surreptitiously abstracted from church for the purpose if the celebrant himself is not a priest), sometimes with a woman's naked back for his altar. For the private purposes of believers, whether aphrodisiac or lethal, procedures akin to the "sympathetic" magic of primitive peoples are followed by the Satanist: philtres or abortifacients can be compounded of *genitalia*, herbs and bones; and bones may be pointed or set in a symbolical pattern against an intended victim, or a waxen effigy of him, preferably containing something of his (such as a strand of hair or a nail paring), may be melted or skewered.

Incantations and spells may comprise not only strange words perhaps derived from the extinct languages of pagan Europe but also names of Gnostic, Hebrew or Arabic origin, since Jews and Muslims were "infidels" in the eyes of the church (and the Cabala, in particular, could easily be perverted). The *Pater noster* can be recited backward to invoke the Devil. Likewise the tetragrammaton, that is, the four characters of the name of God in Hebrew, can be written backward for use as a supremely potent symbol. Other symbols exploited are the circle (ensuring the magician himself against the malevolence of the spirits invoked), the pentacle and the signs of the zodiac; and some terminology or ideas may be borrowed from alchemy. Before being initiated into this esoteric lore, one may be required to perform some outrageously degrading or even criminal act as a test of total submission to evil.

Black magic and the fear of it did not die out with the middle ages. In England an act of 1542 made witchcraft, sorcery and enchantment punishable by death; and though this act was repealed in 1547, a new one, passed in 1563, remained in force till 1736. In the France of Louis XIV the Affair of the Poisons (*q.v.*) was almost entirely concerned with recourse to black magic. Well-intentioned movements such as Rosicrucianism (*q.v.*) and the development of speculative masonry (see FREEMASONRY) may have diverted into philanthropy many who would otherwise have been tempted by the mystery of the magician; and the "enlightened" rationalism of the 18th century tended to reduce black magic to a joke in which freethinkers such as Sir Francis Dashwood and his friends of the Hell-Fire club could indulge. Yet on the one hand John Wesley in 1768 could maintain that to suffer a witch to live was to surrender belief in the Bible's infallibility, and on the other hand such wonder workers as Cagliostro enjoyed a high prestige.

Romanticism in the 19th century counteracted skepticism, and the violinist Paganini was even reputed to owe his virtuosity and his successes to a pact with the Devil—a rumour that his sorrowful countenance did not belie. Of 20th-century magicians the most notorious was Aleister Crowley (1875–1947), who devoted his fortune to the practice and propagation of his doctrine "*Do what thou wilt shall be the whole of the law.*"

MAGIC, PRIMITIVE. Magical beliefs and practices are widespread in primitive society, and tend to persist even when primitive cultures are changed by contact with more complex industrial economies. The term "magic" covers a great range of activities, from practices intended to promote the fertility of crops or secure game to the hunter to the use of love philtres and other devices to attract members of the opposite sex and conjurations to cause the death of an enemy. The importance of magic in primitive societies has provoked an extensive theoretical literature in which E. B. Tylor, J. G. Frazer, E. A. Westermarck, H. P. E. Hubert, M. Mauss, R. R. Marett and B. K. Malinowski have taken a prominent part.

Many attempts have been made to distinguish between magic and religion. Frazer and others contrasted the direct control exercised by man through the use of magic with the propitiation he offers to higher powers in prayer. Magic has been supposed to rely upon powers of an impersonal order (such as mana [*q.v.*], a supernatural power that can inhere in both persons and things) which Marett, Hubert and Mauss regarded as the basis of magic, while religion was thought to call upon personal spirit powers. É. Durkheim postulated that magic is essentially an individual affair, whereas a congregation or church is characteristic of religious worship, and that the magician is an isolated man without the professional training and standards of a priest. To Malinowski magic was essentially a pragmatic art concerned with the attainment of practical needs, whereas religion related to more general and far-reaching affairs, which have no immediate solution but give meaning to the basic problems of human life, fate and death.

However, it came to be realized that the distinction between magic and religion could not be drawn as sharply as these definitions suggest; for instance, some magical spells are addressed to spirit beings, many magic rites take place before an assembly of people, and many magicians receive training and are members of a respected profession. Some anthropologists, therefore, have preferred to speak of a "magico-religious" category of phenomena. Nevertheless, it is convenient to class together those ritual actions which hinge on the direct, commanding use of spells or of medicines believed to be efficacious in their own right, and concerned with some immediate objective which is thought unobtainable by technical means alone (see SOCIAL ANTHROPOLOGY: *Ritual Relations*).

In essence, magic is a symbolic mode of ritual; at every step theory and dogma are translated into action, both verbal and non-verbal. In *Coral Gardens and Their Magic* Malinowski gave an elaborate analysis of primitive magic among the Trobrianders, who live off the east coast of New Guinea. According to him every act of magic is characterized by things said, things done and a person officiating; hence the spell, the rite and the condition of the performer are the fundamental elements. Other writers such as E. E. Evans-Pritchard have pointed out that in many parts of Africa, for example, magical substances known as medicines are also of great significance.

Elements of the Magical Art.—Spells.—In Melanesia and many other communities the spell, the uttering of words in a set formula, is regarded as the vital part of the magical act. In fact, magic has even been defined as "all the formulae for doing things beyond one's personal powers." Among some peoples the virtue of the magic resides so entirely in the formula, believed to have been handed down from immemorial antiquity, that the word for spell may be used to mean magic as a whole, as the Maori *karakia* or the Trobriand *megwa*. In some communities a correct recital of the formula is regarded as necessary to make the magic effective; the Maori held that any slip in the recital not only nullified the magic but might even cause the death of the practitioner. (The actual situation was usually the reverse: if a magician died it was often thought to be due to his reciting the spells incorrectly.) Such fixed formulas are in contrast with the free formulas in vogue among some other Polynesians, such as the Tikopia (Solomon Islands). There the person reciting the spell uses conventional phraseology, but is allowed to modify it as seems best to him; this is not held to affect the virtue of the magic.

The language of magical formulas is sometimes archaic and not always understood by the reciter. Meaningless terms of the abracadabra variety are believed to be efficacious because of their traditional value. Much magical language, however, is clearly and directly correlated with the aim of the recital. In symbolic statement by analogy it represents and foreshadows the technical achievement, and metaphor and simile are freely used. A Maori spell to give speed and grace to a canoe, for instance, speaks of the swiftness of a bird on the wing, the lightness of a sea gull floating on the water, and gives the names of a number of woods noted for their buoyancy. An onomatopoeic effect is also introduced, such as speed noises or the wailing of the sea. A Tikopia formula to facilitate the manufacture of turmeric (a red dye) refers to the blood-red flowers of the coral trees, the red leaves of a palm, red ginger and blood-hued fish, all analogies designed to intensify by association the quality of the pigment. In some cases traditional and mythological events are mentioned and ancestral names recited; this, along with the cryptic and archaic language of some of the phrases, makes the spell obscure to all who have not been trained in its lore.

Although many magical formulas are compulsive or mandatory, some are intended to control by persuasion: in Tikopia spells used for fishing entice the fish with various flattering suggestions, including appeals to their pride. In other forms of magic, the verbal element is merely a descriptive explanation relating the magical acts to the desired end.

Medicines.—The term medicine is often applied to an object in which mystical power is supposed to reside and which is used in a magic rite; hence the term medicine man sometimes popularly used for a magician. Many such medicines are employed for their supposed therapeutic effect, but many are thought to have other virtues and some are actually poisonous. The magical practitioner and his clients are often unaware of the real nature of the "medicine" they are using; for example, a member of the Azande (*q.v.*) tribe of central Africa will observe tabus and ritually address fish poisons before throwing them into the water; in the same way he addresses a crocodile's tooth while he rubs the stems of his bananas with it to make them grow. The fish poison really does paralyze the fish, while the crocodile's tooth has no effect upon the bananas. Yet to the Azande the two are equally potent.

Although many medicines are made from vegetable substances,

their sources are quite diverse. The Azande include as medicines magical wooden whistles which they use as a protection against witchcraft or to damage an enemy. Other types of medicines *e.g.*, some of those used in Africa and Malaya, are of animal bone, gallstone, tooth or horn, or of mineral substances such as quartz crystal. The magical substance is often associated symbolically with the desired object or quality; when magic rites are performed over a Trobriand canoe, pieces of dried banana leaf and other very fragile plants are used, symbolizing the idea that the canoe should be as light as possible in the water, to give it speed.

Rites.—Usually a magical formula is accompanied by a rite or set of bodily actions, that functions primarily to associate the spell or medicine with its target. In a Tikopia rite to kill wood borers in the timber of a canoe the gunwale is struck lightly with a ritual adze. It is believed that the pests will be killed by the spirit guardians of the adze, but that the tapping is necessary to mobilize and direct their power to its objective. Sometimes the rite symbolizes the end desired, as when water is sprinkled on the ground during the recital of a rain-producing formula, or the burning of an image accompanies magic intended to afflict an enemy with burning pains. The rite, like the spell, is usually prescribed in a set form, and is often parallel to the verbal recital. It is then both the vehicle of the spell and the translation of word into action.

Conditions of Performance.—Since it is thought that magic must be treated with great care, because of its supposed supernatural associations and practical value, the condition of the performer is usually of great significance. He is commonly hedged around by tabus; for instance, he may have to refrain from eating certain foods, from sexual indulgence and from whatever might contaminate him. If he fails to conform, then he nullifies the power of his act; breach of tabu (*q.v.*) is the cause most frequently assigned for the failure of magic.

Malinowski laid great stress on the performer's simulation of the real act and held that magic is a ritualized expression of desire which cannot be fulfilled by technical means and which finds outlet in speech and gesture. For example, in the rite of black magic in which a bone or dart is pointed at a victim, the magician twists and turns, gestures in the air and assumes a state of excitement and fury as if he actually were stabbing his enemy. Malinowski perceived a spontaneous outburst of word and act as the germ of spell and rite, and in the illusion of subjective experience (the conviction that such actions have really had their effect) he saw the foundation of belief in magical efficacy. While belief in the power of symbolic action is undoubtedly basic in magical thought, he seems to have overstressed the individual and emotional aspects of much magical behaviour. It is often a routine, calmly performed and conforming to socially accepted rules, rather than a procedure in which the emotions of the performer are very manifest. Malinowski's view was a useful corrective to the earlier intellectual analyses, but it paid too little attention to the place of magic as a symbolic, ideational system.

Primitive Magic and Science.—According to Tylor, the great pioneer in anthropology, magic developed from the thought processes of primitive man by means of association of ideas, becoming organized into an elaborate and systematic pseudoscience. This position was more explicitly formulated by Frazer, who regarded magic as man's attempt to formulate a body of principle by which the future might be determined. In the popular view, magic is often thought of as a fraudulent art (*see CONJURING*) which pretends to an occult control of nature or of spirits, and the falsity of its claims is emphasized. Contrary to the latter view, magic normally is not performed in a spirit of pretense; some primitive magicians do occasionally cheat, but neither they nor their public regard this as invalidating the claim of magic as a whole.

Neither Tylor's nor Frazer's theory takes into account that though the immediate context of magic and science may be the same, their procedures are different and they apply to different aspects of the same general problem. Malinowski, by his analysis of garden magic in the Trobriands, showed just how different the aims of the magical and agricultural processes are. The Trobriander has a good empirical knowledge of soils and plant growth.

of wind and weather, and is well aware that careful tillage, weeding, repairing of fences and replacement of damaged seeds are essential for a good harvest. On the other hand, there are conditions with which his knowledge and technique cannot cope, and to secure the right amount of rain and sun, to avoid insect pests or failure of the crop by disease, he uses magical aid. The islanders resort to magic where human knowledge and skill fail.

The outside observer knows that the sky will not produce rain in reply to sympathetic rites and that animals will not come to the hunter because of a spell; therefore, though he concedes that the field of operation of magic is often different from or beyond that of science, he will still ask why the fallacy of this "mumbo jumbo" is not exposed and why "the whole monstrous farrago," as Tylor called it, is not discarded as futile. One reason is that the false ritual of magic is often combined with valid technical practices; for example, the Azande use of fish poisons, described above, and others of a therapeutic character. Some primitive magic is experimental, rejecting one medicine in favour of another until the desired effect is obtained. Sometimes it may be difficult to say whether a procedure is magical or scientific, as when Polynesians use a rattle of coconut shells accompanied by a ritual formula to attract sharks. Sometimes success is simply a matter of chance, aided by the shrewdness of the magician in selecting an opportune moment for the exercise of his art. Moreover, when there is already a predisposition to believe in the validity of the claims advanced, men are prone to attach great significance to successful cases and ignore negative instances. In retrospect, one success may count more than a dozen failures. Important, too, is what Malinowski called the "current mythology of magic": stories of the prowess of particular magicians, which exaggerate their powers and credit them with causing events for which they were in no way responsible. Even when failure of magic is admitted in a particular case, men often protect the institution as a whole by explaining the failure as due to even more powerful counter-magic.

Magic is thus not simply an irrational system of ideas and practices, an ineffective substitute for science by which it might be easily replaced. The difference between magic and science lies in their basic premises. Magic, unlike traditional science, is based on the assumption that words and actions technically unrelated to a phenomenon can exert a physical effect. All magical practices are derived quite logically from this belief.

Functions of Magic.—Though magic may not be capable of achieving the aims which its practitioners believe, it is not without effects of a different kind. It can be considered conveniently in three categories: productive, protective and destructive. By its ritual importance, productive magic, which is concerned with bringing about a good harvest, a catch of fish, etc., may help to organize the technical side of the activity, to stimulate the workers to keener effort and to give them more confidence that their efforts will be rewarded. Protective magic, that which aims to ward off danger and misfortune or to cure an illness, may give the confidence necessary for success or the reassurance which will speed recovery. Some of the effects of magic are negative: those who rely on productive magic fail to exert their scientific curiosity and to strive for technological developments. The ritual practice of destructive magic is often termed sorcery, in contrast with witchcraft, which is believed to spring from the specific endowment or disposition of an individual. It is often a source of social control, for sometimes those in authority fear it will be used against them; on the other hand, it may serve as a cathartic measure which, by allowing a person to destroy an enemy in imagination, averts a real act of violence. For these reasons, magic has occupied an important place in most primitive societies and maintains a certain degree of its influence despite the challenge offered by modern conditions. See also ANIMISM; EVIL EYE; SHAMANISM; WITCHCRAFT; MAGIC; SUPERSTITION; VOODOO.

MAGIC SQUARE, an arrangement of numbers in the form of a square so that every column, every row and each of the two diagonals add up alike, this sum being called the constant. Strictly speaking the numbers used should be consecutive from 1 up to n^2 , where n is the number of cells (or squares) in any side. Such an arrangement of n^2 numbers is called a square of the n th order.

FIG. 1.—TYPES OF MAGIC SQUARE

Thus fig. 1(A) complies with all the conditions and is a magic square of the 3rd order. These squares are of great antiquity and appear to have been known from very ancient times in China and India, where, as at the present time, magic squares were worn engraved on metal or stone as amulets or talismans. They appear to have been introduced into Europe early in the Christian era; an early writer on the subject was Manuel Moschopoulos, a Greek of uncertain date who lived in Constantinople, probably about 1300 A.D. His work in manuscript is in the National library in Paris (manuscript no. 2,428). Heinrich Cornelius Agrippa (1486–1535) constructed squares of the orders 3, 4, 5, 6, 7, 8, 9, which were associated with the seven astrological "planets," Saturn, Jupiter, Mars, the sun, Venus, Mercury and the moon. The magic square of the 4th order shown in fig. 1(B) is to be seen in Albrecht Dürer's engraving "Melancholia." The date of the work (1514) is indicated in the two central cells of the bottom row, but whether this was intentional or a mere coincidence is not known. In later times the subject has been investigated as a mathematical curiosity, and more recently as an aid in the design of scientific experiments; it has large though scattered literature of its own. The three main lines of inquiry are construction, classification and enumeration.

Construction.—It is convenient to deal with these squares in three classes. Those of an odd order, those of a doubly-even order (that is where n is of the form $4m$) and those of a singly-even order (where n is of the form $2[2m + 1]$). These vary in difficulty in their order. The smallest possible square of an odd order is, of course, that of the 3rd order shown in fig. 1(A), to which there is that one fundamental solution only. Eight different arrangements may be obtained by merely turning the page around and also turning it around in front of a mirror. These so-called reversals and reflections are not usually counted as different. A square of the odd order may immediately be written down in the manner shown in fig. 1(C), described by Antoine de la Loubère after an old Hindu method. Begin with all cells in the square empty, and enter numbers in sequence starting with 1. Start at the central cell in the top row and proceed diagonally upward to the right. Since the 2 is outside the square bring it to the bottom of its column, thus giving it the position it occupies on the outside square. After the 3 is written, the 4 falls outside the square, and it is inserted at the opposite end of the row and the 5 is entered. Since the next square is occupied by the 1 write the 6 beneath the 5 and proceed until the 10 falls outside the square and so on. It will be noted that 16 falling outside the square at a corner is written beneath the 15 as in the case of an occupied square. This can be applied to any square of an odd order; but, as so many methods that have been adopted, it produces only one type of square, though it may be modified to form a limited number of other squares. Thus it is possible to start with the 1 in any cell and always get a square that has magic properties in rows and columns, but not necessarily in the diagonals. C. D. Bachet (1612) used a somewhat similar method. Another method, adopted from an

FIG. 2.—DE LA HIRE'S METHOD OF CONSTRUCTION

old Asian technique by Philippe de la Hire, may be used for the construction of squares of any order. He employed three subsidiary squares though one of these has been dispensed with by later writers. In fig. 2(A) the numbers 1, 2, 3, 4, 5, are arranged so that every number appears once and once only in every row and column, and in one diagonal, the other diagonal having repetitions of 3. In fig. 2(B), the numbers 0, 5, 10, 15, 20, are similarly treated only the repeated 10s are in the other diagonal. These squares superimposed and added produce fig. 2(C), which is a perfect magic square. Similar methods have been devised for the construction of magic squares; some of these will be found in the books named in the *Bibliography*. But most of the writers on the subject develop their own favourite schemes.

Classification.—This is a matter of individual taste and may be called the elegant branch of the subject. Taking the case of

FIG. 3.—MAGIC SQUARES OF THE 4TH ORDER

the 4th order the solutions can all be classified under the four types shown in fig. 3.

The Nasik square (so named by A. H. Frost after the town in India where he lived, and invented by Islamic scholars in ancient Persia) is the most perfect type conceivable. Here all the broken diagonals sum to the constant 34. Thus, for example, $15 + 14 + 2 + 3$ and $10 + 4 + 7 + 13$ and $15 + 5 + 2 + 12$. As a consequence if the square is repeated in all directions, a 4×4 square may be marked off anywhere and it will have magic properties.

In the case of the associated squares every number if added to the number that is equidistant in a straight line from the centre gives 17; thus $1 + 16$, $2 + 15$, $3 + 14$ and so on. Dürer's square (fig. 1[B]) is also associated. The simple square is one that fulfils the simple conditions and no more. The semi-Nasik has the property that the opposite short diagonals of two cells together sum to 34; thus $14 + 4 + 11 + 5 = 34$, and $12 + 6 + 13 + 3 = 34$. In this order there are 48 Nasiks, 384 semi-Nasiks (which include 48 associated) and 448 simple, making a total of 880. The Nasik square is also sometimes called diabolique and pandiagonal and the semi-Nasik semidiabolique. Graphic illustra-

FIG. 4.—GRAPHIC SOLUTIONS OF TYPES OF THE 4TH ORDER

tions of each type are shown in fig. 4, if placed beneath the squares to which they apply.

Enumeration.—The very difficult question of enumerating the squares of the different orders has attracted the attention of many mathematicians but very little progress has been made during the last 250 years. Of the 3rd order there is only one fundamental arrangement as stated above. Of the 4th order there are 880 different fundamentals. These were all given by Bernard Frénicle

de Bessy in a posthumous work of 1693 and this has been frequently confirmed by later writers. It was shown in the *Queen* (Jan. 15, 1910) how the complete set might be so written out if desired (see also M. Frolov's *Carrés magiques*). No enumeration for larger squares has been completed. Particular types of squares, however, have been counted.

Greco-Latin Square.—A new type of magic square, the Greco-Latin square, was investigated in 1782 by the famous Swiss mathematician Leonhard Euler. Greco-Latin squares were shown to be useful for the design of statistically controlled experiments by R. A. Fisher in the early 1920s, and are widely used in agronomic, biological, medical, psychological and sociological research.

The two squares shown in fig. 5(A) and 5(B) respectively are

A	B	C	D
D	C	B	A
B	A	D	C
C	D	A	B

A

α	β	γ	δ
δ	γ	β	α
β	α	δ	γ
γ	δ	α	β

B

α	β	γ	δ
δ	γ	β	α
β	α	δ	γ
γ	δ	α	β

C

FIG. 5.—TWO ORTHOGONAL LATIN SQUARES OF ORDER 4 AND GRECO-LATIN SQUARE OF ORDER 4 OBTAINED BY SUPERPOSITION

examples of Latin squares of order 4. In the first of these squares each of the letters A, B, C, D occurs once in each row and once in each column. Similarly, in the second square each of the Greek letters α , β , γ , δ occurs once in each row and once in each column. These two squares further have the magic property (called orthogonality in modern terminology) that when superposed they yield the Greco-Latin square shown in fig. 5(C) in which each Latin letter occurs with each Greek letter in one and only one of the 16 cells.

In general, a Latin square of order n is defined as an $n \times n$ square, the n^2 cells of which are occupied by n distinct symbols (which may be Latin or Greek letters, or just plain integers) such that each symbol occurs exactly once in each row and each column. Two Latin squares are said to be orthogonal if on superposition each symbol of the first square occurs exactly once with each symbol of the second square, and the square obtained by superposition is called a Greco-Latin square.

For example, suppose there were four regiments A, B, C, D and in each regiment there were four officers or ranks α , β , γ , δ . Then the Greco-Latin square (fig. 5[C]) may be regarded as a solution of the problem of arranging these 16 officers in a 4×4 square, such that each regiment and each rank is represented in every row and every column. A similar problem for 25 officers can easily be solved. The problem of 36 officers, however, is another matter.

Euler showed that the problem of n^2 officers requiring the construction of a Greco-Latin square of order n can always be solved when n is odd, or when n is an evenly even number (i.e., n is of the form $4m$). On the basis of extensive trials Euler stated, "I do not hesitate to conclude that it is impossible to produce any complete square of 36 entries and the same impossibility extends to the cases of $n = 10$, $n = 14$ and in general to all unevenly even numbers." This became famous as Euler's conjecture, which may be stated as follows: There does not exist a Greco-Latin square of order $n = 4m + 2$ for any positive integer n .

In 1900 the French mathematician G. Tarry proved by exhaustive enumeration that Euler's conjecture was indeed true for the case $n = 6$, and the result was independently verified by R. A. Fisher and F. Yates. The amount of labour involved in the method of exhaustive enumeration increases extremely rapidly as n increases; to quote from a survey of combinatorial analysis by M. Hall: "Extensive searches on SWAC, the computer at UCLA, have failed to produce an orthogonal 10×10 pair. But even with more than 100 hours of high speed search, the part of the possible cases tried is so microscopic that no conclusion may be drawn." (M. Hall in *Some Aspects of Analysis and Probability* by I. Kaplansky *et al.*, John Wiley & Sons, Inc., New York, N.Y., 1958.)

Whether or not Euler's conjecture was true remained undecided for over 175 years. The question was finally settled in 1959 by the individual and collaborative efforts of three mathematicians, R. C. Bose, S. S. Shrikhande and E. T. Parker. To understand the developments which led to this result consider sets of more than two mutually orthogonal Latin squares. For example, the squares shown in fig. 5(A), 5(B) and 6 constitute a set of squares any two of which are orthogonal. Let $N(v)$ denote the maximum possible number of mutually orthogonal Latin squares of order v . H. F. MacNeish showed in 1922 that if v is a prime power then $N(v) = v - 1$; for example, $N(4) = 3$, $N(7) = 6$, $N(9) = 8$. Let $v = p_1^{a_1} p_2^{a_2} \dots p_m^{a_m}$ be the prime-power decomposition of v , and let $n(v) = \min(p_1^{a_1} - 1, p_2^{a_2} - 1, \dots, p_m^{a_m} - 1)$. For example, $12 = 2^2 \cdot 3$, and $n(12) = \min(2^2 - 1, 3 - 1) = 3 - 1 = 2$. MacNeish gave a method of obtaining $n(v)$ mutually orthogonal Latin squares of order v (see H. B. Mann in the *Bibliography*) and thus proved that $N(v) \geq n(v)$. He conjectured that $N(v)$ is actually equal to $n(v)$ so that not more than $n(v)$ mutually orthogonal Latin squares of order v can be obtained. Since $n(v) = 1$ if $v = 4m + 2$, the correctness of his idea implies the correctness of Euler's conjecture. However, MacNeish's conjecture was disproved by Parker who, among other things, showed that if $v = k^2 + k + 1$, and k and $k + 1$ are both prime powers, then $N(v) \geq k - 1$. MacNeish's conjecture is contradicted by taking $k = 4$, since $N(21) \geq 3$, whereas $n(21) = 2$. Though Parker's work did not disprove Euler's conjecture it cast a grave doubt on its correctness. Bose and Shrikhande obtained the first counter example to Euler's conjecture by deriving a Greco-Latin square of order 22, and gave a method by which infinitely many squares of orders of the form $4m + 2$ could be obtained. Following this Parker showed how to obtain Greco-Latin squares of order $12t + 10$ when $8t + 7$ is a prime power. This includes the important case of order 10, the square for which is shown as fig. 7. Finally the three authors collaborated in establishing that a Greco-Latin square of order $4m + 2$ can be obtained for all positive integral values of m exceeding unity. Euler's conjecture thus turns out to be false for all orders exceeding 6. See also COMBINATORIAL ANALYSIS.

MAGINDANAO, a Philippine language and a cultural group numbering about 200,000 persons in the 1960s, principally centred on the Cotabato river (or Rio Grande de Mindanao), Cotabato province, island of Mindanao. The word Magindanao denotes those who live near a flood area (the Cotabato floods daily and seasonally), and the name of the island derives from this group.

There are three groups of Magindanao, each with its own dialect; those who live along the delta, the lower valley and the south branch of the river are known as Sa Ilud ("down-river"); those from the northern branch and the interior reaches of the river are the Sa Laya ("up-river"). A third group, the Ilanun, are primarily concentrated on the coast north of the river mouth; the dialect spoken there reflects intimate contact with the closely related Maranao of Lanao province (see MINDANAO; COTABATO).

The language distinctions reflect other differences. The people of the lower valley are primarily sedentary wet-rice agriculturalists. Those in the upper valley are semisedentary, growing corn and dry rice. The Ilanun were formerly particularly active in trade and as pirates. The down-river area was dominated by the sultan of Magindanao before United States rule, while the ruler who controlled the up-river area was called the *radia* of Buayan; there were also a number of minor rulers. The Magindanao are Muslims (see MORO), having been converted to Islam in the 15th century. Until coming under Spanish control in the 19th century they were the most powerful group on the island, controlling a major portion of southern and central Mindanao and dominating the pagan groups for purposes of trade and tribute. They also had commercial and political relations with peoples in Borneo, Celebes and Malaya.

(M. Mx.)

MAGINOT, ANDRÉ (1877–1932), French statesman and one of the sponsors of the Maginot line, was born at Paris on Feb. 17, 1877. After studying political science and law, he entered the civil service and rose to be assistant to the governor general of Algeria in 1907.

In 1910 Maginot abandoned government service for politics, being elected to the chamber of deputies and, in 1913, becoming undersecretary of state for war. He was inducted into the army as a private at the outbreak of World War I, and was seriously wounded, being crippled for life. On his recovery, in 1916, he resumed his political career as a deputy and served as minister of colonies, pensions or war in six successive cabinets. During his last term as minister of war (Nov. 1929–Jan. 1931), he reorganized the army and directed the construction, on the French northeast frontier, of the system of fortifications named after him (see FORTIFICATION). He died at Paris on Jan. 7, 1932.

Maginot's name became a symbol of the belief in elaborate fixed defenses that dominated French military thought before World War II and stood in sharp contrast to German tactics that stressed rapid movement of tanks, planes and motorized infantry.

(M. V.)

MAGISTRATE, a title derived from the Latin *magister* ("master"), the holder of a public office (see CONSUL). It is still used in this sense, as, for example, when the highest officer in a community is referred to as its chief magistrate. More generally it is used to denote a minor judicial official whose duties may include: (1) acting as a judge at the trial of minor criminal matters; (2) the determination of the sufficiency of evidence to hold an accused for trial or for grand jury proceedings; (3) the determination of the amount of bail for a person so held for further proceedings; and (4) the issuance of warrants for search and for arrest.

See JUDICIARY AND COURT OFFICERS; JUSTICE OF THE PEACE; MAGISTRATES' COURTS.

(P. B. K.)

MAGISTRATES' COURTS in England and Wales have a criminal jurisdiction covering a wide range extending from small traffic offenses and public health nuisances to serious crime. With some offenses they deal completely; for other more serious ones they hold preliminary hearings, committing the accused for trial by a higher court if satisfied that there is a prima-facie case. For an intermediate class of offenses an accused person over the age of 14 years may elect to go to a higher court for trial by jury. The terms of imprisonment that magistrates' courts may impose vary with different offenses but normally do not exceed 6 months, or an aggregate of 12 where there is more than one charge. If the

magistrates, having tried an indictable offense, think that the record of the accused calls for a penalty beyond their powers, they may send him to quarter sessions for sentence. The great majority of criminal cases are dealt with by magistrates' courts. They also deal with a variety of civil and administrative matters. Normally an appeal lies from their decisions by way of a rehearing at quarter sessions or on a point of law to the high court. Most magistrates are unpaid laymen, but counties and towns may ask for the appointment of qualified stipendiary magistrates. On all but a few occasions, including committal proceedings, there must be at least two lay magistrates sitting. They are advised on law and procedure by clerks who normally have a legal qualification. Stipendiary magistrates may sit alone. Magistrates are appointed by the lord chancellor (in Lancashire by the chancellor of the duchy). There are special juvenile and domestic courts. London has had stipendiary magistrates since the 18th century, as well as lay magistrates with narrowly limited powers. By the mid-1960s their work was being integrated to follow more closely the provincial pattern.

In Scotland four classes of lower courts (justice of the peace courts, burgh and police courts and the court of the baillie of the river and firth of Clyde) try certain summary common-law and certain statutory offenses (*see SCOTS LAW*).

See also COURT: England.

See L. R. Jones, Magistrates' Courts (1953).

(J. E. ML.)

MAGNA CARTA, the great charter of English liberties granted by King John in 1215 under threat of civil war. It was reissued with omissions and alterations in 1216 and again with further changes in 1217. It was also reissued by King Henry III in 1225, after he had been declared of age by the pope. It is this Great charter of 9 Henry III and not its prototype of 1215 that is the Magna Carta of English law and history. This is the document that King Edward I "inspected" in 1297 and had enrolled on his new series of statute rolls. It is this *inspeximus* by Edward I of the Great charter of 9 Henry III that has been printed ever since as the first of English statutes. It is this document that Sir Edward Coke expounded in his famous account of Magna Carta. Whether the name Magna Carta itself was adopted under official instruction or was used casually at first to distinguish between the more inclusive grant covering a wide range of concessions and the charter of liberties touching the forest first granted in 1217 is of little moment. Thirteenth-century Englishmen regarded these two documents, the Great charter and the Forest charter, as together setting out in legal form the contract between king and people that had been won, and might well have to be preserved, by force of arms.

The Origin of the Great Charter.—As the conqueror of England, William I had secured for himself and his immediate successors a position of unprecedented power. He had been able to dominate not only the country he had conquered but the barons who had helped him win it and the ecclesiastics who served the English church. He had forced the pope to be content with indirect control over the church in a land which the papacy hitherto had regarded as bound by the closest ties to Rome. The Conqueror's son Henry I, whose accession (1100) was challenged by his eldest brother, Robert, duke of Normandy, felt himself bound to make, to both his clerical and lay baronage, concessions and promises that were expressed in the most solemn form of document known to contemporary law and practice, a charter sealed with the king's great seal. This was Henry's coronation charter. His successor, Stephen (1135), whose hold on the throne was threatened by Henry I's daughter Matilda, again issued a solemn charter (1136) with even more generous promises of good government in church and state. Matilda's son Henry II, who as duke of Aquitaine as well as king of England might well need from his tenants in chief much more service abroad, also began his reign (1154) by issuing a solemn charter promising to restore and confirm the liberties and free customs which King Henry, his grandfather, had granted "to God and holy church and all his earls, barons and all his men." There developed, in fact, through the 12th century, a continuous tradition that the king's coronation oath should be strengthened by written promises sealed with the king's

seal. But as the volume of common law increased during this period, and in particular during Henry II's reign, no converse definition had been secured in regard to the financial liabilities of the baronage to the crown, and there had been no definition of the rights of justice over their own men which the baronage had inherited from the Anglo-Saxon or from their own feudal past. As the Angevin administration became ever more firmly established with learned judges, able financiers and trained clerks in its service, the baronage as a whole became ever more conscious of the weakness of its position in the face of the agents of the crown.

The increased taxation of Richard I's reign, resulting from his crusade, his ransom and his war with France, would in any case have made difficulties for his successor. John's position was made even weaker because of the rival claim to the throne of his nephew Arthur of Brittany and the determination of Philip II of France to end the English hold on Normandy. John did not issue a general charter to his barons at the beginning of his reign (1199). At Northampton, however, Hubert Walter, archbishop of Canterbury, William Marshal and Geoffrey Fitzpeter, the justiciar, had summoned to meet them there all those great men of whose loyalty they were not assured, and had promised, on behalf of the king who was still in France, that he would render to each his rights if they would keep faith and peace with him. As early in the reign as 1201, the English earls were refusing to cross the sea in the king's service unless he first promised them "their rights," and in 1205, in face of a threat of invasion from France, the king was compelled to swear that he would preserve the rights of the kingdom unharmed. After the loss of Normandy in 1204, backing for the king's foreign policy had to be found from English resources alone and a new urgency in the collection of money due to the crown soon began to be felt. The quarrel with Pope Innocent III over the election of Stephen Langton to the see of Canterbury resulted in the interdict (1208–13) and left the English church defenseless in the face of John's financial demands. The excommunication of the king in 1209 deprived him of some of his ablest administrators. It is not surprising to find that when peace with the church was made and a leader of the calibre of Stephen Langton became in fact as well as in name archbishop of Canterbury, he directed current baronial unrest into the demand for a solemn grant of liberties from the king to be founded on the coronation charter of John's great-grandfather, King Henry I.

THE GREAT CHARTER OF 1215

A detailed account of the momentous happenings in the months immediately preceding the sealing of the charter has been preserved by the historians of St. Albans abbey. Many, although not all, of the documents issued immediately before the charter have survived either in the original or in office transcripts to indicate the course of events. It is clear that the king already had realized that he must give way so far as to grant free election to ecclesiastical office and to meet the barons' general demands. It is equally clear that the archbishop and the most influential earl, William Marshal, earl of Pembroke, had considerable difficulty in bringing the extremists among the baronage to a frame of mind in which they would negotiate. They wanted to fight, although it is not clear what use they would have made of a military victory in 1215. The document known as the Articles of the Barons was at last agreed upon and to it the king's great seal was set. It became the text from which the final draft of the charter was hammered out in the discussions at Runnymede in June. The charter was a compromise, but it also contained important clauses designed to bring about reforms in judicial and local administration. They can hardly have been of major interest at that moment either to the king or to the barons, and their insertion in the charter can probably be ascribed to the determination of the archbishop and the advice of the experienced judges and administrators with whom he had been in close touch since the excommunication of 1209.

For ease of reference this charter, written continuously like any deed of conveyance, has traditionally been discussed as consisting of a preamble and 63 clauses. The precise interpretation of each clause has been a matter of controversy among historians.

the following brief summary the arabic numbers in parentheses indicate the traditional number of the clause in the charter of 1215:

I. The church to be free and have the right of free election (1, 63).

II. Statements of feudal law of particular concern to tenants in chief of the crown. Inheritance and the amount of relief due from an heir (2, 3). Wardship, its profits and duties (3, 4, 37, 46). Marriage of heirs to be without disparagement (6) and the position and remarriage of widows (7, 8). Debt: protecting the debtor and his heirs from crown agents and Jews (9-11); procedure when the debtor has left a will (26) or died intestate (27). Financial aid due to the crown (12) and rules for the summons and conduct of the feudal great council for determining any additional aid (14).

III. Clauses which directly concern subtenants and free men rather than, or as well as, tenants in chief. All the customs and liberties which the king has promised to observe toward his men all other men shall observe toward theirs (60). The same restrictions in taking financial help from their men shall bind the tenants in chief as they bind the king (15). No one is to be distrained to do more service for a knight's fee or other free tenement than he owes (16). Regulation of castle guard service (29). "No freeman shall be taken or imprisoned, or disseised, or outlawed, or exiled, or in any way destroyed, nor will we go upon him, nor will we send upon him, except by the lawful judgment of his peers or by the law of the land" (39). "To no one will we sell, deny, or delay right or justice" (40). All persons are to be free to come and go and stay in the land in time of peace except outlaws, prisoners and enemy aliens (42).

IV. Clauses referring to towns, trade and merchants. The city of London and the crown (12, 13); other cities, boroughs, towns and ports (13). Regulation of weights and measures for wine, ale, corn and cloth (35). Kydeils, that is, traps for fish which might impede traffic, to be removed except on the coast (33). All merchants to be free to come and go and stay in the land to buy and sell without unreasonable tolls and in accordance with ancient custom, except in time of war. Then merchants of an enemy country shall be held until the king or his justiciar learns how English merchants are treated in the enemy's land. If English merchants are safe there the foreign enemy merchants shall be safe (41).

V. Clauses touching the reform of justice and the law. Common pleas are not to follow the court, but to be held in some certain place (17). Recognitions of *novel disseisin*, *mort d'ancestor*, and *darrein presentment* are only to be held in their own shires: two justices to be sent to each shire four times a year, who together with four knights of each shire chosen by the shire court shall take these assizes in the shire court on the day and in the place of its meeting. If they cannot be taken on that day enough knights and free tenants of those present shall remain, through whom the business adequately can be carried out (18, 19). Amercements (fines) for slight offenses shall be in accordance with the measure of the offense. Amercements for serious offenses shall not be so heavy as to deprive anyone of his means of livelihood. Amercements to be assessed by honest men of the neighborhood (20). Earls and barons are to be amerced by their peers according to the measure of their offense (21). Clerks are to be amerced according to the measure of their offense and their lay tenement, not according to the amount of their ecclesiastical benefice (22). The lands of those convicted of felony shall be held by the king for a year and a day only and then shall return to the lord of the fee (32). The writ called *praecipe* in future shall not be issued for anyone touching any tenement whereby a free man may lose his court (34). Nothing in future shall be given or taken for a writ of enquiry touching life or limb, but it shall be granted freely and not denied (36). No bailiff on his own bare word without credible witnesses is to send a man to the ordeal (38). No one is to be taken or imprisoned on account of a woman's appeal touching the death of anyone other than her husband (54). Clauses 39 and 40 (see III above) also can be regarded as falling under this heading.

VI. Clauses to control the behaviour of royal officials, particu-

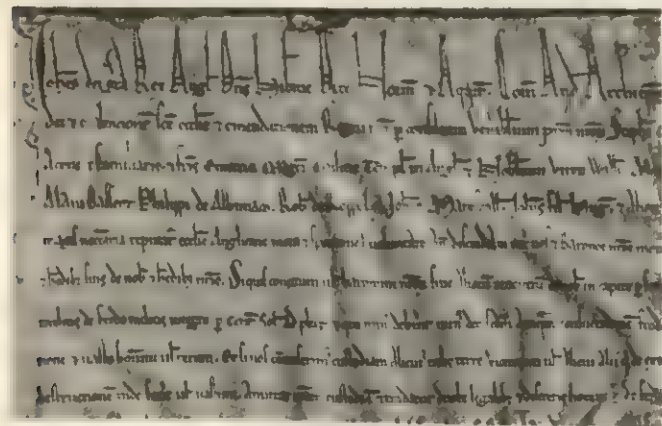

larly those of local government. No town or individual shall be forced to make bridges or maintain river banks except those who ought to do it by ancient custom and by right (23). No sheriff, constable, coroner or other bailiff shall hold pleas of the crown (24). All counties, hundreds, wapentakes and ridings shall be at their old farms without any increment, except in the king's demesne manors (25). No constable or other royal officer shall take anyone's corn or other chattels without making immediate payment, unless the seller is willing (28). No sheriff or any other royal officer shall take any free man's horses or carts for carriage duty except with the owner's consent (30). Neither the king nor any of his officers shall take another's wood for castle building or other royal works without the consent of the owner (31). The king will not appoint any judges, constables, sheriffs or bailiffs, except such as know the law of the land and are willing to keep it well (45).

VII. Forest clauses. Men who live outside the forest shall not come before the forest justices on the general summons unless they are concerned as parties or sureties in a plea (44). All forests made by King John and all river banks put in defense in his time shall immediately be restored to their former state (47). Twelve knights elected in the shire court shall inquire at once in every county about evil customs touching forests and warrens and their keepers and immediately after the inquiry all evil customs shall be abolished, provided that the king is first informed (48). The king shall have the crusaders' respite allowed him in regard to the possible disafforestation made by Henry II or Richard I (52).

VIII. Clauses concerning political matters and correcting temporary abuses. All hostages and charters taken from Englishmen are to be returned (49). Welsh grievances are to be considered and justice done in cases of Welshmen disseised without the lawful judgment of their peers. Disseisins of this nature made by Henry II and Richard I are to be investigated (56, 57). Welsh hostages and charters are to be restored (58). The complaints of Alexander, king of Scots, shall be dealt with in the king's court by judgment of his peers, like those of the king's other barons (59). Certain named foreign mercenaries and their followers are to be removed from their offices (50). All foreign mercenaries are to be sent out of the land (51). Disseisins by the king without the lawful judgment of the tenant's peers, or disseisins similarly done by Henry II or Richard I, are to be restored and disputes in regard to them settled by the judgment of the 25 barons chosen to be guardians of the charter together with the archbishop of Canterbury. All financial agreements made unjustly with the king are to be dealt with in the same way. The king is to have the crusaders' respite (52-55).

IX. The form of security for the maintenance of the charter. The barons shall choose 25 of their number to be guardians of the charter. If the king or any of his officers shall do anything to infringe its terms the offense shall be notified to 4 of the 25, who shall go to the king or his justiciar to ask that the matter be put right. If by 40 days this shall not be done, the 4 barons shall refer the question to the whole body of the 25, who, together with the community of the whole realm, "shall distrain and trouble us in all possible ways by taking our castles, lands, and possessions." When redress has been forced upon the king former relations with him shall be resumed. Anyone who wishes can swear to obey the 25. The king shall enforce the oath on anyone who refuses to take it. On the death of one of the 25 the survivors shall appoint his successor. Disputed matters shall be settled by a majority vote. The king will not directly or indirectly do anything whereby these concessions may be revoked or diminished (61).

Much explosive material is set out in this Magna Carta sealed by King John "in the meadow called Ronimed between Windsor and Staines on the fifteenth day of June in the seventeenth year of our reign." The remarkable fact is not that war broke out between the king and his barons in the following months but that the king had ever been brought to agree to the sealing of such a document at all. That the king genuinely desired to avoid civil war, that he was prepared to accede to reasonable demands for a

B. J. HARROP, LINCOLN, ENG

(TOP) REPRODUCTION OF MAGNA CARTA FROM THE ORIGINAL IN LINCOLN CATHEDRAL: (BOTTOM LEFT) OPENING OF THE PREAMBLE TO THE CHARTER WHICH BEGINS: "JOHANNES DEI GRATIA, REX ANGLIE, DOMINUS HYBERNIE, DUX NORMANNIE ET ACQUITANIE." TRANSLATION: "JOHN, BY THE GRACE OF GOD, KING OF ENGLAND, LORD OF IRELAND, DUKE OF NORMANDY AND ACQUITAINNE"; (BOTTOM RIGHT) THE 39TH CLAUSE OF THE CHARTER, WHICH BEGINS "NULLE LIBER HOMO CAPIATUR VEL IMPRISONETUR . . ." TRANSLATION: "NO FREE MAN SHALL BE TAKEN OR IMPRISONED . . ."

statement of feudal law, that he had a basic desire to give good government to his subjects is strikingly shown by his submission to the humiliating conditions of these final clauses which, in effect, authorized his subjects to declare war on their king. Although it

is profitless to speculate long about the origin of this "form of security," it is perhaps permissible to wonder whether it was the work of the barons themselves or of their adviser, Stephen Langton. There is a specious reasonableness about its eminently

practical rules that suggests the speculations of someone not fully in touch with the daily practice of the king's court. That there was much negotiation and argument, that the king's side was dissatisfied with the choice of the 25 and felt the need of other *observatores et obsecutores* ("guardians") to see that the barons on their side kept their word is evident from one version of Matthew Paris' chronicle. Nevertheless, it is immaterial whether this "form of security" was the work of Stephen Langton feeling his way toward a limited monarchy or of the barons expressing their feudal right of formal defiance after failure to get redress for a contract broken by their lord. This clause is of interest because it illustrates the way men were talking and thinking about kingship in 1215, but since it is omitted from all later versions of the charter, it is not from this clause that the magic of Magna Carta comes.

THE REISSUES OF 1216 AND 1217

King John died on Oct. 18/19, 1216, while Louis of France (afterward Louis VIII), supported by rebellious English barons, was trying to gain control of the land. Almost the first act of the council of the young king Henry III was to reissue the charter on Nov. 12 in the hope of recalling men to their allegiance to the rightful king. The charter of 1216 was a considerably shorter document than its predecessor—42 clauses against 63 in 1215—for the council omitted clauses dealing with purely temporary and political matters (sections VIII and IX above) as well as those which might limit its own power to raise money or forces to carry on the war. The church, while keeping a general promise of freedom, lost its specific guarantee of free election to office. But even in this moment of danger the council did not forget one main purpose of the charter, to provide a definitive statement of feudal law. It tried by individual verbal changes to clarify points in doubt, such as the position of a widow in relation to her dower and her residence and the precise year at which an heir should attain his majority, namely 21. Instead of the "form of security," the council stated that all omissions were postponed for future consideration. They were never replaced.

When the charter was reissued for the second time in the autumn of 1217 the council had reconsidered it clause by clause. They made further verbal changes for the sake of clarity and accuracy. They modified the promise of assize justices visiting every shire four times a year to the more practical suggestion of an annual visit and reserved difficult cases to be heard by the bench judges. The widow's position was yet more clearly set out. The vexed question of scutage, omitted altogether in 1216, was in 1217 glossed over by a promise to revert to the practice of Henry II. That the council in 1217 still wished to make the charter an authoritative statement of English law and practice is shown by the inclusion of three new clauses each dealing with a burning question: the possibility of a man giving away so much of his land that he could not perform his service to his lord from the remainder (39); the conduct of the shire court and view of frankpledge (42); and a first attempt at mortmain legislation (43). But the omission of section VII above and the expansion of these forest clauses into the separate Forest charter show that the council was beginning to realize that a full statement of the law on a single important subject cannot be compressed into a general charter of liberties however long.

HISTORICAL IMPORTANCE

The declaration of the pope in 1223 that Henry III was of age to make valid grants was followed in 1225 by the issue of the Great charter of 9 Henry III. Only minor changes were made in the document as it had stood in 1217. The king stated that he had made the grant of his own free will and in return for a financial grant in aid. It would seem probable that as early as 1225 it had been realized that the effort to make the charter an up-to-date code of law that could be developed to suit changing conditions was impracticable. The Great charter was becoming a symbol, a battle cry against oppression, not a sober statement of the common law. But, as the generations came and passed, a document which had been read so many times in the shire courts

up and down the land under orders from the king was bound to provide common speech with memorable phrases to be reproduced from time to time in courts of law. Whenever liberty seemed in danger, men spoke of the charter as their defense. It follows that the great and beneficent influence of Magna Carta in England and in every land across the sea in which Englishmen have settled has come not from the detailed expression of the feudal relationship between lord and man but from the more general clauses in which every generation could see its own protection. In England the Petition of Right of 1628 and the Habeas Corpus act of 1679 look directly back to clause 39 of the 1215 charter (see III above). When in 17th-century America individual states were shaping their own fundamental laws, the very words of Magna Carta were worked into them. The fundamental rights of man embodied in the federal constitution of 1787 have echoes of the charter. Even as late as 1868 the 14th amendment can trace its ancestry to Magna Carta. The word "charter" implies a grant in favour of the recipient, but it is Magna Carta and its centuries of history that have made the word inseparable from the language of freedom.

The essential virtue of Magna Carta, which transformed it into law comparable by a modern scholar to the Twelve Tables of ancient Rome, lies not in any individual clause or group of clauses but in the solemn circumstances of its first granting and the comprehensive nature of that grant. Hence the Magna Carta that the common man remembers is the Magna Carta of King John and the date that always has been commemorated as its granting is the year 1215. That many clauses were omitted from the charter as it finally appeared on the statute rolls, that new ones had been inserted and some original clauses redrafted has made no difference in the national memory of this venerable grant. Nevertheless, in trying to estimate the influence of the charter on constitutional development in England and overseas, it should be borne in mind that, while the drama has never faded from the field of Runnymede, the actual phrases studied by those who fought oppression in 17th-century England or 18th-century America came immediately from the charter of 9 Henry III.

Surviving Manuscripts.—There still exist four originals of the charter of 1215, two of them in the cathedral churches in which they were originally deposited, Lincoln and Salisbury, the other two in the British museum. The Lincoln charter was considered the most nearly perfect and was reproduced in the Statutes of the Realm in 1810. Lincoln also possesses the Forest charter of 1225, Durham possesses the 1216, 1217 and 1225 Great charter as well as the Forest charter of 1217 and of 1225. The Wiltshire copy of the 1225 charter was deposited at Lacock abbey and survives.

MAGNA GRAECIA ("great Greece": Gr. *megale Hellas*), the name given (first, apparently, in the 6th century B.C.) to the group of Greek cities along the coast of the "toe" of southern Italy (or, more strictly, to those between Tarentum [Taranto] and Locri, along the east coast); the people were known in Greece as Italiotes, to the Romans as Graeci. The interior remained in the hands of the Bruttii, the native mountaineers, after whom the district was named in Roman times (Bruttii, Gr. Brettia).

There was trade between Greece and Italy in the Mycenaean

period (see GREECE: *History*), and there may be a reference to the copper trade in Homer (*Odyssey*, i, 184). In historical times the first Greeks to settle in the west were the Euboeans from Chalcis and Eretria, who founded Cumae (q.v.) in Campania c. 750 B.C. After this the Chalcidians went onward to Sicily, though they founded Rhegium (Reggio di Calabria) c. 720 B.C. at the request of their colonists at Zancle (Messina). Italy was colonized largely by the states of the Corinthian gulf—Sybaris (c. 720) and Crotona (c. 710) were Achaean settlements; Locri Epizephyrii (c. 680), Locrian. The only Dorian colonies in Italy were Tarentum, founded by Spartans c. 700, and its daughter cities Callipolis (Gallipoli), Hydruntum (Otranto) and later Heraclea (q.v.; 433). Ionian Greeks fleeing from foreign invasions founded Siris c. 650 and later Elea (Velia; c. 540).

The Italian colonies, planted among friendly peoples, grew much more rapidly than the Sicilian Greek states, which had to contend against Carthage. After the Achaean cities had founded Metapontum (c. 700) as a counterpoise to the Dorian Tarentum, there was little strife among the Italiotes. An amphictyonic league, meeting at the temple of Hera on the Lacinian promontory (Capo Colonne), fostered a feeling of unity. The Pythagorean and Eleatic systems of philosophy had their chief seat in Magna Graecia. Italiote competitors in the Olympic games included the famous Milo of Crotona, and in the 6th century the physicians of Crotona (especially Democedes) were reputed the best in Greece. Strife recommenced in the late 6th century; an Achaean coalition destroyed Siris c. 540, and in 510 the Crotoniates defeated the Sybarites and totally destroyed their city. The Athenian-sponsored Panhellenic colony at Thurii (443) was intended to replace Sybaris. Magna Graecia (unlike Sicily) took little part in the Peloponnesian War; Locri was strongly anti-Athenian but Rhegium, though the headquarters of the Athenian force in 427, remained neutral in 415. Henceforward foreign enemies pressed heavily on the Greek cities. The Lucanians and Bruttians on the north captured one town after another. Dionysius the Elder of Syracuse attacked from the south; after he defeated the Crotoniate league and destroyed Caulonia (389), Tarentum remained the only powerful city. Repeated expeditions from Sparta and Epirus tried in vain to prop up the decaying Greek states against the Lucanians and Bruttians, and when in 282 the Romans appeared in the Tarentine gulf the end was close at hand. The aid that Pyrrhus (q.v.) brought did little good to the Tarentines, and his final departure in 274 left them defenseless. Malaria increased as population diminished. Many of the cities disappeared, and hardly any were of great importance under the Roman empire, though some, like Tarentum, maintained their existence until modern times.

MAGNARD, (LUCIEN DENIS GABRIEL) ALBÉRIC (1865–1914), French composer of symphonic music and operas. Born at Paris on June 9, 1865, he studied at the Paris conservatoire under Massenet and later privately under Vincent d'Indy. His four symphonies, written between 1894 and 1913, are remarkable for their lyrical qualities. His operas, *Yolande* (1892), *Bérénice* (1911) and *Guercoeur* (first complete production in 1931, with reconstruction by Guy Ropartz), for which he wrote the librettos himself, use the leitmotiv technique. He spent most of his life at Baron, near Senlis, where on Sept. 3, 1914, he perished when his house was burned by invading German troops. His work had little success in its day but was revived after World War I, when for a short time it had a considerable influence.

See G. Carraud, *La Vie . . . d'Albéric Magnard* (1921). (E. L.R.)

MAGNASCO, ALESSANDRO (called LISSANDRINO) (1667–1749), Italian painter distinguished for his genre painting with small figures, was born at Genoa, where he studied under his father, Stefano. He afterward worked in Milan with an obscure Venetian painter, Filippo Abbiati. He began as a portrait painter, but only one self-portrait is known. His later scenes were from the lives of monks, nuns, gypsies or bandits, frequently set in romantic landscapes. These are extremely loosely painted in a

dramatic, almost ecstatic manner, influenced by P. Morazzone and reminiscent of Salvator Rosa, Jacques Callot and M. Cerquozzi. Very few are dated or datable.

Some time between 1693 and 1698 he met Sebastiano Ricci, through whom he exercised a marked influence on Venetian 18th-century painting. Later he moved to Florence, where he found employment at the court of the grand duke, and after traveling about Tuscany and Emilia he returned to Milan, where he remained from 1711 until 1735. He then returned to Genoa, where he died on March 12, 1749.

Magnasco was exceedingly prolific both as a painter and a draftsman and occasionally collaborated with C. Spera, C. Tavella, M. Ricci and Perugini, inserting figures in their landscapes. Though he had no pupils, he had several imitators, notably the Neapolitan Ciccio and the Milanese Coppa.

See B. Geiger, *Saggio d'un Catalogo delle Pitture di Alessandro Magnasco* (1945) and A. Morassi, *Catalogue of the Mostra di Magnasco* (1949), both have full bibliographies. (F. J. B. W.)

MAGNATE, a noble, a man in high position, by birth, wealth or other qualities. The term seems originally to have been used to describe the chiefs of the barbarian tribes who invaded Europe in the dark ages. Later it was specifically applied to the Hungarian nobility, *maiores natu et dignitate, seniores*. The upper house in Hungary, the *Főrendiház*, was called the house of magnates, and until its disappearance at the end of World War II, it was the only second chamber in Europe, apart from the British house of lords, to preserve a strong hereditary element. The popular application of the term to a wealthy man nowadays is almost invariably satirical. (S. B.-R. P.)

MAGNENTIUS (FLAVIUS MAGNUS MAGNENTIUS), usurping Roman emperor A.D. 350–353, was a pagan and a distinguished soldier of German descent. He assumed the purple at Autun on Jan. 18, 350, and, after having the emperor Constans (q.v.) murdered, he reigned over the west. In June he overthrew Nepotianus, who had proclaimed himself emperor at Rome. He failed to win recognition from Constantius II (q.v.), but formed an alliance with Vetranio, commander of the Danubian troops, who had proclaimed himself emperor on March 1, 350. But Constantius easily overthrew Vetranio. Early in 351 Magnentius appointed his brother Decentius as Caesar and sent him to the Rhine frontier where Constantius had caused the Germans to undertake an offensive so as to divide Magnentius' forces.

But Magnentius repulsed the emperor at Atrians in 351 and advanced to Pannonia. Constantius, however, rallied and won the great battle of Mursa (q.v.) on Sept. 28, 351. In 352 Constantius invaded Italy. Magnentius fell back on Gaul and committed suicide on Aug. 11, 353. (E. A. T.)

MAGNES, JUDAH LEON (1877–1948), U.S. rabbi, founder and first president of the Hebrew university in Jerusalem, was born in San Francisco, Calif., on July 5, 1877. Educated at the University of Cincinnati, O., and Hebrew Union college, Cincinnati, he became a rabbi in 1900 and continued his studies in Germany. After a year as librarian at Hebrew Union college he went to New York where he was rabbi of a Reform synagogue in Brooklyn (1904–06) and then of Temple Emanuel on Fifth avenue (1906–10), which he left after conflict with the trustees. He then devoted himself to forming the various Jewish groups in the city into one community. During World War I he worked for the relief of Jews in eastern Europe. He left the United States in 1922 and made Palestine his home. In 1925 he founded the Hebrew university, becoming its first chancellor and then its president (1935). During World War II, in which he supported the Allied cause after a bitter internal struggle, having been previously a pacifist, he founded Ihud ("Unity"), a society working to form a commonwealth of Jews and Arabs in an undivided Palestine. Magnes died in New York on Oct. 27, 1948.

See N. Bentwich, *For Zion's Sake* (1954).

MAGNESIA, in ancient geography a district in eastern Thessaly (q.v.) lying between the Vale of Tempe and the Gulf of Pagasae. The modern Greek *nomos* of Magnisia comprises the southern half of ancient Magnesia with the addition of much of ancient Achaia-Phthiotis round the Pagasae gulf; its capital is

(S. H. B.)

Volos. Magnesia was also the name of two Greek cities in Asia Minor.

MAGNESIA AD MAEANDRUM, an inland city of Ionia, situated on a small tributary of the Maeander (Buyuk Menderes) river about 12 mi. S.E. of Ephesus. According to Strabo, it was founded by some Thessalian Magnetes, who had collected fellow settlers from Crete en route. Accounted an Aeolian city, it was never, despite its early prosperity, included in the Ionian league. Destroyed in the Cimmerian invasion of c. 650 B.C., it slowly recovered and became the residence of Oroetes, the Persian satrap, who murdered Polycrates of Samos there about 522, and later of the exiled Themistocles, who received it, with other towns, from Artaxerxes I and issued some Magnesian coins about 460. Too far inland to enter the Athenian empire, it was occupied by the Spartan Thibron in 399 and transplanted to a more defensible site among the eastern foothills of Mt. Thorax, around the existing shrine of Artemis Leukophryene. The new city assumed a monumental form about 200 B.C. It continued to flourish under the kings of Pergamum and the Roman republic, and produced Hegesias, founder of the rhetorical school called "Asiatic." It resisted Mithradates VI of Pontus in 87 B.C., and was rewarded with political freedom by Sulla. It appears to have declined under the empire, though on a rare bronze coin of the time of Gordian III (A.D. 238-244) it still calls itself the seventh city of Asia.

The famous temple of Artemis Leukophryene was rebuilt about 200 B.C., following its old roughly east-west orientation. The building, rather strangely, faced westward, and the great altar to its west, yet more strangely, turned its back on it and roughly faced the agora. But the agora in its turn, though contemporary, ignored the orientation of temple and altar and was laid out as a long rectangle running due north and south. The rest of the city formed a grid, made out of insulae (blocks) each one-sixth of the agora in size. A. von Gerkan restored the altar, rather questionably, to copy the Great Altar of Pergamum. The main temple, designed by the famous Hermogenes, mentor of Vitruvius (q.v.), was Ionic. The carved frieze of the main order, unusual for Asia, shows its late date; and notable features are the doors inside its pediments and the floral acroteria with central grotesques. Apart from the agora, the rest of the city, largely defaced by a modern railway, is more ordinary. It includes a fairly perfect theatre and the shell of a large gymnasium.

The frieze of the temple was mostly carried to Paris by C. Texier in 1843. Further excavations of both temple and city were conducted between 1891 and 1893 by K. Humann, R. Heyne and O. Kern.

MAGNESIA AD SIPYLUM (modern Manisa), a city of Lydia, just south of the Hermus (Gediz) river. Though lying in a rich district and going back to the 5th century B.C., it is of little importance except for the battle of winter 190/189 B.C., described in Livy, xxxvii, when the Romans under Lucius Scipio decisively defeated Antiochus III and threw him back permanently to the other side of the Taurus range. It suffered severely from earthquakes, notably in A.D. 17, and has left rather scanty remains.

BIBLIOGRAPHY.—O. Kern, *Die Inschriften von Magnesia* (1900); K. Humann, *Magnesia am Mäander* (1904); A. von Gerkan, *Der Altar des Artemistempels in Magnesia am Mäander* (1929). (Wl. H. P.)

MAGNESITE, one of the calcite group of rhombohedral carbonate minerals, consisting of magnesium carbonate, is a principal source of magnesium. It is mined in Austria, Czechoslovakia, Yugoslavia, Greece, the Ural mountains, India, Manchuria, Australia, California, Nevada and Washington. It is used for making refractory firebricks for lining steel furnaces; for magnesium oxychloride (Sorel) cement (q.v.), used mainly in flooring; for preparing magnesium chemicals, including those used as a component of fertilizer; and as a catalyst and filler in making synthetic rubber. The formula of magnesite is $MgCO_3$. Extensive substitution of iron, as well as lesser amounts of calcium and manganese, may occur in place of magnesium. It is rarely found in good single crystals, occurring either as crystalline aggregates or as earthy to compact masses. When pure it is white, with a hardness of 3.75 to 4.25 depending on direction, and a specific gravity of 3.0. Although found in some beds deposited from saline lakes, it more commonly

occurs either as a replacement of limestones and dolomites or as a breakdown product of serpentine attacked by hot carbonate solutions. In the latter, it usually contains admixed opaline silica and magnesium silicates.

(D. L. G.)

MAGNESIUM, a metallic chemical element, symbol Mg, of silvery white appearance, is the world's lightest structural metal. Because magnesium in its pure state is highly active, man's first knowledge of it came from its compounds. The sulfate, Epsom salts, was isolated in 1695 by the English botanist Nehemiah Grew, while in 1707 M. B. Valentine prepared the carbonate, *magnesia alba*, from the mother liquors obtained in the manufacture of nitre. The oxide, *magnesia*, was confused with lime until 1755, when Joseph Black showed that the two substances were entirely different. Sir Humphry Davy in 1808 produced the amalgams of magnesium and isolated the metal by distilling off the mercury. In 1828 the metal was prepared (in a state approximating to purity) by A. Bussy who fused the anhydrous chloride with potassium.

Michael Faraday in 1833 was the first to succeed in producing metallic magnesium by electrolysis of molten magnesium chloride, using a voltaic cell. Robert Bunsen achieved the same result in 1852, his electrolytic cell corresponding in construction to the principle of the modern cell. In France, H. Sainte Claire Deville and H. Caron in 1857 accomplished the reduction of anhydrous magnesium chloride with sodium. In 1886 the electrolytic process was further developed by F. Fischer and R. Graetzel in Germany. Electrolytic methods entirely superseded the older ones until about 1941 when the carbothermic and ferrosilicon techniques, employing a thermal process, came into commercial use.

OCCURRENCE AND PRODUCTION

It is estimated that magnesium forms about 2.1% of the earth's crust, being the third most abundant of the industrial metals. It is found widely distributed in nature in a variety of forms. The carbonate, oxide and chloride are the ones most widely used and occur as dolomite, magnesite, brucite and carnallite. Magnesium also occurs in silicate minerals of which the most important are olivine, serpentine and asbestos. Although the silicate minerals are of world-wide occurrence, they are not suitable raw materials for magnesium metal manufacture because of the difficulties in separation.

Magnesium is found as chloride in sea water and in certain deep-well brines, such as those of Michigan. Magnesite, $MgCO_3$, is the most important solid source of magnesium and is widely distributed throughout the world, the largest deposits being in Austria, the U.S.S.R., Greece, Czechoslovakia, Manchuria and the Pacific coast of North America. Dolomite, or magnesian limestone, $MgCO_3 \cdot CaCO_3$, is also widely distributed, there being abundant deposits in the United Kingdom, Austria, Hungary, Germany, Switzerland, Italy, Spain and the United States. Carnallite, $MgCl_2 \cdot KCl \cdot 6H_2O$, forms a layer of the great salt beds at Stassfurt, Ger., and provided the raw material for the first electrolytic production of magnesium on a commercial basis, although it is not now an important raw material. Large deposits of the hydroxide, brucite, $Mg(OH)_2$, are found in Quebec and in Nevada.

Magnesium Minerals

Name	Nominal formula	% Mg contained
Magnesite	$MgCO_3$	28.7
Dolomite	$MgCO_3 \cdot CaCO_3$	13.8
Brucite	$Mg(OH)_2$	41.6
Serpentine	$3MgO \cdot 2SiO_2 \cdot 2H_2O$	25.9
Olivine	$(MgFe)_2 SiO_4$	28.4
Talc	$3MgO \cdot 4SiO_2 \cdot H_2O$	20.7-26.9

Other magnesium minerals found in salt deposits from evaporation of ancient seas include:

Carnallite	$MgCl_2 \cdot KCl \cdot 6H_2O$
Schoenite	$MgSO_4 \cdot K_2SO_4 \cdot 6H_2O$
Polyhalite	$MgSO_4 \cdot 2CaSO_4 \cdot K_2SO_4 \cdot 2H_2O$
Kieserite	$MgSO_4 \cdot H_2O$
Epsomite	$MgSO_4 \cdot 7H_2O$
Kainite	$MgSO_4 \cdot KCl \cdot 3H_2O$
Langbeinite	$2MgSO_4 \cdot K_2SO_4$

Although brucite is richer in magnesium than any other ore, it is extremely local in occurrence.

Leading producers of primary magnesium in the second half of the 20th century were the U.S., U.S.S.R., Norway, Canada, Italy, the United Kingdom, France and Japan; of magnesite, the U.S.S.R., Austria, China, Czechoslovakia, the U.S. and Yugoslavia.

Two chief methods were in use in the second half of the 20th century for the commercial production of magnesium, one electrolytic, the other thermal, the former accounting for the bulk of industrial production. In Germany, where the magnesium industry was first developed on a large scale, the process was based on the electrolysis of molten magnesium chloride, a by-product from the potash and carnallite operations at Stassfurt. Magnesium chloride may also be produced from brines, sea water, processed dolomite or by chlorinating magnesite. During World War II the sea water electrolytic process, then (1941) the newest method of producing magnesium, accounted for the bulk of production in the U.S. In this process sea water, which contains about 0.13% magnesium, is pumped into huge settling tanks where it is mixed with lime. The calcium from the lime is exchanged with the magnesium in the sea water which precipitates as insoluble magnesium hydroxide, settles to the bottom of the tank and is filtered off. The magnesium hydroxide is then converted to magnesium chloride by reaction with hydrochloric acid prepared from natural gas and chlorine, $\text{Mg}(\text{OH})_2 + 2\text{HCl} \rightarrow \text{MgCl}_2 + 2\text{H}_2\text{O}$.

After thorough drying, which may be accomplished by means of spray or shelf driers or a combination of the two, the magnesium chloride or cell feed is fed to the electrolytic cells where electricity breaks it down into magnesium metal and chlorine gas, $\text{MgCl}_2 \rightarrow \text{Mg} + \text{Cl}_2$. A typical cell is a large rectangular steel pot which holds the fused salt bath, conducts the current to the internal cathodes and contains approximately 10 tons of molten salts. This stands in a gas-fired refractory brick furnace. The pot and its internal parts act as the cathode while graphite anodes are suspended in the top of the cell. Granular MgCl_2 is continuously fed into the top of the cell except when dipping metal or servicing the cell. The cell bath is a mixture of molten salts held at 700° C. During electrolysis the magnesium metal is liberated at the cathode and rises to the surface of the bath where it is guided by inverted troughs to the metal wells in the front of the cell. Metal of 99.9% purity is dipped out of the cell at 4-hr. intervals and poured into ingot molds.

The thermal process obtains magnesium by the direct reduction of its compounds with suitable reducing agents. In this process the reaction takes place above the boiling point of magnesium, permitting the metal to be separated from the residue by distillation and to be condensed in solid or liquid form.

The Pidgeon ferrosilicon process, an example of the thermal technique, was developed in Canada during 1941. It makes use of ferrosilicon and calcined dolomite which is fed into vacuum retorts, yielding a magnesium vapour which condenses in crystals on a water-cooled sleeve, $2(\text{MgO} \cdot \text{CaO}) + \text{Si} \rightarrow 2\text{Mg}\uparrow + 2\text{CaO} \cdot \text{SiO}_2$ (the iron does not react). The crystals are melted and poured into ingots.

Another thermal method, the carbothermic process, was invented in 1928 in Austria. The process centres around the reduction of magnesium oxide obtained by crushing and calcining magnesite. In the original process, the oxide after being mixed with anthracite was pressed into pellets and charged into electric-arc furnaces where the magnesium vapourized, $\text{MgO} + \text{C} \rightarrow \text{Mg}\uparrow + \text{CO}$. A chilling blast of hydrogen turned the vapour into a highly inflammable magnesium dust. The dust was tableted in a press, fed into retorts and vapourized again, yielding magnesium crystals which in turn were melted and poured into ingots. The process was modified in various ways after it was first designed, including the substitution of natural gas for hydrogen and petroleum coke for anthracite. As a safety measure, the dust is mixed with oil before being loaded into the retorts.

USES

Magnesium was formerly associated in the minds of many people almost exclusively with pyrotechnics, and for many years

the chief production was used for this purpose, as well as for flash ribbon and flash powder in photography and, in wartime, for incendiary bombs. But the increasing emphasis upon weight reduction, both in industrial applications and in consumer goods, gave magnesium an importance far beyond these earlier uses.

Magnesium as a Structural Metal.—The basic crystal structure of magnesium is different from those of iron, copper or aluminum but similar to those of zinc and cadmium. The modulus of elasticity of magnesium and its alloys is relatively low, resulting in a comparatively high capacity for elastic energy absorption. Distortion or slipping in a magnesium crystal can take place on only one series of atomic planes at temperatures up to about 400° F. (about 204° C.). The material therefore tends to harden when worked at room temperature. More atomic planes become available for slipping above 400° F. and the metal can be readily worked without hardening. Magnesium is thus well adapted to hot forming methods. It is quite stable in ordinary inland atmospheres. Brightly polished metal will gradually assume a thin gray film after about one month's exposure. Magnesium is resistant to most alkalis, many organic chemicals, chromic and concentrated hydrofluoric acids, alkali metal fluorides, arsenates, chromates and dichromates. It is attacked to varying degrees by other acids and water solutions of salts. Being high in the electromotive series, magnesium is somewhat more susceptible to galvanic corrosion than other structural metals. Protective atmospheres and fluxes are employed during melting, heat treating and casting of the alloys in order to reduce oxidation and provide clean metal.

Pure magnesium has low structural strength; however alloys have been developed to meet increased property demands, to improve corrosion resistance and to facilitate production and fabrication, the first commercial ones having been placed on the market by the Germans in 1909. The principal constituents of the majority of the commercial alloys of magnesium are aluminum, zinc and manganese. The use of aluminum, the most important alloying constituent of magnesium, imparts hardness and also increases the tensile strength.

Zinc, the second most important alloying element, is usually combined with aluminum to form a ternary alloy and is used chiefly to give a general improvement in properties and to facilitate foundry work. It also improves elongation, especially in the wrought alloys, and is useful for nullifying the detrimental effects of such impurities as iron and nickel, which tend to increase the salt water corrosion rate of magnesium and its alloys.

Manganese, in small proportions, is used in practically all commercial alloys of magnesium because it greatly improves the resistance to salt water corrosion without materially affecting the other properties. Seldom used in a greater proportion than 2.5% it has a small effect on the mechanical properties in the cast state. In the rolled condition, however, manganese increases strength. Improved tensile properties particularly at elevated temperatures can be obtained with magnesium-manganese wrought alloys, especially if small amounts of cerium or calcium have been added to produce fine grain. Magnesium-manganese alloys are of value also because of their good welding properties.

Cerium, calcium, zirconium, cadmium, silver, silicon, beryllium, lithium, thorium and tin are sometimes used as alloying ingredients for special purposes. After World War I, intensive research and development work produced strong, light alloys. The world-wide and rapid development of the aircraft industry played an important part in advancing the use of magnesium alloys for structural purposes, where their unusual advantages were quickly utilized. Perfection of alloys which could be fabricated successfully by casting, extruding, rolling and forging opened up many new fields of use. It possesses special properties which make it particularly desirable for certain types of applications which include exceptional machining qualities and good fatigue resistance and damping capacity under impact stress. The attainment of high standards in pressure die casting technique has presented new spheres of application in the instrument, tool, optical and other industries where designers are often able to substitute a single casting for parts formerly built up from sheet and sections, the die casting being stronger and more rigid but not heavier.

Mechanical Properties.—Pure magnesium in the sand cast state has a tensile strength of 14,000 p.s.i. (7 tons/in.²) and in the extruded condition about 26,000 p.s.i. (13 tons/in.²). The addition of suitable alloying elements doubles these values for cast and wrought alloys. When aluminum is used as an alloying constituent, casting alloys attain their maximum value for tensile strength and elongation in the cast state at approximately 6% aluminum. A substantial further increase in strength is possible by heat treating cast alloys containing 6% to 12% aluminum. Wrought alloys attain maximum strength with approximately 10% aluminum, although alloys with aluminum content as high as this are limited to simple shapes. Those with the lower aluminum contents of 3% to 7% are in more common use.

Aircraft and Spacecraft.—Because of their low specific gravity, magnesium alloys are widely used in the aircraft industry, this being especially true during and after World War II. Typical applications included: housings for camshafts, timing gears, superchargers, oil filters and pumps; landing wheels; forged radial engine crankcases and propeller blades for small planes; floor beams; frames for seats and many small parts such as die-cast instrument housings. Increased use has been made of magnesium sheet in the monocoque or stressed skin type of wing construction and it has been used on a considerable scale for fairings, cowlings and tanks. Magnesium missile sheet has been produced in volume quantities and various alloys have found a number of applications in spacecraft and in guidance systems. Magnesium tooling plate has been used for making memory disks in electronic computer systems.

Transportation.—Although in this field magnesium has found its greatest use in aircraft, there is a growing interest in applying its advantages to other types of transportation, especially in automotive equipment. In Europe, and especially in Germany, magnesium alloys are used in bodies and frames for motor buses and trucks, cast wheels for tramways and buses and in a variety of small parts. In the U.S., magnesium has also been used in the construction of truck bodies and auto-transport trailers. Its use in railroad equipment includes frames for seating, partitions in Pullman cars and instrument panels and housings.

Portable Equipment.—Magnesium is increasingly used for various types of portable goods such as tools, being employed in the housings and handles. Portable platforms and conveyor systems, dockboards, hand trucks, milk crates and similar items are examples of other uses in this field. It is also utilized for office equipment, such as typewriter and adding machine frames, and various types of instrument housings.

Industrial Equipment.—Both because of their light weight and their ability to absorb dynamic energy, magnesium alloys are being used in parts of high-speed and reciprocating machinery. Examples are warp beams, bobbins, spools and knitting bars used in textile machinery. Cast magnesium foundry flasks and molding and core boxes are used in foundries. Because of its high strength-to-weight ratio it is used for industrial gratings and pedestrian bridges.

Consumer Goods.—The use of magnesium in consumer goods of many different types is constantly expanding. This field includes such items as domestic vacuum cleaners, griddles, wheel toys, luggage, lawn mowers, step ladders and photographic and motion-picture cameras. It has also been successfully used in skis, baseball catchers' masks and rowboats.

Miscellaneous.—Magnesium is used as an important alloying element in aluminum alloys, its chief function being to increase the mechanical and corrosion-resisting properties. It also facilitates heat treatment. A growing use of magnesium is as an expendable galvanic anode for the cathodic protection of buried metal structures such as pipe lines, as well as for ship hulls and tanker compartments. Its high position in the electromotive series of metals enables it to perform this function.

Because of its high affinity for oxygen, magnesium is used as a deoxidizer in the manufacture of metals lower in the electromotive series of metals, such as nickel and nickel alloys. Increasing production and use of zirconium, hafnium, uranium and beryllium has resulted in greater demand for magnesium as a reducing agent.

For the various uses of the compounds see *Magnesium Compounds*, below.

PHYSICAL AND CHEMICAL PROPERTIES

The principal physical properties of magnesium, (99.9% pure) are listed in the accompanying table.

Physical Properties of Magnesium

Symbol	Mg
Atomic number	12
Atomic weight	24.312
Atomic volume—c.c./gram-atom	14.0
Crystal structure	Close-packed hexagonal
Electron arrangement in free atoms	1s ² , 2s ² , 2p ⁶ , 3s ²
Mass numbers of the stable isotopes	24 25 26
Relative frequency of the isotopes—%	78.60 10.11 11.29
Melting point (°C.)	650
Boiling point (°C.)	1,103
Density, g./c.c. at 20° C.	1.74
Latent heat of fusion, cal./g.	82.2
Latent heat of vaporization, cal./g.	1,337
Specific heat, cal./g.°C.	0.25 (25°)
Electrical resistivity microhms cm.	3.94 (0° C.)
Modulus of elasticity—lb./sq.in.	6.5×10 ⁶
Modulus of rigidity—lb./sq.in.	2.42×10 ⁶

Chemically, magnesium is a member of group II of the periodic system and has a valence of 2, forming magnesium ion (Mg²⁺). In a finely divided form, it may be ignited in air and burns with an intense white light which is rich in the ultra-violet rays. The products are magnesium oxide (MgO) and the nitride (Mg₃N₂). Larger pieces must be heated above the melting point of the metal before they ignite.

Magnesium is a very strong reducing agent and reacts with most acids liberating hydrogen, $\text{Mg} + 2\text{H}^+ \rightarrow \text{Mg}^{2+} + \text{H}_2$. With nitric acid it reduces both the nitrogen and the hydrogen, $4\text{Mg} + 10\text{HNO}_3 \rightarrow 4\text{Mg}(\text{NO}_3)_2 + \text{NH}_4\text{NO}_3 + 3\text{H}_2\text{O}$ and, $\text{Mg} + 2\text{HNO}_3 \rightarrow \text{Mg}(\text{NO}_3)_2 + \text{H}_2$. It displaces hydrogen from boiling water but is not attacked by alkalis.

MAGNESIUM COMPOUNDS

Preparation and Uses.—The important magnesium compounds, their properties and uses are:

Magnesium oxide, MgO, prepared by calcining magnesite

or by calcining magnesium hydroxide

MgO is a white powder and is sold in various grades: light (caustic burned) magnesia, calcined at about 650° C., and heavy (dead burned) magnesia, calcined at 1,650° C.

Uses: basic refractory brick, high-temperature electrical insulation, oxychloride cement, fertilizer, in rubber and plastics.

Magnesium hydroxide, Mg(OH)₂, a white powder. This compound is the key to recovery of magnesium from sea water. It is precipitated from sea water and Mg-containing brines by the simple addition of milk of lime:

It is used in medicine as an antacid and laxative and in the production of magnesium and the manufacture of other magnesium compounds.

Magnesium carbonate: The commercial product is a basic magnesium carbonate $4\text{MgCO}_3 \cdot \text{Mg}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$ and is made by heating the normal carbonate, obtained by carbonating Mg(OH)₂:

It is also made from dolomite by the Pattinson process. The rock is calcined, hydrated and then treated with carbon dioxide or kiln-gas at several atmospheres pressure. Magnesium bicarbonate goes into solution. After filtration the pressure is released and on boiling, basic magnesium carbonate is precipitated.

It is used as an insulator for boilers and pipes, in table salt to prevent caking, in rubber and ink industries and in pharmaceutical and cosmetic preparations.

Magnesium sulfate, colourless crystals, is sold as Epsom salts, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ and kieserite, $\text{MgSO}_4 \cdot \text{H}_2\text{O}$. Kieserite comes from

the Stassfurt deposits and from British Columbia, Can., while Epsom salts are made by treating olivine with sulfuric acid or by the reaction of magnesium hydroxide, sulfur dioxide and air:

It is a constituent of cements and is used in the leather industry, flotation, medicine, fertilizer and in the paper and textile industries.

Magnesium chloride, colourless deliquescent crystals, prepared by crystallization from brines and bitters, decomposition of carnallite and by the action of HCl on Mg(OH)_2

It is used in magnesium metal production, in oxychloride cements and in textiles. Magnesium oxychloride cements are made by adding a strong solution of magnesium chloride to light (caustic) magnesium oxide. The resulting paste is magnesium oxychloride (approx. $3\text{MgO} \cdot \text{MgCl}_2 \cdot 11\text{H}_2\text{O}$). Fillers such as sand and limestone fines are added. The cement, which can be coloured, takes a high wax polish. It is used for heavy-duty flooring. An increasing use for magnesium oxide and magnesium sulfate is as a fertilizer in Mg-deficient soils, giving increased yields especially with citrus fruits and potatoes.

Organic Compounds.—Important organic compounds of magnesium are known as Grignard reagents (*q.v.*). They are of the composition RMgX (where R = an alkyl or aryl group and X = a halogen). One large-scale use is in the production of silicones:

Magnesium is a constituent of chlorophyll, $\text{C}_{55}\text{H}_{70}\text{MgN}_4\text{O}_6$, and apparently plays a role similar to that of iron in hemoglobin.

Detection.—Magnesium salts can be detected by precipitating magnesium hydroxide with a solution of sodium hydroxide. It is not soluble in an excess of sodium hydroxide, but readily soluble upon addition of a saturated ammonium chloride solution.

Magnesium is determined quantitatively by precipitation as magnesium ammonium phosphate by means of dibasic ammonium phosphate from an ammoniacal solution from which interfering elements have been removed. It is ignited and weighed as magnesium pyrophosphate.

MAGNETIC RECORDING: see TAPE RECORDING, MAGNETIC; PHONOGRAPH.

MAGNETIC STORM, a period of relatively intense fluctuation in the strength of the earth's magnetic field. These storms seem to be associated with major changes in activity on the sun, particularly sunspot variations; however, their origin is incompletely understood. World-wide in their effects, and lasting from a few hours to several days, such geomagnetic disturbances markedly alter the brilliance and latitude of auroral displays (see *AURORA POLARIS*). The shifting intensity of the magnetic field can impair navigation based on forms of magnetic compass and may, in especially severe storms, induce so much current in metal-

lic objects that electric power transmission systems break down or develop serious overloading. Telegraphic and telephone communication also may be interrupted. Increased instability in the ionosphere at these times plays havoc with long-distance radio signals (see *GEOMAGNETISM*). In 1964 J. A. Simpson and co-workers of The University of Chicago reported discovery of a high-energy proton beam that arises from a specifically localized region on the sun. They noted that magnetic storms tend to coincide with the 27-day period of rotation of the sun on its axis. It was suggested that disruption of earth's magnetic field every 27 days by the proton beam may be the basis for these storms.

MAGNETISM, in physics, refers to: (1) ferromagnetism, a property of iron and a few other substances that is characterized by strong attraction of one magnetic body to another; (2) paramagnetism, the quality of relatively weak attraction to magnetized bodies as shown by many substances such as magnesium and tin; and (3) diamagnetism, characteristic of materials such as antimony and bismuth that are repelled by magnetized objects. Ferromagnetism is sometimes considered as an intense form of paramagnetism, and is the most important of these magnetic phenomena for practical application. This discussion is organized as follows:

I. HISTORY

Centuries before the Christian era the Greeks knew that the mineral magnetite (*q.v.*), or lodestone, a magnetic oxide of iron (Fe_3O_4), attracts iron and other pieces of the same mineral. This natural magnet was mentioned by Thales of Miletus (*c.* 500 B.C.); and according to Plato in the *Ion*, Socrates stated that it would support a chain of iron rings, each held to the one above it by magnetic attraction.

The Roman poet and philosopher Lucretius stated in his *De rerum natura*, in the 1st century B.C., that "... iron can be drawn by that stone which the Greeks call Magnet by its native name, because it has its origin in the hereditary bounds of the Magnetes," the inhabitants of Magnesia, in Thessaly. The Romans knew also that magnetism can act to repel, as shown by a quotation from the same passage: "Sometimes, too, iron draws back from this stone; for it is wont to flee from and follow it in turn." No reference to the north-pointing property of the magnet, as used in the compass (*q.v.*), is found in old Greek and Roman literature. To account for magnetic attraction some of these ancients believed that there were hooks on the surface of the magnet and little rings on the surface of the iron to catch them; others held that particles were emitted by the magnet and created an empty space toward which the iron would move.

Beginning in the period A.D. 1000–1200 the history of magnetism is closely connected with the compass and its use in navigation. According to G. A. L. Sarton, the first clear mention in any literature of a magnetic needle for indicating direction appears to have been made by Shen Kua (1030–93), a Chinese mathematician and instrument maker, who mentioned only its use on land.

Soon after 1100 the Chinese Chu Yu reported that in the period 1086–99 the compass was used for navigation by "foreign" sailors going between Canton and Sumatra. Since the trade in this region was practically a Muslim monopoly it is concluded that they were the first to use the compass for directing ships.

The earliest known European reference to the compass is by Alexander Neckam (1157–1217), an Englishman. In 1269 Petrus Peregrinus de Maricourt, a French crusader, gave the first detailed description of the compass as an instrument of navigation. He wrote of the floating compass as an instrument in common use and described a new pivoted compass in some detail. Maricourt fashioned a sphere of lodestone and explored its surface with bits of iron, and applied the term pole to the places in which the magnetic power appeared to be concentrated. He believed that the magnet derived its power from the sky.

After Maricourt's time little progress in understanding magnetism was made for almost 300 years. In 1600 William Gilbert of Colchester, Eng., physician to Queen Elizabeth I, published his *De magnete* which summarizes the knowledge of magnetism at that time and reports some of his own experiments. He mentioned the dip and declination of the compass and propounded his own great contribution, the discovery that the earth itself is a magnet. Gilbert showed that magnetized iron lost its magnetism when heated to a bright red heat and regained it when cooled to room temperature. His chapter xii of book v is entitled "Magnetic force is animate, or imitates life; and in many things surpasses human life, while this is bound up in the organick body."

After the time of Gilbert, during the period when Isaac Newton was formulating the law of gravitation and Robert Boyle was investigating the laws of gases, little of importance for magnetism was recorded.

1. Magnetostatics and the Nature of Magnetism.—In 1785 Charles Augustin de Coulomb established with some precision the inverse square law of attraction (and repulsion) between unlike

(and like) magnetic poles, a controversial proposition up to that time. This was made the basis of Siméon Denis Poisson's (1781–1840) mathematical theory giving the forces between magnetized bodies in terms of their intensities of magnetization. Poisson assumed magnetization to be a molecular phenomenon, but believed that a molecule became magnetic when two fluids it was supposed to contain became separated. In 1852 Wilhelm Eduard Weber proposed that each molecule is a permanent magnet, subject to a frictional force that tends to maintain it in its established orientation. This explained the limit of magnetization (saturation) and gave a rather unsatisfactory explanation of residual magnetization; *i.e.*, the magnetization remaining after the removal of the magnetizing field. Later James Clerk Maxwell (1831–79) improved upon Weber's explanation of residual magnetization by suggesting that the molecular magnet had no friction but had more than one fixed position of equilibrium.

Before the time of Weber, Hans Christian Oersted made the important discovery (1820) that an electric current would affect a magnetic needle. Quickly following up this lead, André Marie Ampère experimentally and mathematically investigated the mutual forces between currents and showed (1825) that a current in a circuit is equivalent to a magnetic shell of calculable strength. He considered magnetism as arising primarily from electric currents circulating within molecules. Though not accepted immediately because there was no way to verify or refute it, this concept stood the test of time and was elaborated with the advent of electron theory.

2. Electromagnetism.—Using Oersted's discovery, both Ampère and François Arago (1786–1853) magnetized steel needles by placing them in a helix of wire that carried an electric current. This was the prelude to the construction in 1825 of the first electromagnet which could be so called (fig. 1) by William Sturgeon (1783–1850). This was made of soft iron bent in the form of a horseshoe and wound with a loose helix of 18 turns of wire. When excited by a wet battery it could lift more than 20 times its own weight (*see* ELECTROMAGNET).

Several years later Joseph Henry built a much-improved electromagnet with many turns of wire efficiently applied. While experimenting with this in 1829 he noticed the spark that occurred when the circuit was broken and he was led to the discovery of self-induction, a treatise on which he published in 1832. The same phenomenon was independently discovered and published several years later by Michael Faraday (1791–1867). This great English experimentalist also shared with Henry the important discovery of electromagnetic induction, the conversion of magnetism into electricity. Although Henry is believed to have performed the experiment first and understood its significance, his results were unknown to Faraday who likewise made the crucial experiment and was the first to publish the results. Faraday and Henry made the first transformers (fig. 2) and prepared the way for the construction of the electric generator and motor (*see* GENERATOR, ELECTRIC; MOTOR, ELECTRIC).

The laws of electricity and magnetism were formulated systematically in mathematical language by Maxwell, and his famous treatise was published in 1873. (*See* ELECTRICITY: *Electromagnetic Waves.*)

3. Modern Theory.—One difficulty with Weber's theory was

FIG. 1.—STURGEON'S ELECTROMAGNET

that it gave no satisfactory explanation of residual induction and hysteresis (*q.v.*). Maxwell's suggestion of multiple fixed positions for the molecular magnet left unexplained the hysteresis that is found when a magnetizing force, after being once applied, is removed and reapplied. A. Ewing proposed (1890) that the constraints on the orientations of the molecular magnets were imposed by the magnetic forces of the surrounding molecules, and he showed by means of calculations and models that such forces can account qualitatively for the shape of the magnetization curve and the major and minor hysteresis loops. He first used the word hysteresis. J. Swinburne predicted on the basis of Ewing's theory that in a rotating magnetic field the hysteresis should disappear, and F. G. Baily's experiment (1896) confirmed this in a striking way (*see* fig. 25).

The first important influence of modern concepts on the theory of magnetism came when P. Langevin (1905) used statistical theory to explain the variation of paramagnetic susceptibility with temperature. He assumed each molecule to have a definite magnetic moment that tended to be oriented by the applied field and at the same time disturbed by thermal agitation. In 1907 this idea was seized upon by P. Weiss who postulated that the molecules are exposed both to the applied field and to a so-called molecular field that is proportional to the intensity of magnetization; thus he developed the first important quantitative theory of ferromagnetism. This molecular field is co-operative in nature, in that it depends on the mutual action of many atoms, and is now attributed to the exchange forces derived from quantum theory by W. Heisenberg.

It is a consequence of the Weiss theory that ferromagnetic materials must be spontaneously magnetized, that is, small regions (or domains) of the material are magnetized to saturation even when the specimen as a whole has zero intensity of magnetization, in which condition the magnetic moments of the regions are oriented at random. Previously such regions were considered identical with the molecules or atoms of the substance, but Weiss's deduction was later supported by many experiments (*e.g.*, those on the Barkhausen effect) and is the basis for the domain theory now used in the interpretation of many magnetic phenomena.

By its clarification of atomic structure the quantum theory has had a great influence on magnetic theories. W. Pauli in 1920 showed that there is a natural unit of magnetic moment, the Bohr magneton, and in 1926 S. A. Goudsmit and G. E. Uhlenbeck proposed the spinning electron as the fundamental magnetic particle having a moment of one Bohr magneton. The quantum theory of paramagnetism and ferromagnetism was developed rapidly by the contributions of Heisenberg, J. H. Van Vleck, E. C. Stoner, H. A. Bethe, F. Bloch, J. C. Slater and others. The temperature dependence of saturation magnetization, as calculated by

FIG. 2.—FARADAY'S TRANSFORMER HAS TWO WINDINGS OF COPPER WIRE ON AN IRON CORE. CONNECTION OF ONE WINDING TO A BATTERY CAUSES MOMENTARY FLOW OF ELECTRICITY IN OTHER WINDING CONNECTED TO A GALVANOMETER

P. J. W. Debye (1925), was a notable success of the quantum theory of ferromagnetism. Advances in the theory of diamagnetism were also made after Langevin's pioneering work of 1905.

II. GENERAL DESCRIPTION OF MAGNETISM

The quality of magnetism first apparent to the ancients, and to us today, is the attractive force that exists between a magnet and a piece of soft iron. When a magnet is dipped into iron filings they cling to it, especially at the poles, usually near the ends of the magnet (fig. 3). The poles occur in pairs, and in a magnet used as a compass needle the pole that points to the north is the north-seeking pole, or simply the north pole, and the other the south pole. When a magnet is broken new poles appear near the break so that each piece has the same number of poles of each kind.

1. Magnetic Field.—A magnet will attract a piece of iron even though the two are not in contact; this action at a distance is said to be due to the magnetic field, or field of force around the magnet. This field may be explored by sprinkling iron filings around a magnet, whereupon they form in lines that converge on

FIG. 4.—IRON FILINGS SHOW DIRECTION OF MAGNETIC FIELD NEAR BAR MAGNETS; NOTE LINES OF FORCE

the poles and indicate also the direction a small compass needle would take if placed at any point (fig. 4).

Poles exert forces on each other: north and south poles attract each other and like poles repel with a force that varies inversely as the square of the distance between them. A unit pole is a convenient concept defined so that two unit poles of like kind, one centimetre apart, repel each other with a force of one dyne. The strength of the field of force, or simply the magnetic field strength or magnetizing force, may be defined in terms of magnetic poles at one centimetre from a unit pole the field strength is one oersted. A magnetic field may be produced by a current of electricity as well as by a magnet and the unit of field strength can also be defined in terms of current. A magnetic field has direction as well as strength; the direction is that in which a north pole, subjected to it, tends to move, or that indicated by a small compass placed at the point. The field strength in oersteds is represented by the symbol *H*.

FIG. 5.—UNIFORMLY MAGNETIZED BAR. A POLE OF STRENGTH *m* AND AREA *a* CORRESPONDS TO AN INTENSITY OF MAGNETIZATION $I = m/a$, EQUAL ALSO TO MAGNETIC MOMENT PER UNIT VOLUME m/v . LINES OF INDUCTION ARE ENDLESS, PASS INTO THE MAGNET AT THE SOUTH POLE AND LEAVE AT THE NORTH POLE

2. Intensity of Magnetization and Magnetic Induction.

—To describe the magnetic properties of materials requires a quantitative measure of magnetization. Such a measure is the intensity of magnetization, defined in terms of the number of unit poles in a piece of given cross-sectional area. Suppose that a uniformly magnetized bar, of length *l* and cross-sectional area *a*, has *m* unit north poles at one end and *m* unit south poles at the other (fig. 5). The intensity of magnetization is then *m/a*, and is represented by the symbol *I*. It may easily be shown that *I* is also the magnetic moment per unit volume; for the magnetic moment is pole strength times interpolar distance ($M = ml$), and $I = M/v$, if *v* is the volume *al*.

Maxwell showed that some of the properties of magnetism may be likened to a flow, and conceived endless lines of induc-

FIG. 3.—MAGNETIZED BAR AND IRON FILINGS

FIG. 6.—PROPERTIES OF MATERIALS ARE DESCRIBED BY MAGNETIZATION CURVES (SOLID LINE) AND HYSTERESIS LOOPS (BROKEN LINE) OBTAINED BY PLOTTING I OR B AGAINST H ; THEY MAY ALSO BE DESCRIBED BY PERMEABILITY CURVES (μ PLOTTED AGAINST B)

tion that represent the direction and, by their concentration, the flow at any point. The lines pass from a magnetized material into the air at the north pole, enter again at a south pole, and pass through the material from the south pole back to the north to form a closed loop.

The total number of lines crossing a given area at right angles is the flux in that area. The flux per unit area is called the flux density or magnetic induction, and is represented by the symbol B . The lines of induction are due to both H and I , but in magnetic materials they are due mainly to the magnetization I . The magnetic induction is defined by the relation

$$B = H + 4\pi I$$

the unit of induction being the gauss. The factor 4π reflects the fact that a unit pole gives rise to a unit field everywhere on the surface of a sphere of unit radius enclosing the pole, and this sphere has an area of 4π . The lines of induction may be visualized with the aid of fig. 4 that shows the pattern obtained with iron filings.

3. Magnetization and Permeability Curves.—When a piece of iron is brought near a magnet, or subjected to the magnetic field of an electric current, the magnetization induced in the iron by the field is described by a magnetization curve obtained by plotting the intensity of magnetization I , or the magnetic induction B , against the field strength H . Such curves are of fundamental importance for describing the magnetic properties of materials, and many of them are shown on the following pages. A magnetization curve for iron is shown as the solid line of fig. 6 (left).

The behaviour of a material is also described by its permeability curve and hysteresis loop. The ratio B/H is called the permeability μ , and represents the relative increase in flux due to the presence of the magnetic material. The permeability curve is obtained by plotting μ against either I , B , H or $B - H$. In any case the curve rises from a point on the μ axis above the origin (the initial permeability) to a maximum (the maximum permeability) and falls off rapidly and then more slowly toward a value of one (not zero). When plotted against $B - H$ the curve ends at a definite point; i.e., when $B - H$ reaches its highest possible value, the saturation.

If the field strength is first increased from zero to a high value and then decreased, as indicated by the arrows of fig. 6, it is observed that the original curve is not retraced; the change of induction lags behind the change in field and follows the characteristic curve shown by the broken line. This phenomenon was named hysteresis by Ewing, and the characteristic curve is called a hysteresis loop. On this loop the value of H for which $B = 0$ is called the coercive force H_c , and is often used as a measure of quality of the material. Sometimes it is desirable to have H_c large, sometimes small; for different materials H_c may be higher

than 1,000 oersteds or lower than 0.01 oersted. The value of B for which $H = 0$ is called the residual induction B_r .

4. Kinds of Magnetism.—Materials that have magnetic properties similar to iron are ferromagnetic. They have permeabilities of considerable magnitude that vary with the field, they exhibit hysteresis and they lose these properties rather abruptly when heated to a temperature θ called the Curie point of the material. All solids, they usually contain iron, cobalt or other elements of the first transition series of the elements (titanium through nickel) or of the later transition series (rare earths). (See ELEMENTS, CHEMICAL.)

A larger class of materials with permeabilities only slightly greater than 1, usually between 1 and 1.001, does not show hysteresis. The permeability is generally independent of field strength, except at the lowest temperatures, and as a rule is either independent of temperature or decreases with increasing temperature. These materials are paramagnetic. Among them are many of the salts of the iron and the rare-earth families, the palladium and platinum metals, the elements sodium, potassium and oxygen, and the ferromagnetic materials when heated above their Curie points. The substances may be solids, liquids or gases.

In diamagnetic substances the magnetization is directed oppositely to the field; i.e., they have permeabilities somewhat less than one. They are, therefore, repelled from the poles of an electromagnet and move toward a weaker field. Many of the metals and most of the nonmetals are diamagnetic.

Paramagnetic and diamagnetic substances are described more conveniently by their susceptibilities than by their permeabilities. The susceptibility is a measure of the increase in magnetic moment caused by the application of a field and is defined as

$$\kappa = I/H$$

or the equivalent,

$$\kappa = \frac{\mu - 1}{4\pi}$$

For diamagnetic materials the susceptibility is negative, and for bismuth has a relatively large value of -0.000013 . For substances like iron the susceptibility may be as high as 500, or higher.

The kinds of magnetism denoted antiferromagnetism and ferrimagnetism are defined in terms of the arrangement of magnetic dipoles in the material. A simple paramagnetic material can be represented by fig. 7(A), the magnetism of the separate atoms being represented by arrows arranged in random directions with

FIG. 7.—TYPES OF MAGNETISM ASSOCIATED WITH VARIOUS KINDS OF ATOMIC INTERACTION

roughly equal to the magnetic constant. Qualitative changes are observed in the magnetizing curves and in the $B-H$ curve. In the case of ferromagnetic materials, the magnetizing curves are characterized by a steep slope and the magnetic susceptibility is high. In the case of paramagnetic materials, the magnetizing curves are characterized by a steep slope and the magnetic susceptibility is low. In the case of diamagnetic materials, the magnetizing curves are characterized by a steep slope and the magnetic susceptibility is negative.

has been regarded as an arrangement of small magnets and

represents a group of atoms. When the material is magnetized, the atoms are aligned with the magnetic field. The degree of alignment is determined by the strength of the magnetic field and the temperature of the material. The atoms are aligned in such a way that the magnetic field is reinforced. The degree of alignment is determined by the strength of the magnetic field and the temperature of the material.

The magnetic properties of materials depend mainly on the arrangement of the atoms. In the case of ferromagnetic materials, the atoms are arranged in such a way that the magnetic field is reinforced. In the case of paramagnetic materials, the atoms are arranged in such a way that the magnetic field is slightly reinforced. In the case of diamagnetic materials, the atoms are arranged in such a way that the magnetic field is slightly opposed.

sition and is most pronounced when the nickel content is 65% to 70%, as illustrated in fig. 11(C). The hysteresis loops of material that has undergone magnetic anneal have the characteristic rectangular shape illustrated in fig. 13. The sides are vertical and the corners are often perfectly square; the coercive force is much smaller than that of the same material heat-treated in the absence of a field. Such square-loop materials of various compositions are useful as elements for the storage of information in electronic computers (see COMPUTER).

3. Iron-Cobalt Alloys.—In the 1960s there was no satisfactory explanation for the observation that some alloys of iron and cobalt can show greater intensities of magnetization than either of these elements alone. The saturation magnetization is highest for alloys containing 35% to 40% cobalt, and then is 10% to 15% higher than for pure iron. When the field strength is 1,000 oersteds or below, the highest inductions are attained in the alloy that con-

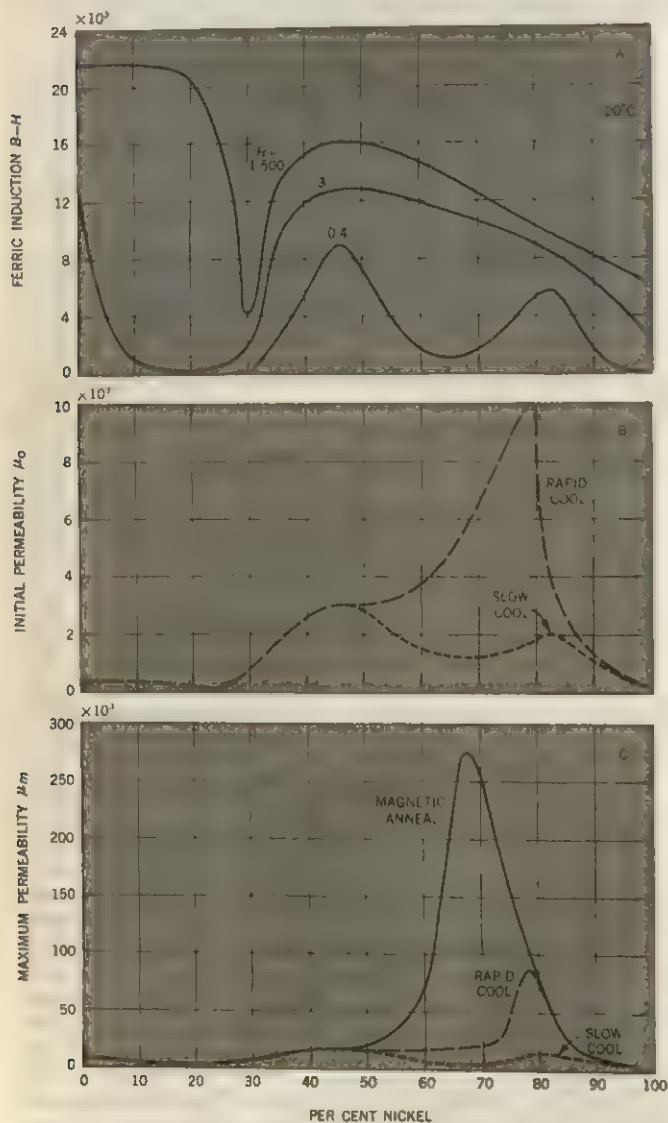

FIG. 11.—SOME MAGNETIC PROPERTIES OF IRON-NICKEL ALLOYS

tains equal proportions of the two elements, except that in fields weaker than 2 oersteds pure iron has the highest permeability.

The 50% alloy (permendur) is a useful component of the magnetic circuits of electromagnets and permanent magnets, where it is used for yokes and pole pieces. Since it is rather brittle and cannot be rolled to thin sheets, 2% vanadium is sometimes added and permits the fabrication of sheets a few thousandths of an inch thick. The properties of this vanadium alloy have been improved enormously by heat treatment in hydrogen and in a magnetic field; it is then called supermendur.

FIG. 12.—COMPARISON OF SUPERMALLOY WITH OTHER HIGH-PERMEABILITY ALLOYS (O. L. BOOTHBY AND R. M. BOZORTH)

Some alloys of iron, cobalt and nickel have permeabilities that are independent of field strength over a relatively large range. The same alloys have hysteresis loops of peculiar shape with low residual induction and a constricted middle portion. A representative alloy (perminvar) contains 30% iron, 25% cobalt and 45% nickel. The constancy of permeability with field strength in weak fields is brought out by annealing in the usual way at about 1,000° C. and then heat-treating for several hours at a relatively low temperature, 350° to 500° C. The hysteresis loss is then extremely small. The relationship between permeability and field strength, and a hysteresis loop for perminvar, heat-treated for 24 hours at 400° C., are shown in fig. 14. This material responds to heat treatment in a magnetic field, and a loop for a specimen so treated is also shown in the figure.

4. **Ferrites.**—After World War II the magnetic properties of

FIG. 13.—EFFECT OF ANNEALING IN PRESENCE OF MAGNETIC FIELD (DILLINGER AND R. M. BOZORTH)

a number of nonmetallic substances were investigated and subsequently found many applications in industry. The most important among these materials are the ferrites, which were developed largely as the result of the work of J. L. Snoek. Examples of important ferrites are nickel ferrite (NiFe_2O_4), manganese ferrite (MnFe_2O_4) and their combinations with zinc ferrite (ZnFe_2O_4). The ferrites are nonmetallic refractory materials composed of the oxides of iron and other metals, usually manganese, cobalt,

FIG. 14.—PROPERTIES OF PERMINVAR (G. W. ELMEN AND G. A. KELSALL)

nickel, copper, zinc or magnesium. The proper proportions of the oxides are pressed in powder form to the required shape and fired at 1,000° to 1,300° C. Chemical reaction occurs during the firing, and when the materials are cooled to room temperature they are hard strong and brittle.

The maximum induction attainable in the ferrites is generally lower than in metallic materials, as shown by the hysteresis loops of fig. 15. The permeability is also below that of the best alloys. However, the resistivities of the ferrites are 10^6 to 10^9 times

FIG. 15.—HYSTERESIS LOOPS OF NICKEL FERRITE AND ZINC MANGANESE FERRITE (SMALLEST LOOP) AS COMPARED WITH LOOPS OF METALLIC IRON AND MOLYBDENUM PERMALLOY

higher than for metallic materials, and greatly reduce the losses associated with changes in magnetization at high frequencies. For many applications, especially in communications engineering, the merit of a magnetic material is measured by the product μQ , μ being the permeability in weak fields and Q being inversely proportional to the energy loss per cycle. The variation of μ and μQ with

FIG. 16.—EFFECTIVE LOW-FIELD PERMEABILITY μ AND PRODUCT WITH QUALITY FACTOR Q (RECIPROCAL OF ENERGY LOSS) AS DEPENDENT ON FREQUENCY

frequency is shown in fig. 16, where the μQ of manganese-zinc ferrite is seen to become increasingly valuable at frequencies up to one megacycle.

A number of materials of high permeability are described in

5. Magnetic Compounds.

There are a large number of other compounds and alloys that are ferromagnetic. As early as 1903, C. Heusler discovered that alloys near in composition to the compound Cu_2MnAl were ferromagnetic, with a saturation (B_s) of about 5,500 gauss, nearly as high as for nickel. Similar alloys are known in which the aluminum is replaced by samarium, arsenic, antimony, bismuth, indium or gallium; or copper may be replaced by a larger amount of silver. Later many intermetallic and nonmetallic compounds of iron, cobalt, nickel, manganese and chromium were discovered.

Other ferrites have been the subject of increasing research and development. One such class (orthoferrite) is typified by GdFeO_3 , a combination of a rare-earth oxide and an iron-group oxide. Different structure (garnet type) and properties are obtained if the component oxides are combined in the ratio $3\text{Gd}_2\text{O}_3 \cdot 5\text{Fe}_2\text{O}_3$. Certain magnetic hexagonal ferrites have the formula $\text{BaO} \cdot 6\text{Fe}_2\text{O}_3$; others are of the type $m\text{BaO} \cdot n\text{MnO} \cdot p\text{Fe}_2\text{O}_3$, in which m , n and p have various integral values and the manganese may be replaced by other elements.

A great variety of compounds and alloys of the iron and rare-earth groups are now known to be ferromagnetic, many of them only at low temperatures.

IV. PERMANENT MAGNETS

Permanent magnets, as well as electromagnets, are used to produce fields of considerable strength and constancy. A host of devices depend on them for operation; e.g., loud-speakers,

magnetos, meters of many kinds, magnetrons and telephone receivers. In all of these the magnet necessarily contains an air gap; consequently it always operates under the influence of a demagnetizing field such as that existing at the middle of a short bar of magnetized material. Thus the magnet operates not at residual induction but at some lower value of the induction B .

The important curve for evaluating the quality and behaviour of material for permanent magnets is that portion of the hysteresis

loop that lies in the second quadrant, between residual induction B_r and coercive force H_c , and is called the demagnetization curve. Magnetization and demagnetization curves for alnico 5 (Alcomax) are shown in fig. 17.

The quality of a permanent magnet is characterized not only by B_r and H_c , but also by the so-called energy product BH for vari-

FIG. 19.—DEMAGNETIZATION AND ENERGY-PRODUCT CURVES FOR SEVERAL MATERIALS IMPORTANT FOR PERMANENT MAGNETS

ous points on the demagnetization curve. The curve (fig 18), showing this product as dependent on B , has a characteristic shape and the maximum energy product is the best single criterion of magnetic quality for these materials.

1. Alloy Magnets.—From ancient times until about 1930 materials used as magnets were carbon steels. After 1855 alloying elements, especially tungsten, were used to improve the quality. In 1916–17 chromium began to displace tungsten, and cobalt was added up to 40% with very beneficial effect.

From the standpoint of magnetic quality the best materials for permanent magnets available since 1950 have been dispersion-hardened (precipitation-hardened) alloys with no essential carbon, rather than steels (see ALLOYS). The first materials of this kind to find commercial use were the iron-cobalt-molybdenum and iron-nickel-aluminum alloys. Their high coercivities result from the presence of very small particles of one kind highly dispersed in a matrix of another composition.

Important materials for magnets are listed in Table III which indicates in outline the mechanical operations required in preparation and the heat treatment used to develop the best magnetic properties. Demagnetization curves for some of these alloys are reproduced in fig. 19. Special attention is called to the alloy called alnico 5 in the U.S. and Alcomax in England. To develop its remarkable properties it must be cooled at a definite rate in a strong magnetic field (about 1,000 oersteds) so directed in the specimen that it is parallel to the field required in use. At right angles to the direction of the field that has been applied during treatment the properties are not so good, the energy product being then only about one-tenth as high. Although alnico 5 is not forgeable and must be cast and ground to final form, its magnetic properties are outstanding and it has numerous uses.

2. Fine-Particle Magnets.—Among the other materials used or contemplated for use in permanent magnets the most interesting are in the class of fine-particle magnets. Theory indicates that when particles are small enough, of the order of one micron (10^{-4} cm.) or less in diameter, they are comprised of single domains (see V. *The Magnetization Curve*; 5. *Domain Theory of Magnetization* below). This means that it is more difficult to reverse the magnetization in them than in larger particles of the same material and that therefore they will make good permanent magnets.

Permanent magnets have been made of finely divided powder of barium ferrite ($\text{BaFe}_{12}\text{O}_{19}$, Ferroxdure), of iron, of manganese bismuthide (MnBi) and of iron-cobalt ferrite (CoFe_2O_8). In 1956 magnets of a finely powdered iron-cobalt alloy were prepared by T. O. Paine and his associates with an energy product of 5×10^8 (see fig. 19). In this material the shape of the particle is important (the length is several times the diameter) and the long directions of the particles are all aligned parallel to the direction in which the material is to be magnetized.

It has been proposed that such materials as alnico 5, although they are cast, fall into the category of fine-particle magnets because they are composed of particles of the requisite fineness embedded in a matrix of different magnetic quality.

3. Design of Permanent Magnets.—In the design of permanent magnets it is important to use the appropriate material and to shape it so that the minimum amount is used to produce the desired field strength in a given gap. As already pointed out, this result is accomplished when the energy product everywhere in the material has its maximum $(BH)_m$. The magnet of fig. 20 is designed with that in mind. Except for the iron pole piece the material is alnico 5. The length of the material along the curved path, in relation to the length of the gap, determines the position of the line OP of fig. 18, and this should be placed so that it cuts the demagnetization curve at $B = 10,000$, corresponding to $(BH)_m$. The cross-sectional area of the magnet is adjusted to take account of leakage; a heavier section is necessary at the lower part because all of the leakage flux must pass through this, and B must at the same time be maintained at its proper value.

After a permanent magnet is designed and constructed it is magnetized with a high-strength field. After removal of this magnetizing field it is usually desirable to apply momentarily a relatively weak field in the opposite direction, whereupon the magnetic state of the material changes as indicated by the points PQR of fig. 18. This stabilizes the magnet against the effect of stray fields, mechanical shocks or changes in temperature, and the field in the gap is less likely to change.

V. THE MAGNETIZATION CURVE

1. Three Portions of Curve.

—A typical magnetization curve, showing the relation between B and H in a specimen that is ini-

FIG. 22.—NORMAL HYSTERESIS LOOPS FOR LOW, INTERMEDIATE AND HIGH INDUCTIONS. RESIDUAL INDUCTION B_r , AND COERCIVE FORCE H_c , ARE VALUES OF B AND H WHERE CURVES CROSS AXES

tially unmagnetized, may be divided into three main parts separated from each other by the knee and the instep (fig. 21). These three regions are identified with different mechanisms of change of magnetization, and also with different engineering uses of the materials. The initial portion of the curve, the toe, is not horizontal at the origin but has a definite slope called the initial permeability μ_0 equal to B/H for $H = 0$. For low inductions Lord Rayleigh found that the relation

$$B = \mu_0 H + aH^2$$

was obeyed. When the permeability μ is plotted against the field strength H the points usually lie on a straight line corresponding to the equation

$$\mu = \mu_0 + aH$$

Curves of this kind are used to determine the value of μ_0 by extrapolation.

The upper portion of the magnetization curve (fig. 21) bends over and approaches the horizontal line marked B_s . In strong fields, however, it is found that B approaches no definite limit but $B - H$ does approach a limit, called the saturation induction or simply saturation, designated B_s . Since $B - H = 4\pi I$, I approaches the limit I_s , the saturation magnetization.

The upper part of the curve may be represented fairly well by O. Fröhlich's equation

$$B - H = H/(a + bH)$$

in which $b = 1/B_s$, and a is a constant which measures the magnetic hardness and is larger the stronger the field necessary to attain any given fraction of saturation. When H is small enough to be neglected in comparison with B , this equation may be expressed in the equivalent form used by A. E. Kennelly

$$1/\mu = a + bH$$

and so a linear relation is found when $1/\mu$ is plotted against H . From a graph of this kind one can easily determine the constants a and b , and interpolate to find the value of μ for intermediate values of H . The slope b of the line may be used to estimate the saturation induction (since $b = 1/B_s$), but this method cannot be depended on for accuracy; in some materials such as iron the slope changes markedly at inductions close to saturation. The ratio $1/\mu$ is termed the reluctivity.

FIG. 21.—THREE SECTIONS OF NORMAL MAGNETIZATION CURVE. THE SECTIONS ARE SEPARATED BY KNEE AND INSTEP. μ_m IS LARGEST VALUE OF B/H , μ_0 INITIAL SLOPE OF CURVE

In its middle portion the magnetization curve is the steepest, and the permeability has its greatest value. It is here that irreversible changes in magnetization are a maximum; curves for increasing and decreasing field strength differ markedly. These irreversible changes and the consequent losses in energy will now be discussed.

2. Hysteresis Loops.—A set of normal hysteresis loops is shown in fig. 22. In forming one of these the field strength is first increased from zero and the induction follows the magnetization curve OAC. H is then decreased, and the induction decreases slowly so that the hysteresis loop passes successively through the points D, E and F; then the field is reversed and the loop passes through G and back to C. At D the induction is called residual induction B_r , and at E, when $B = 0$, the field strength is the coercive force H_c . The induction at the tip of a loop, as at C, is commonly designated B_m .

When the tip of the hysteresis loop lies on the first portion of the magnetization curve (OP in fig. 22), the loop is relatively narrow and the slope of the upper part of the loop, after it has just receded from the tip, is not greatly different from the slope of the magnetization curve at that point. If the tip lies in the middle portion of the magnetization curve, however, the slope of the loop (e.g., at C, going toward D) is markedly different from the slope of the magnetization curve. These loops are relatively wide and the energy losses are large. In the upper portion of the curve, above the knee, the losses are again small and the process of magnetization is reversible.

The area enclosed by a hysteresis loop is proportional to the energy liberated as heat during traversal of the loop. When the area is in gaussses \times oersteds the energy loss due to hysteresis (Warburg's law) is

$$W_h = \frac{\text{area}}{4\pi} = \frac{1}{4\pi} \oint H dB$$

ergs/cm.³ for each traversal of the loop, or cycle. In strong fields the hysteresis loss in iron, about 10,000 ergs/cm.³/cycle, is sufficient to raise its temperature about 0.0003° C. for each cycle; thus if the field is alternated 50 or 60 times a second, about one minute is required for the iron to heat one degree.

The hysteresis loss rises rapidly as the maximum induction B_m of the loop increases. The curve of fig. 23 shows the relation between W_h and B_m for ordinary iron with a maximum permeability of 4,500. When B_m is very small W_h varies as B_m^3 , and in the range $B_m = 1,000$ to 15,000, of special interest for work on power transformers, it varies in accordance with the empirical law of C. P. Steinmetz

$$W_h = \eta B_m^{1.6}$$

in which the Steinmetz coefficient η is approximately constant for any one material. The B^3 relation at low inductions was derived by Rayleigh. He showed, as noted above, that the magnetization curve near the toe followed the equation

$$B = \mu_0 H + aH^3$$

and also that the hysteresis loop with tips at (B_m, H_m) and $(-B_m, -H_m)$ was described by parabolic equations

$$B = \mu H + (a/2)(H_m^2 - H^2)$$

$$B = \mu H - (a/2)(H_m^2 - H^2)$$

for the upper and lower halves of the loop, respectively. (Here $\mu = B_m/H_m$). Such a loop is shown with the corresponding magnetization curve in fig. 24. Measurements have been made for values of B_m as low as two gaussses, and only slight deviations from the Rayleigh form have been observed. The area of a Rayleigh loop may be calculated from the above equations, and the corresponding hysteresis loss, expressed in ergs/cm.³/cycle, is

$$W_h = \frac{aH_m^3}{3\pi} = \frac{aB_m^3}{3\pi\mu^3}$$

This equation corresponds to the lower part of the long curve of fig. 23, and is valid in iron when B_m is below about 500 gaussses.

The hysteresis losses of various materials vary over a wide

FIG. 23.—HYSTERESIS LOSS AS DEPENDENT ON MAXIMUM INDUCTION FOR SOME IMPORTANT MATERIALS

range. Losses of some of the common permeable materials are indicated by curves in fig. 23, and one of these has about 100 times the loss of iron at the same value of B_m . Materials used for permanent magnets, on the other hand, have hysteresis losses enormously larger than iron, sometimes by a factor of 500. Thus the over-all range in loss in various materials is approximately 100,000 times; i.e., the coefficient η of Steinmetz' equation varies from 0.6×10^{-5} to 0.6.

3. Distribution of Hysteresis Loss Over Cycle.—The energy loss and the attendant rise in temperature can be calculated satisfactorily as described above for a complete hysteresis loop. The question of where in the loop most of the rise in temperature takes place has been answered by direct experiment, measurements having been made of the very small rise in temperature that occurs when the induction is changed by only a small fraction of the total. Changes of about $\frac{1}{1,000,000}$ ° C. have been measured in these experiments. The results of such investigations show that the energy losses are largest where the hysteresis loop is steepest. In addition to this irreversible loss, there is a heating of the specimen in strong fields as the field is increased, and an equal cooling as the field is decreased. This reversible heat does not, therefore, contribute to the hysteresis loss over a complete cycle.

4. Hysteresis in Rotating Fields.—The hysteresis loops mentioned so far have been measured with B and H either parallel or antiparallel to each other. A different result is obtained if the field acting on a specimen is maintained constant in strength

FIG. 24.—FORM OF HYSTERESIS LOOP FOR LOW INDUCTIONS (LORD RAYLEIGH)

FIG. 25.—ROTATIONAL HYSTERESIS LOSS GOES THROUGH MAXIMUM, APPROACHES ZERO AT SATURATION (A. PERRIER)

ating hysteresis goes through a maximum and decreases rapidly, approaching zero at saturation. The disappearance of hysteresis in a high rotating field was predicted as a result of Ewing's work, and its confirmation in 1896 indicated the fundamental soundness of his theory. Rotational hysteresis is of practical importance in the magnetic material that forms the segments or teeth of rotating dynamoelectric machinery.

5. Domain Theory of Magnetization.—Many of the phenomena of the magnetization curve and hysteresis loop can be described to advantage in terms of the domain theory. The theory that a ferromagnetic material is composed of many small regions (domains), each magnetized to saturation in some direction, was first stated by Weiss in 1907, and the description he gave at that time was accepted in the 1960s with but slight modification. The existence of such domains is evident from H. Barkhausen's experiments and even more definitely from the study of powder patterns (see below). In the unmagnetized state the directions in which the domains are saturated (the directions of easy magnetization) are distributed either at random or in some other way such that the resultant magnetization of the specimen as a whole is zero. Appli-

and varied continually in direction. This is commonly called rotational hysteresis as compared with the usual alternating hysteresis. Measurement of rotational hysteresis is accomplished by rotating a disk of the material to be examined between the poles of an electromagnet so that H always lies in the plane of the disk. The force necessary to turn the disk is then a measure of the rotational hysteresis loss.

As the field strength increases from zero the rotational hysteresis first increases rapidly (fig. 25), more rapidly than the alternating hysteresis, but when the induction is one-half to three-quarters of saturation the alter-

FIG. 27.—NATURE OF CHANGE IN MAGNETIZATION IN RELATION TO POSITION ON MAGNETIZATION CURVE AND HYSTERESIS LOOP

cation of a magnetic field changes only the direction of magnetization in a given volume. The three main parts of the magnetization curve are distinguished from each other by the nature of this change in direction of magnetization, which may take place in any of several ways.

The magnetic moment of any one domain is specified by the magnitude and direction of its magnetization and by its volume. Ordinarily at constant temperature the moment of a domain, and therefore the magnetization of the ferromagnetic body of which it is a part, is changed by: (1) a change in the direction of magnetization of the domain (rotation); or (2) a change in the volume of the domain (moving boundary). These processes are indicated graphically in fig. 26. It has been shown by R. Becker that the moving boundary is particularly important for changes in low- and medium-strength fields. Processes may be classified also as reversible or irreversible accordingly as the energy dissipated in heat is a relatively small or large fraction of the potential energy.

In each of these portions of the magnetization curve, one type of process preponderates as follows: (1) initial portion—reversible boundary displacement; (2) middle portion—irreversible boundary displacement; (3) upper portion—reversible rotation. Fig. 27

FIG. 29.—POWDER PATTERN OF DOMAIN WALL MOTION IN COBALT (H. J. WILLIAMS)

shows for a specimen of high-permeability alloy the three important processes in relation to the magnetization curve and hysteresis loops, and the corresponding energy losses due to hysteresis.

The domain boundaries are not sharp on an atomic scale; as shown in fig. 28 the orientations of the atoms change progressively across the wall. In iron the wall is about 1,000 atoms thick instead of the three indicated in the schematic drawing.

If the dimensions of a magnetic particle are about the same as the wall thickness it is apparent that there can be no change in magnetization by wall displacement. Change in magnetization must then occur by domain rotation, and stronger fields are necessary to produce a given change in magnetization, provided that the particles are magnetically anisotropic. Consequently an agglomerate of fine particles will make a good permanent magnet.

The factors that determine the direction of magnetization in a single domain of a specimen are the crystal structure, the state

FIG. 30.—DOMAIN STRUCTURE IN [100] PLANE OF IRON, SHOWING TRIANGULAR DOMAINS OF CLOSURE AT EDGE OF CRYSTAL. UNMAGNETIZED (H. J. WILLIAMS)

of strain and, of course, the direction and strength of the magnetic field. The effect of crystal structure and of strain will be discussed in some detail later. It may be mentioned in a preliminary way that the nature of the crystal structure affects mainly the upper part of the magnetization curve of a permeable material. In iron, for example, the crystal structure is such that the magnetic properties of a single crystal vary considerably with direction, and as a result of this variation exceptionally strong fields are necessary to approach saturation in ordinary polycrystalline iron. The rotation of the domain by the field must be made against relatively powerful forces, and so the magnetization curve above the knee rises slowly over a considerable distance. In contrast, with permalloy, composed of 60% to 80% nickel and 40% to 20% iron, the magnetic properties vary but little with the direction in the crystal, the domains therefore rotate easily and the magnetization curve

FROM "FERROMAGNETISM," R. M. BOZORTH, BY COURTESY OF D. VAN NOSTRAND CO., INC., 1951-53

FIG. 31.—SECONDARY WALLS FROM SUBSURFACE CRYSTAL IMPERFECTION RESTRICT PRIMARY WALL AS IT MOVES DOWNWARD UNDER INFLUENCE OF APPLIED FIELD (R. C. SHERWOOD)

flattens out quickly above the knee, reaching saturation in relatively weak fields (fig. 9).

Magnetization changes the dimensions of a ferromagnetic body, and the body is said to exhibit magnetostriction. If length changes by a relatively large amount when a substance is magnetized to saturation, this material also will be relatively sensitive to strain; i.e., magnetostriction and strain sensitivity are reciprocal properties. Strain affects mainly the lower and middle portions of the magnetization curve, and the strain and magnetostriction together determine the ease with which the interdomain boundary is moved by a change in the magnetic field. Thus the highest initial permeabilities are found in materials that have very small magnetostriction; e.g., permalloy with about 80% nickel.

6. Powder Patterns.—For many decades iron filings have been used to portray the directions of lines of magnetic force in air and to detect flaws or inhomogeneities in magnetic materials. (See NONDESTRUCTIVE TESTING.) In 1931 it occurred to L. von Hämö

and P. A. Thiessen to use fine magnetic powder to detect the local inhomogeneities in magnetization that the domain theory predicts. Independently F. Bitter applied a suspension of siderac (Fe_2O_3), with particles about 10^{-4} cm. in diameter, to a polished magnetized surface and observed under the microscope that the powder formed parallel lines regularly spaced about 0.1 mm. apart and approximately perpendicular to the direction of magnetization. The technique and interpretation of such patterns were then the subjects of study by a number of workers. A notable advance was made by H. J. Williams, R. M. Bozorth and W. Shockley, who used carefully prepared surfaces of single crystals of silicon iron and other substances. They and other experimenters confirmed many of the processes predicted by domain theory. Fig. 29 shows a domain pattern on a single cobalt crystal; the motion of the boundaries with change in direction of applied field can be seen. In fig. 30, a domain pattern near the edge of a crystal of iron, both 180° and 90° walls (between domains magnetized in opposite directions and at right angles) are observed. The small domains at the bottom are domains of closure and permit the flux to flow easily in the directions of easy magnetization indicated by the arrows. A discussion of the easy directions of magnetization is given in VII. Properties of Single Crystals below.

The effect of imperfections on wall movement is illustrated by the two parts of fig. 31. In (A) the imperfection is near a principal wall which moves under the influence of a field, and from the imperfection there are subordinate walls stretching from the principal wall. But when this wall moves too far from the imperfection the subordinate walls are stretched too far and ultimately break, thus releasing the energy stored in the subordinate walls, and the principal wall moves forward suddenly.

The structures of some powder patterns are simple and well understood. It is believed that the more complicated patterns are controlled by the same factors, illustrated in fig. 32.

The energies involved are: (1) magnetostatic energy, associated with magnetic charge or poles; (2) magnetostrictive energy, associated with the spontaneous change in dimensions of a domain

when it is formed as a magnetic unit; and (3) the energy associated with the domain wall. In the various configurations of fig. 32, (A) shows a single isolated domain with a large amount of magnetostatic energy; in (B) this is reduced but some wall energy is added; in (C) the magnetostatic energy is further reduced but magnetostrictive energy, associated with nonparallel domains, is added; and in (D) the latter is reduced and some domain wall energy is added. The stable configuration is that for which the total energy is a minimum. The amounts of energy can be evaluated for simple configurations such as the one shown, and quantitative agreement with experiment is found. The resemblance between fig. 32(D) and fig. 30 is easy to see. Complex structures presumably are subject to the same principles.

7. Barkhausen Effect.—In 1919 Barkhausen discovered the effect known by his name, and interpreted it as demonstrating that the magnetization of iron proceeds by steps and not in a continuous manner. This effect may be demonstrated simply with the aid of amplifier and headphones. As the field is changed slowly the succession of clicks heard in the headphones, or in a loud-speaker, persists only when the magnetization is changing along the steep part of the magnetization curve or hysteresis loop. The clicks are identified with irreversible changes in magnetization (process [2] above) and are direct evidence of the existence of domains.

It is now known that the discontinuities of the Barkhausen effect result from the sudden movement of a portion of a domain wall from one stable position to another, the positions of stability being determined by the location of crystal imperfections. During one discontinuity in magnetization the volume of the material swept over by the wall is on the average about 10^{-8} mm.³, whereas the volume of a single domain is of the order of 10^{-8} mm.³

VI. STRESS AND MAGNETOSTRICTION

The magnetic properties of many ferromagnetic materials are so sensitive to the application of stress that stress may be ranked with field strength and temperature as a primary factor affecting magnetic change. Stresses of two kinds should be distinguished: large stresses that permanently deform the material almost invariably produce a decrease in permeability; stresses within the elastic limit may either increase or decrease the permeability, depending on the nature of the material.

When moderate tension is applied to a specimen of nickel, permeability is decreased. The magnetization curve taken with tension applied always lies below that for the unstrained material (fig. 33), and the curve is always lower with greater tension. The effect of stress on the magnetization curve is greatest in the middle portion of the curve, and approaches zero when the specimen is unmagnetized or saturated.

With some materials, on the other hand, the effect of tension is to increase permeability. For example, in 68 permalloy (68% nickel and 32% iron) the maximum permeability is higher by a factor of 8 when the tension is 2 kg./mm.² and by a factor of about 30 when the tension is 11 kg./mm.² (about 15,600 lb./in.²), the elastic limit of this material. As the stress exceeds the elastic limit the permeability of any material decreases rapidly.

The effect of stress on magnetization is closely related to magnetostriction, the change of dimensions that occurs when a body is magnetized; that is, the effect of strain on magnetization and the effect of magnetization on strain are interdependent. When nickel is magnetized it contracts a small fraction of its original length l , at most 40 parts per 1,000,000. The fractional change of length $\Delta l/l$ with field strength H is first slow, then rapid, then again slow

FIG. 32.—POSSIBLE DOMAIN STRUCTURES (see TEXT EXPLANATION)

FIG. 33.—EFFECT OF TENSION ON MAGNETIZATION OF 68 PERMALLOY AND NICKEL. TENSION IS HELD CONSTANT WHILE FIELD IS INCREASED FROM ZERO

FIG. 34.—APPLICATION OF FIELD CAUSES INCREASE IN LENGTH OF 68 PERMALLOY (POSITIVE MAGNETOSTRICTION), AND A DECREASE IN NICKEL (NEGATIVE MAGNETOSTRICTION). COMPARE WITH RECIPROCAL EFFECT OF FIG. 33

as it approaches a finite limit called saturation magnetostriction $(\Delta l/l)_s$. When 68 permalloy is magnetized it increases in length as shown (fig. 34).

Nickel and 68 permalloy respectively represent materials with negative and positive magnetostriction. Tension increases the magnetization of a body that exhibits positive magnetostriction, and decreases the magnetization if it has negative magnetostriction. The effect of compression is opposite to that of tension; consequently the magnetization of magnetostrictively positive materials is decreased by pressure. In this discussion it has been assumed that tension and compression are applied parallel to the direction of the magnetic field; if pressure is applied at right angles to the field the effect on magnetization is the opposite; *i.e.*, compression applied to nickel at right angles to the field will decrease the magnetization measured parallel to the field.

Iron and some other materials have magnetostriction that is sometimes positive and sometimes negative. The magnetostriction of iron is positive in weak fields and negative in strong fields; the effect of tension is, as expected, to increase magnetization in weak fields and to decrease it in strong fields.

Generally the magnetostriction begins to increase rapidly with field strength at about the knee of the magnetization curve. The magnetization reaches one-half to two-thirds of its saturation value while the magnetostriction is still only one-fourth to one-third of its final value $(\Delta l/l)_s$.

Both the strain sensitivity and magnetostriction of the iron-nickel alloys are of special interest. The saturation magnetostriction (the greatest change in length) goes through zero at about 81% nickel, a composition close to that of the permalloys with the highest permeability; L. W. McKeehan has pointed out the close theoretical connection between the low magnetostriction and high permeability of these alloys. The strain sensitivity of the permalloys is also zero at about 81% nickel, as would be expected.

Large magnetostriction has been reported for iron-cobalt ferrite ($\text{CoFe}_2\text{O}_4 \cdot \text{Fe}_3\text{O}_4$) at room temperature: about 750×10^{-6} . At low temperatures so-called "giant" magnetostriction has been observed in the rare-earth elements holmium and dysprosium: 7000×10^{-6} .

Measurements of magnetostriction are commonly made with strain gauges, as proposed by J. E. Goldman. These are fine wires cemented firmly to the surface of the body to be measured. When the body expands or contracts, the wire expands or contracts with it and the resistance of the wire changes accordingly. The resistance can be measured with high accuracy so that the change in di-

mensions can be determined to 1 part in 10,000,000 to 100,000,000 (10^{-7} to 10^{-8}).

1. Changes in Volume.—When iron is magnetized in not too strong a field its length increases and its cross-sectional area decreases in about the same proportion, leaving the volume approximately constant. A small change in volume, usually an expansion, can be detected with sensitive apparatus. When a field of about 2,000 oersteds is applied, the fractional change in volume in iron is about 10^{-6} , and in nickel about one-third of this amount. It is relatively large in the iron-nickel alloys with about 30% nickel, amounting to about 40×10^{-6} .

Closely connected with the change in volume with field strength is the change of magnetization with hydrostatic pressure. As indicated by the magnitude of the volume magnetostriction, this change is small.

2. Domain Interpretation of Stress.—According to the domain theory, in a material with positive magnetostriction, the magnetization of a single domain will tend to be parallel to the direction of tension. In an unmagnetized material with domains oriented initially at random the domains are rotated by a sufficiently large tension, as shown in fig. 35(A) and (B), because the directions of easy magnetization in the various domains have been changed by the stress. If a field is then applied (fig. 35[C]), half of the domains reverse in direction and the material is saturated. (No magnetostrictive change in length accompanies such domain reversals.)

Compression makes the domains orient transversely (fig. 35[D]).

FIG. 35.—EFFECT OF STRESS AND MAGNETIC FIELD APPLIED TO MATERIAL WITH POSITIVE MAGNETOSTRICTION

alloys with about 80% nickel; the equation holds with fair accuracy for a series of iron-nickel alloys. For $(\Delta l/l)_s$ the magnetostriction for polycrystalline material can usually be used, but it is represented more accurately by the magnetostriction measured in the direction of easy magnetization in a single crystal.

VII. PROPERTIES OF SINGLE CRYSTALS

Improvements in the technique of growing large metallic crystals have opened to investigation the magnetic properties of single crystals of iron, cobalt, nickel and many alloys of these elements as well as the nonmetallic ferrites. Crystals of some metals, such as nickel and nickel-iron alloys, are grown by slow-freezing a melt of pure material. This method is not adapted to iron, because of the phase transformation of iron at about 900°C. ; single crystals of this element are grown by stretching a pure specimen a definite

have the same result, and a field subsequently applied will rotate the domains toward saturation.

The domain theory has been successful in predicting the highest value of the initial permeability that can be attained when impurities have been reduced to a minimum and internal strains have been relieved as much as possible by annealing. The small remaining strain is from the magnetostriction of the separate domains and is proportional to the saturation magnetostriction; the smaller the magnetostriction the larger the initial permeability according to the relation derived by M. Kersten

$$\mu_0 = \frac{4\pi I_s}{(\Delta l/l)_s E}$$

in which E is Young's modulus of elasticity and I_s is the saturation magnetization. This equation, although by no means exact, is in agreement with the finding that μ_0 is large when $(\Delta l/l)_s$ is small, as it is in the iron-nickel

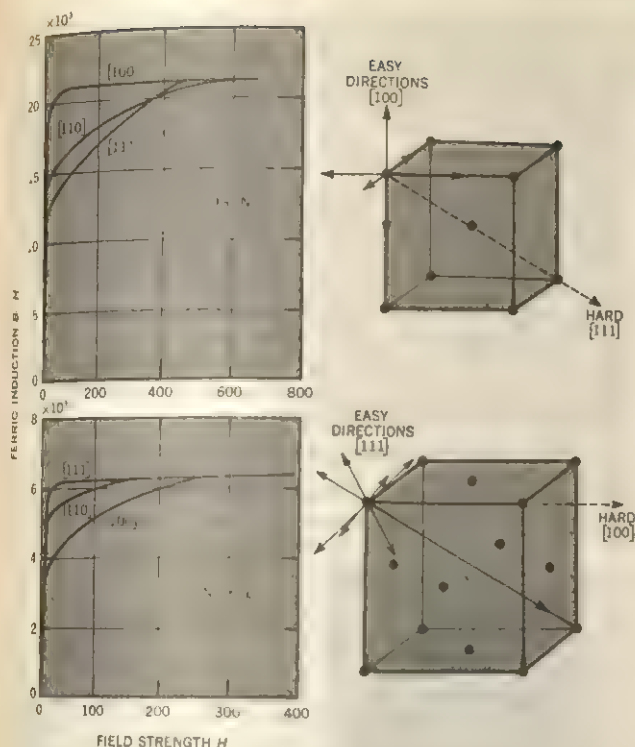

FIG. 35.—MAGNETIC PROPERTIES AND CRYSTAL STRUCTURES OF SINGLE CRYSTALS OF IRON AND NICKEL (K. HONDA AND S. KAYA, W. L. WEBSTER)

amount and then heating it for a long time just below the transformation temperature.

In the cubic crystals of iron and nickel the magnetic properties depend on the direction, with respect to the crystal axes, in which these properties are measured. Fig. 36 shows magnetization curves for iron and for nickel, with B and H measured in the three principal directions: (1) parallel to an edge of the cube—the $[100]$ direction; (2) parallel to a diagonal of a cube face—the $[110]$ direction; and (3) parallel to the space diagonal—the $[111]$ direction. (See CRYSTALLOGRAPHY: *Translational Order in Crystals.*) The direction for which the magnetization curve lies highest is the direction in which magnetization is most easily acquired, and is called the direction of easy magnetization. In iron this direction is parallel to a cube edge; in nickel it is parallel to a cube diagonal.

According to the domain theory the direction of easy magnetization in a crystal determines the actual direction of magnetization in a single domain that is not subjected to magnetic field or strain. In unmagnetized iron the domains are oriented in each of the six directions parallel to a cube edge so that the net magnetization is zero. In nickel there are eight such easy directions.

Magnetization curves of single crystals of a silicon-iron alloy

FIG. 37.—COMPARISON OF THEORY AND EXPERIMENT FOR MAGNETIZATION OF IRON-SILICON CRYSTAL IN THREE PRINCIPAL DIRECTIONS (H. J. WILLIAMS)

(3.8% silicon) are of special interest because this is the first case in which measurements were extended to very low inductions, and because the permeabilities obtained in these crystals are enormous compared with those in commercial silicon-iron sheet with the same silicon content. These data were obtained by cutting a single crystal in the form of a hollow parallelogram with all sides parallel to equivalent directions in the crystal (e.g., parallel to diagonals of cube faces), so forming a closed magnetic circuit, and by measuring in the usual way. The highest permeability observed is about 100 times that of commercial transformer sheet.

1. Calculation of Magnetization Curves.—A theoretical study of the properties of crystals has made it possible to calculate the magnetization curve for any direction in a single cubic crystal like iron or nickel, provided that a single constant of the crystal (the anisotropy constant K) is known. This constant is a measure of the difference between the magnetization curves in different directions, and is numerically equal to four times the area between the curves showing the relationship between I and H for the $[100]$ and $[110]$ directions. The constant is positive for iron, negative for nickel, and is approximately zero for iron-nickel alloys with 65% to 80% nickel.

Comparison of theory and experiment is made in fig. 37 using Williams' data for a single crystal that contained 3.8% silicon, for which $K = 280,000$ ergs/cm.³; the theory does not take account of the energy associated with the lower and middle portions of the magnetization curve; therefore, the calculated curves do not cor-

FROM "THE PHYSICAL REVIEW," BY COURTESY OF THE AMERICAN PHYSICAL SOCIETY
FIG. 38.—CRYSTAL ANISOTROPY CONSTANTS OF IRON-NICKEL ALLOYS AFTER QUENCHING OR SLOW COOLING (R. M. BOZORTH AND J. O. WALKER)

respond to the true magnetization curve below its knee. In a polycrystalline material the magnetization curve is a combination of the separate curves for the many small single crystals of which it is composed. Such a composite curve has been calculated to show how the magnetization curve approaches saturation, and shows fair agreement with empirical data.

In iron and nickel the anisotropy constants decrease as temperature increases; thus these metals are isotropic over a considerable range of temperature before they become nonmagnetic at the Curie point. At very low temperature (20° K.) the constant for nickel is 10 to 15 times what it is at room temperature, while for iron the corresponding ratio is only 1.5.

FIG. 39.—CRYSTAL ANISOTROPY OF COBALT REVERSES SIGN AT ABOUT 270° C., DIRECTION OF EASY MAGNETIZATION CHANGING FROM HEXAGONAL AXIS [001] BY 90° TO [100] (K. HONDA AND H. MASUMOTO)

2. Anisotropy.—Unusual magnetic properties are found in alloys with small anisotropy constants. Such alloys are the perm-alloys that contain between 60% and 80% nickel, in which range the constant goes from positive to negative (fig. 38). When the anisotropy is small, and the orientation of the domain therefore is controlled only weakly by the crystal structure, the material responds easily to magnetic field or to mechanical stress; thus it saturates in relatively weak fields and is unusually strain sensitive.

The small anisotropy of the perm-alloys with 60% to 80% nickel is associated with their unusual properties under heat treatment in a magnetic field. A hysteresis loop of material so treated (fig. 13) and the high values of maximum permeability associated with the perm-alloys have already been mentioned.

Cobalt differs from the other ferromagnetic elements, iron and nickel, by having a hexagonal rather than cubic crystal structure. At room temperature the direction of easy magnetization is parallel to the hexagonal axis of the crystal, and when unmagnetized the domains therefore lie in one of the two orientations parallel to this axis.

Such a small number of easy directions, compared with the six or eight in a cubic crystal, means that the domains are needlelike and that the whole magnetic structure may be regarded as a bundle of needles magnetized initially in either direction at random. This picture is supported by powder patterns (see fig. 29) and by L. H. Germer's measurements of magnetic fields close to the surfaces of a single crystal of cobalt.

The crystal anisotropy of cobalt is large; consequently a strong

FIG. 40.—DEPENDENCE OF MAGNETOSTRICTIVE CHANGE IN LENGTH ON CRYSTAL DIRECTION IN IRON (W. L. WEBSTER)

field is necessary to saturate a crystal in the direction of most difficult magnetization. More than 10,000 oersteds are required for this purpose at room temperature compared with 600 oersteds for iron and 300 for nickel. At higher temperatures cobalt becomes isotropic, and above 300° C. the hexagonal axis is the direction of most difficult magnetization, all directions at right angles to the axis being equally easy. Magnetization curves for the principal directions at room temperature and at 390° C. are shown in fig. 39.

3. Magnetostriction in Single Crystals.—The magnetostrictive change in length of a single crystal is not the same in all crystallographic directions. This is especially pronounced in iron which expands when the field is applied parallel to a crystal axis [100] and contracts when it is applied parallel to a cube diagonal [111] (fig. 40). In the direction of the face-diagonal [110] the crystal expands in weak fields and contracts in strong fields. Nickel contracts in all field strengths in all directions.

VIII. TEMPERATURE AND THE CURIE POINT

It has been known for many years that when iron reaches a high temperature it loses its ferromagnetism and is no longer strongly

FIG. 41.—EFFECT OF TEMPERATURE ON MAGNETIZATION OF IRON SUBJECTED TO FIELDS OF VARIOUS STRENGTH. MAGNETIZATION DROPS TO LOW VALUE AT CURIE TEMPERATURE, 770° C. (E. M. TERRY)

attracted by a magnet. The temperature at which any ferromagnetic material loses its magnetism is known as the Curie point; it is 770° C. for iron and 358° C. for nickel. In the 1960s the highest known Curie point was 1,120° C., for cobalt. For some materials the Curie point lies near the absolute zero of temperature.

When a magnetic material is subjected to a strong constant field, an increase in temperature brings about a continuously accelerating decrease in induction. At the Curie point the induction comes down abruptly, almost to zero, and the curve is retraced when the temperature is lowered again. Fig. 41 shows this behaviour in iron. On the other

hand when the iron is subjected to a weak field the induction will first increase with temperature and after passing through a maximum will drop to a low value at the Curie point as before.

In iron and in other materials which may be called normal, the initial and maximum permeabilities first increase and then decrease with increasing temperature, and the coercive force and hysteresis loss continually decrease. The characteristic maximum in the initial and maximum permeabilities, just below the Curie point, is associated with the low magnetic anisotropy at this temperature. The way in which the size and shape of the hysteresis loop of iron change as the temperature approaches the Curie point is shown in fig. 42.

Iron and nickel show normal magnetic behaviour with change of temperature. No changes in their crystal structures occur between room temperature and the Curie point. On the other hand such structural changes do occur in many alloys; e.g., the so-called

FIG. 42.—CHANGE IN FORM OF HYSTERESIS LOOP OF IRON NEAR THE CURIE POINT (H. KÜHLEWEIN)

FIG. 43.—CURIE POINT DETERMINED BY CHANGE IN PHASE; AT 980° C., FOR IRON-COBALT ALLOY (A. PREUSSE)

C., and the magnetization (measured in a strong field) drops toward zero precipitously (fig. 43) instead of in the normal fashion as it does for iron (fig. 41).

IX. EFFECT OF MAGNETIZATION ON OTHER PROPERTIES

Aside from producing magnetostriction, magnetization also effects changes in many other properties; and a ferromagnetic material, even though unmagnetized, has properties that are characteristic of its ferromagnetism. The more important of these properties are: (1) electrical resistance; (2) thermal expansion; (3) Young's modulus and other elastic constants; (4) magneto-caloric effect; and (5) specific heat. The resistivity of magnetic materials is affected also by stress; tension may either increase or decrease

FIG. 44.—RESISTIVITY (ρ) OF MAGNETIC MATERIAL (PERMALLOY) INCREASES SLIGHTLY WITH MAGNETIZATION. MOST OF INCREASE OCCURS AFTER MAGNETIZATION IS WELL BEYOND KNEE OF MAGNETIZATION CURVE (L. W. MC KEENAN)

the resistivity, depending on whether the material has positive or negative magnetostriction.

1. Magnetism and Resistivity.—When nickel is magnetized in a strong field, its electrical resistivity is increased by about 2%, and a similar but smaller effect is found in iron. Such changes were first reported by Lord Kelvin in 1851. A larger change in resistivity, as high as 4% to 5%, is shown by iron-nickel alloys with 70% to 85% nickel. The increase in resistivity with field strength for 84 permalloy (fig. 44) illustrates the general rule that most of the change occurs when the magnetization is well beyond the knee of the curve, and suggests that the change in resistivity (like the magnetostrictive change in length) is associated with rotations rather than reversals of domains. There is a close relation

between changes in length and changes in resistivity; these quantities usually have a constant ratio.

Resistivity is abnormally low whenever a material exhibits ferromagnetism. This may be illustrated by comparing the resistivities of nickel and palladium, elements with similar positions in the periodic table. The resistivity-temperature curves (fig. 45) are drawn so that they coincide at a temperature just above the Curie

FIG. 45.—RESISTIVITY OF MAGNETIC MATERIAL IS ABNORMALLY LOW AS LONG AS IT IS FERROMAGNETIC (H. H. POTTER AND J. G. G. CONYBEARE)

point θ of nickel, when both metals are nonmagnetic; the separation of the curves below this temperature indicates ferromagnetic lowering of resistivity. The ferromagnetism becomes progressively weaker as the Curie point is approached, and the separation of the curves in the figure correspondingly diminishes.

2. Magnetism and Thermal Expansion.—The thermal expansion of magnetic materials is so abnormal that occasionally they will contract as the temperature is raised in the vicinity of the Curie point. In some alloys, such as invar, the expansion is very small over a range of temperatures that includes room temperature, a property of great technical importance.

The origin of the abnormal expansion lies in a change in interatomic forces that occurs when the material becomes ferromagnetic. The iron-nickel alloys show these changes in a striking way (fig. 46). As nickel and the alloys with more than 70% nickel cool through the Curie point, the expansion coefficients first increase and then decrease rapidly. In contrary fashion, the coefficients of alloys with 30% to 70% nickel first decrease sharply and then increase. These changes may be regarded as the result of the superposition of a magnetic expansion or contraction on the normal; in invar, which contains about 36% nickel, the anomalous and normal expansions neutralize each other at room temperature.

FIG. 46.—THERMAL EXPANSION CURVES OF MAGNETIC MATERIALS SHOW ANOMALIES NEAR AND BELOW CURIE POINTS (P. CHÉVENARD)

FIG. 47.—SPECIFIC HEAT OF A MAGNETIC SUBSTANCE IS UNUSUALLY HIGH. CURVES FOR NICKEL (E. LAPP) AND COPPER (H. KLINGHART) ARE COMPARED

When the nickel content is about 70%, there is no anomalous magnetic expansion or contraction at any temperature; at this composition the Curie point of these iron-nickel alloys is a maximum.

3. Abnormal Stress-Strain Relation.—In almost all substances a small mechanical stress σ (tension) will produce a strain ϵ (expansion) that is proportional to the stress, as required by Hooke's law

$$\epsilon = \sigma/E$$

in which Young's modulus E is constant. In an unmagnetized magnetic material, however, tension will change the direction of local magnetization (fig. 35), and produce a change in length equal to the magnetostriction of the material. Therefore, when tension is applied to a magnetic material, the whole expansion will be the sum of the normal expansion and the magnetostrictive expansion; consequently Young's modulus will vary with stress and deviations from Hooke's law occur (see ELASTICITY).

In a magnetic material Young's modulus will therefore vary both with the amount of strain and with the intensity of magnetization. The change of E with magnetization has been studied in a variety of materials and may be 10% or larger.

4. Specific Heat and Magnetocaloric Effect.—In comparing the specific heats of nickel and copper at various temperatures (fig. 47) there is an unusual effect in nickel in the neighbourhood of its Curie point. Such a rapid rise and still more rapid drop in the curve, occurring with rising temperature, is characteristic of a ferromagnetic material. In theoretical terms the heat necessary to raise the temperature of a magnetic material like nickel equals that for a similar but nonmagnetic material (e.g., copper), plus the heat necessary to overcome the forces that hold the magnetic moments of neighbouring atoms parallel.

This characteristic specific heat of ferromagnetic bodies occurs whether or not the substance is magnetized in the usual sense. This phenomenon is strong evidence of spontaneous magnetization in certain regions or domains in ferromagnetic materials.

Similar evidence for spontaneous magnetization is supplied by the magnetocaloric effect. At temperatures near the Curie point, strong fields theoretically should increase the spontaneous magnetization, accompanied by a rise in temperature. Experimentally, Weiss and R. Forrer observed increases in temperature of more than 1°C . when a field of 18,000 oersteds was applied to nickel just below its Curie point. The change of spontaneous magnetization with temperature, derived from the data, is in good accord with the theory.

X. MAGNETIZATION IN ALTERNATING FIELDS

In many of their uses magnetic materials are subjected to an alternating field produced by an alternating current in the wire associated with the material. The primary effects of alternating fields are: (1) the effective permeability of the material is reduced; (2) the energy loss in the material is increased; (3) there is a time lag between change in field strength and the corresponding induction; and (4) at ultrahigh frequencies of alternation true permeability is less than at low frequencies. The distinction between effective and true permeability is discussed below.

1. Effect of Eddy Currents.—When the magnetic flux in a conducting medium changes with time an electromotive force is generated, and currents flow within the material. These Foucault currents (or eddy currents) depend on the geometry of the specimen, and on its resistivity and permeability; their direction is always such as to counteract the change in field that produced them (fig. 48). The effect of eddy currents is to prevent the field from penetrating immediately to the interior of the material, and when the applied field is varying continually, as it is in much of the apparatus in which magnetic material is used, the field strength inside the material may never be more than a small fraction of that at the surface. The magnetic induction, therefore, decreases from the surface toward the interior.

FIG. 48.—EDDY CURRENTS IN A SOLID BAR

To avoid this reduction in field strength and resultant decrease in alternating flux, the magnetic cores of transformers and other apparatus are laminated, each lamination being insulated electrically from its neighbour. The flux-carrying capacity of such a lamination depends on the thickness (t in cm.), permeability (μ) and resistivity (ρ in ohm-cm. $\times 10^9$) of the material and on the frequency (f in cycles/sec.) of alternation of the magnetic field. It can be calculated accurately provided that the permeability does not vary with field strength. This capacity for carrying flux can be expressed in terms of the effective permeability $\bar{\mu}$, defined as the ratio of the amplitude of the induction \bar{B} (averaged over the section of the lamination) to the amplitude of the applied field strength H_a . When H_a varies sinusoidally with time, $\bar{\mu}/\mu$ varies with frequency as is shown graphically in fig. 49.

In laminations as commonly used in power transformers, the reduction in permeability is a negligible fraction of 1%. When the frequency is high, $\bar{\mu}/\mu$ is inversely proportional to \sqrt{f} , or

$$\bar{\mu} = \frac{\sqrt{\mu\rho}}{2\pi t} \cdot \frac{1}{\sqrt{f}}$$

In a transformer operating at radio frequencies the constants of the materials used are such that 95% of the true permeability is often lost. At these high frequencies the flux-carrying value of a material of given resistivity and thickness is directly proportional to the square root of its permeability.

2. Energy Losses in Alternating Fields.—Eddy currents in a magnetic material consume power and raise the temperature of the material. The power loss W_e may be calculated with some

FIG. 49.—THEORETICAL CHANGE OF APPARENT PERMEABILITY $\bar{\mu}$, AND ENERGY LOSS W_e , DUE TO EDDY CURRENTS, WITH FREQUENCY $f = \omega/2\pi$ FOR SHEETS OF GIVEN THICKNESS t , PERMEABILITY μ AND RESISTIVITY ρ (OHM-CM. $\times 10^9$)

precision provided that μ does not vary with B ; at low frequencies it is proportional to f^2 . At high frequencies it is proportional to $f^{1/2}$, if the material is always magnetized to the same value of B

$$W_e = \frac{\pi t \bar{B}^2}{\sqrt{\mu p}} \cdot f^{1/2}$$

If the amplitude of the magnetizing current is held constant, the loss is proportional to $f^{1/2}$. The hysteresis loss of a magnetic material at intermediate and high inductions is given approximately by Steinmetz' relation

$$W_h = \eta B^{1.6} f$$

The total loss due to hysteresis and eddy currents at low frequencies may then be written

$$W = W_h + W_e = \eta B^{1.6} f + A B^2 f^2$$

where A can be calculated theoretically under certain conditions, as shown above. This relation is sometimes used for the separation of the total loss (as measured with a wattmeter at a given value of B) into its hysteresis and eddy components.

When apparatus operates at low inductions, as it often does for transmission of the feeble signals used in communication, the energy losses incurred are usually measured with a Maxwell bridge, as described below under XIV. *Measurement of Magnetic Quantities*. The data obtained are the A.C. resistance R in ohms, and the inductance L in henries, of a coil surrounding the material under test. The ratio R/L is characteristic of the magnetic material and is related to the energy losses in ergs/cm.³ by the equation

$$\frac{R}{2\pi f L} = \frac{8\pi \mu W}{B^2}$$

The reciprocal of $R/(2\pi f L)$ is often called the quality factor Q . When the frequency is low, the losses through eddy currents and hysteresis may be separated by plotting $R/(2\pi f L)$ or $R/(\mu L f)$ against frequency. W_h varies as $B^2 f$, W_e varies as $B^2 f^2$ and

$$\frac{R}{\mu L f} = a B + c + e f$$

in which a and e respectively are called the hysteresis and eddy current constants, and c is a constant representing an energy loss of unknown origin, important only at very low inductions.

At moderately high frequencies and low inductions the losses in a material of high permeability usually result predominantly from eddy currents. These can be calculated as described above and for them $R/(2\pi f L)$, or $1/Q$, is shown by the curve of fig. 49.

3. *Effects at High Frequencies*.—In considering the effect of frequency on permeability it has been assumed that the permeability μ is independent of frequency and that only the effective permeability $\bar{\mu}$ diminishes as the frequency increases. However, at very high frequencies, of the order of 10^8 to 10^{10} cycles/sec., the permeability decreases to a small fraction of its value at low frequency. This decrease results primarily from the energy losses associated with rapid changes in magnetization. The losses stem from factors other than eddy currents, and may be associated, for example, with the bending of domain walls.

Experiments on ferromagnetic resonance at high frequencies have clarified the nature of the magnetic carriers and the forces between them, and have led to important applications of magnetic materials, especially the ferrites. The principle of the experiments and the experimental arrangements are as follows:

Imagine an electron traveling

FROM "RECENT ADVANCES IN PHYSICS," N. H. SHAMOS & G. M. MURPHY (ED.), BY COURTESY OF NEW YORK UNIVERSITY PRESS, 1956

FIG. 51.—ELECTROMAGNET WITH SECTION OF WAVE GUIDE SHOWING CAVITY USED FOR FERROMAGNETIC RESONANCE. HERE λ IS THE WAVE LENGTH OF THE MICROWAVES THAT EXCITE THE MAGNETIC FIELD H_{rf}

in an orbit and suspended in space as shown in fig. 50. The magnetic moment produced by the orbital motion and spin of the electron can be represented by the vector M . Antiparallel to M is the vector J , which represents the angular momentum of the electron. If a magnetic field H is applied as indicated, the vectors M and J will precess with the frequency $MH/(2\pi J)$.

Now apply a small-amplitude alternating field H_{rf} with a direction perpendicular to H and a frequency equal to or near the precession frequency. The amplitude of the precessing magnetic moment will increase because it is continually pulled by the alternating field, until a final amplitude is reached which depends on the internal damping or energy loss associated with the precession. The amplitude of the magnetic moment obtained with a given alternating field is measured; by varying the frequency of H_{rf} until the amplitude is a maximum (at resonance) the natural frequency of precession and the ratio M/J can be determined. The results of the experiments give fundamental information concerning the nature of the magnetic dipoles and the forces acting on them in the solid state.

One way of observing resonance at microwave frequencies (see ELECTROMAGNETIC WAVES) is indicated in fig. 51. A wave guide is terminated at one end by a cavity one wave length long, and a small spherical specimen is supported at the centre of the cavity by a polystyrene rod. Under these conditions the alternating field, obtained by excitation of the wave guide, is perpendicular to the constant field H of several thousand oersteds which is supplied by an electromagnet. By measuring the standing wave pattern in the wave guide the effective permeability of the specimen, and in particular the maximum permeability at resonance, can be determined. The results of an experiment in which supermalloy was excited at 24,000 mc./sec. is shown in fig. 52. The position and sharpness of the peak give basic information about the gyromagnetic properties of the atoms and their interaction.

F. F. Roberts observed that if a piece of magnetized magnesium ferrite is placed in a microwave transmission line the plane of polarization of the wave is rotated through a large angle, e.g., 90° or 180° , the amount of rotation (Faraday rotation) being governed by the intensity of magnetization of the ferrite. In manganese ferrite rotations of 90° to 180° can readily be observed. A device constructed on this principle by C. L. Hogan permits microwave transmission in one direction without appreciable loss but substantially prevents transmission in the opposite direction. Such a device can be used to prevent unwanted reflections in a transmission

line, and similar devices can be adapted for many kinds of micro-wave switching.

4. Time Lag in Magnetization.—As already mentioned, eddy currents delay magnetization so that after a sudden change in H from one value to another, a perceptible time elapses before B reaches its final corresponding value. Another factor involved in this lag is metallurgical aging. This is usually observed in permanent magnets, the induction in which can be observed to change over a period of years, and is attributed to the slow precipitation of metallic phases from supersaturated solution at room temperature. Similar changes occur in ordinary annealed iron to an extent that the coercive force may eventually be doubled even though the material has not been heated above 100°C . Materials that have been severely cold-worked sometimes become magnetically softer as a result of slow relief of internal strains.

A more rapid change of induction with time has been observed repeatedly since Ewing's experiments of 1885. One method of experimenting is to change H suddenly, then observe the change in B with time. Another way is to measure the permeability at very low inductions, at various times after demagnetizing and after the measuring current has been applied. Such changes are associated with the impurities present, and disappear after purification at a high temperature in hydrogen. It has been suggested that the diffusion of traces of nitrogen or oxygen in iron will so impede the movement of domain boundaries as to account for the observed changes of permeability with time.

XI. DIAMAGNETISM

Faraday showed in 1845 that all substances may be classified as diamagnetic and paramagnetic (he felt ferromagnetism was a kind of paramagnetism). He distinguished between the paramagnetism and diamagnetism of feebly magnetic substances by suspending them in a strong inhomogeneous field and noting whether they were drawn into or repelled from the strongest part of the field. The force with which a diamagnetic material is repelled by a field is proportional to the strength H and gradient dH/dx of the

field, and to the susceptibility κ and volume v of the material

$$f = \kappa v H dH/dx$$

The susceptibilities of solid diamagnetic substances are usually about -1×10^{-6} or -2×10^{-6} , and are normally independent of field strength. Bismuth has the exceptionally large value of -13×10^{-6} , but even this is millions of times less than that of the ferromagnetic metals. Bismuth is also exceptional in that its susceptibility varies with the field at low temperatures (50°K).

While diamagnetic and paramagnetic materials have little practical use, a study of their behaviour is very important for an understanding of the nature of matter. Diamagnetism is an atomic property, and usually occurs when the atom has a symmetrical electronic structure and no permanent magnetic moment. In discussing diamagnetism it is appropriate to use the term atomic susceptibility defined as $\chi_A = \kappa A/d$, where A is the atomic weight and d is the density. Then $\chi_A H$ is the magnetic moment of one gram atomic weight; divided by Avogadro's number it is the average magnetic moment per atom resolved parallel to the magnetic field. Similarly $\chi_M = \kappa M/d$ is the molecular susceptibility, where M is the molecular weight.

As P. Curie showed in his classical researches (1895), diamagnetism is usually independent of temperature, and so is not disturbed markedly by atomic collisions or the positions of nearby atoms. However, some change in the diamagnetic susceptibility is generally noted when a substance changes from the solid to the liquid state.

Following the work of Curie, in 1910 and 1912 K. Honda and M. Owen reported measurements of the susceptibilities of many elements. Fig. 53 shows the atomic susceptibilities as dependent on atomic number according to more recent data summarized by P. W. Selwood. Here it is apparent that the rare-earth metals are strongly paramagnetic, that the metals of the transition groups containing palladium and platinum are rather strongly paramagnetic and that most good metallic conductors of electricity are weakly paramagnetic. This implies what is in fact the case, that in a metal the conducting electrons are paramagnetic. The other metals and the nonmetals are usually weakly paramagnetic or diamagnetic.

Most ionic and molecular compounds are also diamagnetic because their electrons are paired and their permanent moments tend to cancel each other; however, gaseous oxygen (O_2) is paramagnetic. Fig. 54 shows the atomic or molecular susceptibilities of some typical materials and the way they change with temperature.

1. Theory.—Modern understanding of the origin of diamagnetism.

FIG. 53.—ATOMIC SUSCEPTIBILITIES OF THE ELEMENTS AT ROOM TEMPERATURE. DOTTED LINES CONNECT ALKALI METALS (PARAMAGNETIC) AND RARE GASES (DIAMAGNETIC)

FIG. 54.—VARIATION OF ATOMIC OR MOLECULAR SUSCEPTIBILITY WITH TEMPERATURE FOR SOME REPRESENTATIVE MATERIALS

Susceptibilities of diamagnetic and weakly paramagnetic substances are normally independent of temperature; those of strongly paramagnetic substances decrease with increasing temperature

tism is due largely to Langevin, who published his celebrated paper on magnetism and electron theory in 1905. He considered an atom with a single electron of charge e and mass m traveling with velocity v in a circular orbit of radius r (fig. 55). This current gives rise to a magnetic moment M that is proportional to the current and the area of the orbit

$$M = \frac{ve/c}{2\pi r} \cdot \pi r^2 = \frac{ve r}{2c}$$

where c is the velocity of light. As pointed out by Sir Joseph Larmor, application of a magnetic field H will create an electromagnetic force in the orbit, as a result of the flux threading it, and this will cause the electron to change velocity by

$$\Delta v = -\frac{eHr}{2mc}$$

in such a direction as to change the moment M by

$$\Delta M = \frac{er\Delta v}{2} = -\frac{e^2 H r^2}{4mc}$$

The susceptibility of this atom is then $-\Delta M/H$, and the susceptibility of one gram atomic weight is

$$\chi_A = -\frac{Ne^2 r^2}{4mc^2}$$

where N is the number of molecules in a gram molecular weight. If an atom has many electron orbits, oriented in all directions with respect to the field, the atomic susceptibility becomes

$$\chi_A = \frac{Ne^2 \Sigma r^2}{6mc^2} = -2.83 \times 10^{10} \Sigma r^2$$

in which the mean square orbital radius is summed over all the orbits.

The last equation, Langevin's equation of diamagnetism, applies to every diamagnetic or paramagnetic substance. If an atom has a permanent moment and the material is consequently paramagnetic or ferromagnetic, its susceptibility still has the diamagnetic component given by this equation.

Knowing the number of electrons in the atom, one may calculate from the diamagnetic susceptibility the average (root mean square) radius of an atom and compare this with the radius determined by other means. Values so obtained are consistent with present knowledge of atomic structure.

In quantum mechanics (*q.v.*) the Langevin formula still holds when the field of the nucleus is spherically symmetrical, as it is in atoms or ions. The meaning of the orbital radius r , however, is somewhat different, since the electrons are assumed to be distributed in less localized orbits. Calculation of diamagnetic susceptibilities by wave mechanics has been attempted for a number of the simple atoms and molecules and has been moderately successful for the rare monatomic gases helium, neon, argon, krypton and xenon, and for molecular hydrogen (H_2). For helium, theory indicates an atomic susceptibility ($\times 10^6$) of 1.65 to 1.90, depending on the method of calculation; G. G. Havens' empirical value is 1.91. For hydrogen the calculated and observed values respectively are 2.10 and 2.01. For the other elements listed, both theoretical and measured susceptibilities vary over a greater range.

Positive ions of the alkali and alkaline-earth metals and of the halogens have the rare gas structure and can also be treated theoretically. The lack of precision in calculation arises in the approximate nature of wave functions and the effective molecular charge assumed.

2. Compounds.—Most salts are diamagnetic because their ions (*e.g.*, Na^+ and Cl^-) have completed electron shells characteristic of the rare gases and consequently have no permanent magnetic moment. The susceptibilities of the separate ions can be deduced from a series of measurements on solid salts or solutions. There is some ambiguity in separating the susceptibility of the salt into its component parts, and there is also some change with concentration and state of aggregation, but each ion has a value of χ_A that is approximately constant. The observed increase of χ_A with the number of electrons n is to be expected according to simple theory. In ions with the same number of electrons but a different nuclear charge, as in the series I^- , Xe , Cs^+ and Ba^{2+} , diamagnetic susceptibility decreases numerically with increasing charge because the larger charge draws the electrons closer to the nucleus and so diminishes the value of Σr^2 in Langevin's equation.

FIG. 55.—ELECTRON VELOCITY

Velocity of electron is changed by application of field H so that induced magnetic moment is in direction opposite to that of field

The principle of additivity of the diamagnetism of ions may be extended to include also the more complex ions NO_3^- , SO_4^{2-} , PO_4^{3-} , NH_4^+ and others. Values for these are less certain than those for the simple ions already considered.

In his early comprehensive experiments (1908-13) P. Pascal found the molecular susceptibility of many organic compounds to be the sum of the susceptibilities of the atoms composing them, plus additional terms characteristic of the various bonds occurring in the molecule.

While the Langevin theory is not very illuminating for a simple diatomic molecule like H_2 , quantum mechanics can be used provided that the wave functions are known with sufficient accuracy. In the expression for χ_M there is a term, always positive, added to the negative term of the Langevin equation.

Van Vleck and N. H. Frank used the wave functions of molecular hydrogen to calculate both terms and found them to be -4.66×10^{-6} and $+0.51 \times 10^{-6}$. The net result of -4.15×10^{-6} may be compared favourably with the experimental values ranging from about -3.9 to -4.0×10^{-6} .

Calculation for heavier diatomic molecules cannot be performed so rigorously, and the approximate wave functions generally used for these substances give too high a value of χ_M . Knowledge of gases is also limited by the difficulty in making measurements with accuracy.

XII. PARAMAGNETISM

The paramagnetic susceptibility of materials examined by Curie decreased with increasing temperature. Subsequently a large class of weakly paramagnetic substances was found for which the susceptibility is practically independent of temperature (fig. 54); this class includes many of the metallic elements only when they are in the solid conducting state, and when the paramagnetism results from the conduction electrons. This is called weak paramagnetism; by contrast, strong paramagnetism depends on a permanent magnetic moment of the component atoms or molecules.

The origin of the two kinds of paramagnetism is shown schematically in fig. 56, where the curved lines represent electron

FIG. 56.—PARAMAGNETISM OCCURS WHEN INNER SHELL IS INCOMPLETE (HEAVY LINE) AND THEREFORE HAS PERMANENT MOMENT (STRONG PARAMAGNETISM), OR WHEN ELECTRONS OF OUTER SHELL (BROKEN LINE) BECOME CONDUCTION ELECTRONS IN METAL (WEAK PARAMAGNETISM)

shells in an atom. The outer line is broken to indicate that the electrons in this shell are loosely bound and become conduction electrons in a solid metal, or valence electrons in a compound. In a metal the spins of some of these electrons can be changed by an applied field in a way that can be explained by quantum mechanics, and can produce weak paramagnetism as in metallic sodium. Most of the other shells have their full complement of electrons, and the magnetic moments from their orbital and spin motions are self-neutralizing; thus they contribute only diamagnetism to the atom. On the other hand some of the shells in some atoms are incomplete and therefore have a large resultant moment compared with the spin of the conduction electrons or the diamagnetic moment of the closed shells. Such incomplete shells occur notably in the iron and rare-earth, palladium and platinum groups, and all show strong paramagnetism. In the extreme cases of the rare-earth elements dysprosium and holmium, the fourth shell electrons have spin and orbital moments that combine to give the largest magnetic moment of any atoms.

Before discussing the experimental results further it is desirable to outline the classical and quantum theories of strong paramagnetism, and the quantum theory of weak paramagnetism.

1. Langevin Theory.—Curie's measurements at various temperatures could be expressed by the law now known by his name

$$\chi_M = C_M/T$$

in which T is the absolute temperature and C_M the Curie constant characteristic of the substance. The classical theory of this kind of paramagnetism was developed by Langevin who investigated mathematically the behaviour of an ensemble of magnetic dipoles, each of moment μ_M , in a field of strength H . The effect of the field is to produce alignment, while thermal agitation tends to destroy alignment. Assuming that the molecules are so far apart that their mutual forces can be neglected, the energy due to the field is

$$W = \mu_M H \cos \theta$$

for each dipole so oriented that its moment μ_M makes the angle θ with H . If the ensemble is subject to thermal agitation, the Boltzmann equation from statistical mechanics ($q.v.$) shows that at any temperature T the number of dipoles oriented in the solid angle $d\omega$ about the direction θ is proportional to

$$e^{-W/kT} d\omega = e^{(\mu_M H \cos \theta)/kT} d\omega$$

For all the molecules the average value of the moment in the direction of the field $\bar{\mu}_M$ is calculated, and its ratio to the total moment, or to the moment present when all magnets lie parallel, is found to be

$$\frac{\bar{\mu}_M}{\mu_M} = \text{ctnh} \frac{\mu_M H}{kT} = \frac{kT}{\mu_M H}$$

This is Langevin's equation of paramagnetism. At ordinary temperatures $\mu_M H < kT$, and this equation may be expanded in series form

$$\frac{\bar{\mu}_M}{\mu_M} = \frac{\mu_M H}{3kT} - \frac{1}{45} \left(\frac{\mu_M H}{kT} \right)^3 + \dots$$

The moment of a gram molecule is $N\bar{\mu}_M$ and the molecular susceptibility is then $\chi_M = N\bar{\mu}_M/H$; thus at ordinary temperatures, for which the first term of this equation is sufficient

$$\chi_M = \frac{N\bar{\mu}_M}{H} = \frac{N\mu_M^2}{3kT} = \frac{C_M}{T}$$

This is Curie's law, with the Curie constant given by

$$C_M = N\mu_M^2/3k$$

Thus Langevin's work explained Curie's law and showed how the moment per molecule could be determined from experiment.

2. Quantum Theory.—Quantum theory has fundamentally changed concepts of atomic structure and revised the interpretation of paramagnetic phenomena in several ways:

1. Langevin assumed that any orientation of magnetic moment with respect to an applied field is possible; quantum theory requires that only discrete changes of angular momentum are possible, imposing restrictions on the orientations of magnetic moment. As a result the Langevin equation of paramagnetism is replaced by a more complicated expression. In the simplest case of an atom with a single electron that is free to change its direction of spin the only two possible orientations are those parallel and antiparallel to the field, and the function becomes

$$\bar{\mu}_M/\mu_M = \tanh(\mu_M H/kT) = \mu_M H/kT + \dots$$

the last part being applicable when H/T is not too large. When many orientations are possible the function approaches Langevin's equation as a limit.

2. There is a natural unit for magnetic moment, the Bohr magneton, substantially equal to the moment of one electron spinning about its own centre. Its value is

$$\beta = eh/4\pi mc = 9.27 \times 10^{-21} \text{ erg/gauss}$$

Here e is the charge and m the mass of the electron. h is Planck's constant and c the velocity of light. It is convenient to convert susceptibility data to the apparent number of Bohr magnetons per atom, by dividing the moment per atom (determined from Langevin's expression for the Curie constant) by β . This is called the effective Bohr magneton number: $\mu_{eff} = \bar{\mu}_M/\beta$. In terms of the Langevin theory it may be expressed

$$\mu_{eff} = \frac{\bar{\mu}_M}{\beta} = \sqrt{\frac{3k\chi_M T}{N\beta^2}} = 2.83\sqrt{\chi_M T} = 2.83\sqrt{C_M}$$

and can be calculated if enough is known of the structure of the atom.

3. The effective moment of an atom may change with temperature or field strength in a calculable way, in which case Curie's law will not hold. Under certain conditions χ_M will be of the form

$$\chi_M = \frac{N\mu_M^2}{3kT} + Na$$

Such an expression, with the constant α included, accounts quantitatively for the behaviour of some of the rare-earth ions, and applies in principle in other cases for which it cannot often be worked out in detail.

4. The temperature-independent or weak paramagnetism of many metals (fig. 54) and of some conducting oxides and salts was quite inexplicable with classical theory. Quantum theory, however, provides an explanation by showing that conduction electrons, behaving as an electron gas, have just this observed character.

The applications of these concepts to substances of various types will now be considered.

3. Rare Earths.—The ions of the rare-earth elements cerium (atomic number 58) to ytterbium (atomic number 70) are good examples of strongly paramagnetic substances. The permanent magnetic moment is due to the 4f electron subshell in the usually trivalent ions. This fourth shell is protected by the outer shells from the influence of neighbouring atoms and so the assumptions underlying the theory are fairly well satisfied (*see* ATOM; PERIODIC LAW).

Ionic susceptibilities are deduced from measurements on solutions, solid salts and oxides by subtracting the contributions of water and other ions. The susceptibilities decrease with increasing temperature, as expected, except that χ_M for the samarium ion Sm^{3+} is almost constant above room temperature and Eu^{3+} shows an almost constant susceptibility at low temperatures.

Calculation of the susceptibilities of the rare-earth ions by quantum mechanics is one of the important successes of the Van Vleck theory (fig. 57), based on the earlier work of F. Hund. Both terms of the last equations above, those dependent on and independent of

FIG. 58.—EFFECTIVE MOMENT OF IONS OF IRON GROUP OF ELEMENTS, PLOTTED AGAINST NUMBER OF ELECTRONS IN ION. VERTICAL LINES INDICATE RANGE OF OBSERVED VALUES, CONNECTING LINES INDICATE THEORETICAL VALUES BASED ON DIFFERENT ASSUMPTIONS

4. Ions of the Iron Group.—Strong paramagnetism occurs also in the ions of the elements lying between scandium and copper, and is most marked for manganese, iron and cobalt. The moments of the ions are generally less than those of rare-earth ions, because the shell responsible for the paramagnetism is smaller and has only 10 instead of 14 electrons when filled.

In calculating the moments from quantum theory the method used for the rare earths is not at all successful, as shown by the broken line of fig. 58. Results of calculations made with other assumptions are shown by the solid lines (a) and (b); the observed values lie between these curves. Stoner has indicated the reason for this. The outermost shell of the ion is responsible for the moment and is subject to the influence of surrounding ions. Their effect on the orbital motions is difficult to calculate, but if the effect is severe only the spin moments will be influenced by the magnetic field, and curve (a) results. On the other hand if interaction with neighbouring ions is weak, orbital motions will be affected and curve (b) is calculated; here the further assumption is made that the energy of thermal agitation can change the distribution of electron spins in the unfilled shell, an assumption consistent with modern knowledge of the structure of these ions. When the influence of surrounding ions on the unfilled shell is moderate, the empirical ionic moments may be expected to lie between the two theoretical limits; in fact they do.

5. Paramagnetism at Low Temperatures.—At ordinary temperatures the Langevin equation may be represented with sufficient accuracy by the first term of the series expansion noted above. However, at low temperatures and in strong fields $\mu_M H/kT$ may be so large that the complete equation, or its quantum equivalent, must be used. Under these conditions the susceptibility is no longer independent of field strength, and the magnetic moment of the material approaches a limiting value corresponding to alignment of the molecular magnets parallel to the field.

The first experimental test of this phenomenon was carried out at temperatures as low as 1.3° K. and field strengths up to 22,000 oersteds; the results confirmed the theory in a satisfactory manner. A slightly different relation was predicted by quantum theory, and has been verified entirely within the limits of accuracy of validating experiments.

The magnetic behaviour of certain paramagnetic salts is important in producing very low temperatures. A temperature just 0.0014° above absolute zero was reached in 1951 using the paramagnetic salt chrome aluminum alum. By the 1960s temperatures even closer to absolute zero were being obtained with the aid of nuclear magnetization (*see* LOW-TEMPERATURE PHYSICS).

6. Paramagnetic Gases.—Most monatomic gases, such as those in group VIII, the rare gases (*see* CHEMISTRY), are diamagnetic because with complete electron shells they have no re-

FIG. 57.—EFFECTIVE MOMENT OF THE TRIVALENT IONS OF THE RARE EARTH ELEMENTS AT ROOM TEMPERATURE. BROKEN LINE SHOWS VALUES CALCULATED BY VAN VLECK THEORY

temperature, were derived quantitatively from theory, and the unusual change of χ_M with temperature for samarium and europium were satisfactorily explained.

Rare earths in metallic form have large susceptibilities, and the elements from gadolinium to thulium are ferromagnetic at low temperatures. Above the Curie points important deviations from Curie's law are observed, and a law of the form

$$\chi_A = C/(T - \theta)$$

is closely followed. This is the Curie-Weiss law for many paramagnetic solids, particularly those in which the magnetic cores of the atoms are under the influence of magnetic or electric fields of nearby atoms, and the Langevin assumptions therefore are not satisfied. For gadolinium, as for the other ferromagnetic elements, θ is approximately the Curie point, but the appearance of θ in the Curie-Weiss equation does not mean necessarily that the material will be ferromagnetic below the temperature $T = \theta$; rather, the law breaks down before this point is reached.

sidual magnetic moments. Metal vapours, however, have monatomic molecules in which the single electron in the outer shell should give rise to paramagnetism. Measurements on such vapours are difficult, but potassium and thallium are reported to be paramagnetic; potassium obeys Curie's law over a limited range of temperatures and has a susceptibility, according to rather inaccurate measurements, corresponding approximately to a single uncompensated electron ($\chi_M = 0.375/T$).

Molecules that have more than one atom are generally diamagnetic because they contain an even number of electrons with moments that neutralize each other. A well-known exception to this rule is oxygen (O_2). This gas follows Curie's law ($C_M = 1.00$) except at high pressures when the Curie-Weiss law is obeyed, with the constant θ being small and negative. Liquid oxygen also follows the Curie-Weiss law, and the susceptibility increases with decreasing temperature through the solidification point.

The molecular susceptibility of nitric oxide has been measured from 20° to -160° C. (below its normal boiling point), and the effective Bohr magneton number μ_{eff} has been found to vary by about 15% over this range of temperature. Accurate calculation of μ_{eff} and its variation with temperature was carried out by Van Vleck, who based his work on the electronic structure derived from spectroscopic data. The close agreement between calculated and observed values tends to validate the theory.

7. Paramagnetism of Free Electrons.—The weak temperature-independent paramagnetism of many of the metals (fig. 53 and 54) was inexplicable in terms of the Langevin theory, according to which all paramagnetism should decrease as temperature rises. According to modern theory the conduction electrons of a metal have spin moments that can be oriented slightly by a magnetic field. In the simplest case, with one free electron per atom, quantum theory predicts an atomic susceptibility of $1.83 \times 10^{-6} (A/d)^{2/3}$, where A is the atomic weight and d is the density in g./cm.³; a smaller diamagnetism, also predicted by quantum theory, is equal to one-third the paramagnetic contribution when the electrons are free.

In actuality the electrons of metals are not wholly free but are partially bound to the atoms, and are influenced by so-called correlation and exchange forces that are quantum mechanical in nature. Also, the ionic core of the atom makes an important diamagnetic contribution to the susceptibility. The various components have been calculated for sodium, and when summed they come within about 10% of the observed susceptibility. For other elements the calculations are less satisfactory.

The paramagnetic contributions of the electrons will vary with the nature of the metal and the diamagnetism of the ionic cores will vary for different atoms; qualitatively, it is clear that such factors will make some metals weakly paramagnetic while others will be weakly diamagnetic. The order of magnitude of the susceptibility is explained by theory; more exact calculations await further quantitative development of atomic theory.

8. Ferromagnetic Materials Above the Curie Point.—All materials that exhibit ferromagnetism are paramagnetic when they are heated above the Curie temperature. As temperature continues to increase, the susceptibility decreases continually according to the Curie-Weiss law for strongly paramagnetic substances, unless there is a change in the phase structure of the material. If the Curie-Weiss law were followed exactly, a straight line would result when $1/\chi_A$ is plotted against temperature. The data for iron, cobalt and nickel show some variations from the expected linear relations. Definite breaks in the curve for iron result from changes in its crystal structure at 910° and 1400° C.

One should be able to calculate from the slope of each of these lines the magnetic moment per atom, and to compare this with the moment calculated from the saturation magnetization found at lower temperatures when the material is ferromagnetic. For nickel the ferromagnetic moment is 0.61 Bohr magnetons per atom, and the moment calculated from the Curie constant is 1.6 in the same units. Similar discrepancies occur for iron and cobalt. These results show that there is not an integral number of electron spins per atom; therefore the atoms will not all have the same moment at any instant. This means that the calculation of mag-

netic moment from the Curie constant cannot properly be made by the relation used and that modifications of the theory are necessary.

9. Paramagnetic Resonance.—Experiments on resonance at high (microwave) frequencies are made in the same way for paramagnetic substances as for ferromagnetic materials, described above (*X. Magnetization in Alternating Fields*; fig. 50-52). Resonance occurs when the frequency of the field is

$$f = MH/(2\pi J)$$

where H is the strength of the steady magnetic field and M and J are the magnetic and mechanical moments of the atom (see fig. 50). This may also be written

$$f = g\beta H/h$$

where β is the Bohr magneton, h is Planck's constant, and g represents the spectroscopic splitting factor which is 2.00 for electron spin and 1.00 for the orbital motion of the electron.

In solids the electron orbits in a given atom are generally fixed by the strong electrostatic fields of neighbouring atoms so that only the spin moments of the electrons can precess in an applied magnetic field. However, the coupling between spin and orbital motion prevents the spin from being perfectly free, and g departs from the value 2.00. The amount of departure gives information about atomic forces and interactions in the solid state, and is a specific property of the material.

In a crystal the spin-orbit coupling depends on the direction in which the steady magnetic field is applied with respect to the crystal axes. Consequently g values found for differently oriented fields also give valuable information about the fields of force in solids.

The atomic nucleus itself may have a magnetic moment, expressed in nuclear magnetons which are smaller than Bohr magnetons by a factor of 1,840. Nuclear moments precess in a magnetic field, and nuclear magnetic resonance is quite analogous to paramagnetic resonance. The data obtained are useful in studying nuclear structure and in reaching low temperatures, as discussed above.

10. Antiferromagnetism.—There is a class of materials that are paramagnetic as judged by their small positive susceptibility; their behaviour is interpreted in terms of a negative molecular field, or the tendency of neighbouring atomic magnets to be arranged antiparallel. This is illustrated in fig. 7(C). A typical member of this class is manganous oxide (MnO) for which the susceptibility is plotted against temperature in fig. 59. The temperature of the susceptibility maximum is called the antiferromagnetic Curie point or the Néel point; below this temperature there is antiparallel arrangement but above it the thermal agitation destroys the regular arrangement of atomic moments and the material behaves like a normal paramagnetic substance (fig. 7[A]).

The spatial orientations of the atomic moments have been determined for a number of antiferromagnetic substances with the aid of neutron diffraction. Some of the best-known antiferromagnetic materials are chromium, copper chloride, ferrous fluoride

FIG. 59.—SUSCEPTIBILITY OF MnO AS DEPENDENT ON TEMPERATURE. TYPICAL OF ANTIFERROMAGNETIC SUBSTANCE. TEMPERATURE OF MAXIMUM IS NÉEL POINT (H. BIZETTE, C. F. SQUIRE, B. TSAI)

manganous oxide and nickel oxide; hundreds of others are known. Néel points are known to vary from less than 1° to 800° above absolute zero.

In these materials the force that produces the antiparallel arrangement between the atomic moments (e.g., between Mn ions in MnO) generally is the quantum mechanical force of exchange that acts from one magnetic atom (Mn) through the intermediate nonmagnetic atom (O) to the next magnetic atom. Such indirect action has been designated by H. A. Kramers as superexchange.

Antiferromagnetic materials form domains in much the same way as ferromagnetic materials. Such a formation, including one wall, is shown schematically in fig. 60.

XIII. THEORY OF FERROMAGNETISM

One requirement of a ferromagnetic material is that its atoms have permanent magnetic moments. The magnetic moment of an atom comes from its electrons, since the nuclear contribution is negligible. An electron has a magnetic moment because of its spin, and may have an additional moment from its orbital motion.

Another requirement of ferromagnetism is some kind of interatomic force that keeps the magnetic moments of many atoms parallel to each other. Without such forces the atoms would be disordered by thermal agitation, the moments of neighbouring atoms would neutralize each other, and the large magnetic moment characteristic of ferromagnetic material would not exist. The material would then be merely paramagnetic.

Current knowledge of these interatomic forces and of the structure of the atom permits a general description of the origin of ferromagnetism. The following steps in the theory may be enumerated: (1) the ultimate magnetic particle is the spinning electron, and a change in magnetization fundamentally results from a change in the directions of spin of certain electrons, not to any appreciable extent from a change in their orbital motions; (2) in iron, cobalt and nickel the electrons responsible for ferromagnetism lie in the incomplete third atomic shell; in the rare earths they are in the fourth shell. In complete shells the electrons are arranged symmetrically so that the spins neutralize one another and the combined moment is zero; and (3) in ferromagnetic materials the spins of neighbouring atoms are held parallel by strong quantum mechanical forces, whereas in the atoms of other substances the forces usually tend to make the spins of neighbouring atoms antiparallel and self-neutralizing. The circumstances under which these quantum forces effect parallel orientations and form ferromagnetic domains, or antiparallel orientations that lead to paramagnetism or antiferromagnetism, will be discussed in the following paragraphs. Before considering these steps in modern theory in detail, however, it is appropriate to recall the earlier theories and their development.

1. Early Theories.—Ewing was one of the first to attempt to explain ferromagnetic phenomena in terms of interatomic forces. He assumed as did Weber that each atom was a permanent magnet free to turn in any direction about its centre. Neighbouring atoms were assumed to be held parallel by the usual magnetic forces known from large-scale bar magnets. The I, H curve and hysteresis loop were calculated for a linear group of such magnets and were determined experimentally from models with as many as 130 magnets arranged at the points of a plane square lattice. The calculations for a linear chain show that as field strength is gradually increased from zero there is at first a slow continuous rotation of all the magnets together, then sudden change in orientation and finally a further continuous rotation until the magnets

lie parallel to the field. The I, H curves calculated for such a group of magnets resemble in general form the actual curves of iron; they show permeability first increasing, then decreasing, as well as saturation and hysteresis.

G. S. Mahajani calculated the magnetic potential energy of a group of magnets arranged spatially in the same way as iron atoms in a crystal. In agreement with Ewing's theory the magnets tend to be parallel, and some directions in the space array are more stable or preferred than others. On the other hand present knowledge of the structure of atoms and crystals makes it clear that such magnetic forces between atoms are not large enough to keep the magnetic moments of neighbouring atoms parallel, as they must be for ferromagnetism to exist. Such weak forces would readily be disturbed by the thermal motion of atoms at room temperature and even at a few degrees above absolute zero.

It is now well established that very powerful forces, not contemplated when Ewing made his model and proposed his theory, keep the dipole moments of neighbouring atoms parallel. These are the electrostatic forces of exchange which will be discussed in connection with the quantum theory.

2. Molecular Field Theory.—To understand how atomic forces produce ferromagnetism it is desirable to review Weiss's theory of ferromagnetism, which introduces a so-called molecular field that presently will be identified with these forces. Using an approach different from Ewing's, Weiss did not try to explain the nature of interatomic forces but treated them empirically by assuming that they exerted a powerful effect that supported the applied field in lining up atomic moments. This is an extension of Langevin's theory of a paramagnetic gas, which culminated in a formula relating the magnetization I to the field strength H and the temperature T : the hyperbolic cotangent law

$$\frac{I}{I_0} = \text{ctnh} \frac{\mu_A H}{kT} - \frac{kT}{\mu_A H}$$

noted in *XII. Paramagnetism* above. In deriving this, it is assumed that the elementary magnets, each of moment μ_A , are subject to thermal agitation and momentarily may have any orientation to the direction of the field, and that they are too far apart to influence each other. Quantum theory alters the first assumption by stating that in such an ensemble of elementary magnets (atoms) there will be only a limited number of possible orientations, in the simplest case only two, one parallel and the other antiparallel to the direction of the field. In this case the equation corresponding to Langevin's is

$$\frac{I}{I_0} = \tanh \frac{\mu_A H}{kT}$$

Weiss assumed that in a ferromagnetic material a molecular field exists proportional to the intensity of magnetization, and reinforces the magnetic field already present. He therefore replaced the H of Langevin's equation by $H + NI$, calling N the molecular field constant. The resulting equation

$$\frac{I}{I_0} = \tanh \frac{\mu_A (H + NI)}{kT}$$

is perhaps the most important in the theory of ferromagnetism. It indicates that even in zero field there is still considerable magnetization, provided that the temperature is not too high. Putting $H = 0$ and $\theta = \mu_A NI_0/k$, this equation reduces to

$$\frac{I}{I_0} = \tanh \frac{I/I_0}{T/\theta}$$

This purports to specify the magnetization at zero applied field by the same fraction for all materials, when the magnetization is expressed as a fraction of its value I_0 at absolute zero and the temperature is given as a fraction of the Curie temperature θ on the absolute scale. This magnetization-temperature relation, plotted as the upper solid line of fig. 61, means that at all temperatures below θ the intensity of magnetization has a definite value even when no field is applied.

According to this idea the I of the last equation represents the

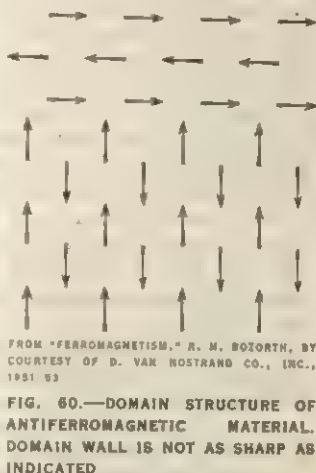

FIG. 60.—DOMAIN STRUCTURE OF ANTIFERROMAGNETIC MATERIAL. DOMAIN WALL IS NOT AS SHARP AS INDICATED

FIG. 61.—SATURATION MAGNETIZATION AS DEPENDENT ON ABSOLUTE TEMPERATURE IN RELATIVE UNITS. SOLID CURVES ARE THEORETICAL, FOR CLASSICAL (WEISS) AND QUANTUM THEORIES

magnetization of a domain, and is determined experimentally by measuring the magnetization of a specimen when all domains are parallel; *i.e.*, at saturation ($I = I_0$). This equation should then be written

$$\frac{I}{I_0} = \tanh \frac{I_0/I_0}{T/\theta}$$

However, a piece of iron may be apparently unmagnetized at room temperature. Weiss explained this by formulating the domain theory described above, according to which each part of a ferromagnetic material is magnetized to saturation, the magnetic moments of the separate parts being oriented in different directions to produce an over-all effect of zero.

These relations are also important for ferromagnetic materials above the Curie point, when they are paramagnetic. Then I is small compared to I_0 and

$$\frac{I}{I_0} = \frac{\mu_A(H + NI)}{kT}$$

If $\theta = \mu_A NI_0/k$ as before, and $C = I_0 \mu_A/k$, this becomes

$$I = \frac{CH}{T - \theta}$$

the Curie-Weiss law. Thus θ is explained by the existence of the molecular field NI that supports the applied field H in orienting the elementary magnets. However, as pointed out above, the fact that a paramagnetic substance follows this law does not mean necessarily that it will become ferromagnetic at temperatures below $T = \theta$.

3. Quantum Theory.—The nature of the molecular field was unknown to Weiss when he developed his theory; he knew only that its power in orienting the elementary magnets was equal to that of a magnetic field of millions of oersteds (in iron, NI is as high as 7×10^6 oersteds). An interpretation of this was first proposed in 1928 by Heisenberg who showed that it can be explained in terms of the quantum mechanical forces of exchange acting between electrons in neighbouring atoms. Imagine two atoms some distance apart, each atom with a magnetic moment of one Bohr magneton from the spin moment of one electron. A force of interaction, the exchange force, has been shown to exist between them in addition to the better-known electrostatic and (much weaker) magnetic forces. It is known that such quantum forces are negligible when the atoms are two or three times as far apart as they are in crystals. It is supposed also, on the basis

of discussions by Slater and by Bethe, that as two atoms approach each other from a distance, these forces first act to make the electron spins in the two atoms parallel (positive interaction). As the atoms come closer the spin moments are held parallel more firmly until at a certain distance the force diminishes to zero, with still closer approach, the spins are set antiparallel with relatively strong forces (negative interaction). In fig. 62 the energies corresponding to these forces are shown as a function of interatomic distance.

The interaction curve was drawn originally for atoms with definite shell radii and for varying distances from atom to atom. It may equally well be used for a series of elements if account is taken of the different radii of the shell in which the magnetic moment resides. The criterion of interaction for the metals of the iron group is the radius R of the atom (half the internuclear distance in the crystal) divided by the radius r of the 3d shell, in which the magnetic moment resides. In fig. 62 this ratio R/r has been used as abscissa and the elements chromium to nickel have been given appropriate positions on the curve. Slater showed that the ratio R/r is larger in the ferromagnetic elements than in other elements with incomplete inner shells, and that the point at which the curve crosses from the nonferromagnetic to the ferromagnetic region is near $R/r = 1.5$. This also explains how manganese becomes ferromagnetic when the atoms are separated by abnormally large distances as they are in the Heusler alloys and some compounds.

In the rare-earth elements the magnetic interaction between neighbouring atoms is best explained as interaction by way of conduction electrons. Such an electron passes near one atom and is oriented by the atomic moment; then, as it passes near a neighbouring atom the electron influences the moment of this second atom so that the moments of the two tend to become parallel.

FIG. 62.—FORM OF INTERACTION CURVE. INTERACTION MEASURED AS CURIE (OR NÉEL) POINT θ IN $^{\circ}\text{K}$.

4. Atomic Structure of Ferromagnetic Substances.—It has already been stated that the fundamental magnetic particle is the spinning electron. It might be thought that the magnetic moment from orbital motions of the electrons would also contribute to ferromagnetism; but it has been established for the iron group elements that when magnetization is altered the principal change is the direction of the spin of certain of the electrons in the atoms; the orbital motions remain practically unchanged. The basis of this conclusion is the ratio of angular momentum to magnetic moment, found experimentally by S. J. Barnett and others to be appropriate to the electron spin and definitely not to the orbital moment. On the other hand, in the rare-earth elements and compounds, the orbital moments of the electrons contribute substantially.

The electrons that are responsible for the magnetic properties of iron, cobalt, nickel and their alloys lie in a definite shell of the atom. As shown in fig. 63 there are four shells or regions into which all the electrons circulating about the nuclei of these atoms may be divided when the atom is separated from its neighbouring atoms, as it is, for example, in a gas. Two of these shells are subdivided as shown. When the atoms come closer together to form the solid metal, the fourth or outermost shell of each

FROM "RECENT ADVANCES IN PHYSICS," M. N. SHAMOS & G. M. MURPHY (ED.), BY COURTESY OF NEW YORK UNIVERSITY PRESS, 1966

FIG. 63.—ELECTRON SHELLS. SHELLS IN (A) FREE IRON ATOM, (B) Fe^{3+} ION. UNFILLED THIRD SHELL IS RESPONSIBLE FOR MAGNETIC MOMENT. ELECTRONS OF OUTER 4S SHELL OF ISOLATED ATOMS BECOME "FREE" ELECTRONS IN THE METALLIC STATE

becomes disrupted, and the two electrons which comprised it wander easily from atom to atom; these are the "free" electrons responsible for electrical conduction. The electrons in the outer part of the third shell are those responsible for the ferromagnetic moment. Some of these electrons spin in one direction and some in the opposite, as indicated, so that their magnetic moments partially neutralize each other and the excess of those spinning in one direction (+) over those spinning in the other (−) makes each atom as a whole behave as a small permanent magnet.

The average moment of the atom in a ferromagnetic material may be determined from the saturation magnetization I_0 at the absolute zero of temperature by dividing I_0 by the number of atoms in a cubic centimetre. Expressed in Bohr magnetons β this number is

$$n_B = \frac{I_0 A}{N \beta d}$$

where A is the average atomic weight, N is Avogadro's number and d is the density. Moments in Bohr magnetons, so calculated, are for iron 2.22; cobalt 1.70; and nickel 0.61.

The meaning of these non-integral values may be discussed in either of two different ways used for many problems of the solid state. In the Heisenberg approach the atoms have their own electrons (some atoms necessarily more than others), and the disturbing effect of the interaction between neighbours is estimated as well as possible. The other approach, followed by Bloch, Stoner and others, is to consider the metal as composed initially of ions and free electrons, and to calculate how the atomic fields restrict the freedom of the electrons to move. According to the latter both the 3d and 4s shells of iron, cobalt and nickel atoms are incomplete and

FIG. 64.—DISTRIBUTION OF ELECTRONS IN THE 3D AND 4S SHELLS IN IRON

there is a distribution of electrons between them that is determined by the specific nature of the atomic fields. The calculations indicate that in iron the electrons in these shells are distributed (on the average) about the nuclei as indicated in fig. 64. The 3d shell is a rather dense ring of electrons, as contrasted with the 4s shell which extends so far from the nucleus that in the solid state the shells of neighbouring atoms overlap considerably.

This description of electron distributions in their relation to ferromagnetism is supported by experiments on the alloying of nickel with copper, zinc and other elements. The substitution of one copper atom for one nickel atom in the lattice is equivalent to adding one electron to the alloy. This electron seeks the place of lowest energy in the alloy and finds it in the 3d⁺ shell of a nickel atom rather than in the copper atom to which it originally belonged. This lowers the magnetic saturation of the alloy by one Bohr unit, since the added electron in the 3d⁺ shell just neutralizes the moment of one electron in the 3d⁺ shell. Addition of more copper decreases the average moment until the empty places in the 3d⁺ shell are just full; this should occur when 60% of the atoms are copper, and then the magnetic saturation at 0° K. should be just zero. The theory is well confirmed by the data (fig. 65). When divalent zinc, that has two available electrons per atom, is added to nickel the 3d shell is filled twice as fast as with monovalent copper, again in accordance with theory; metals of higher valence behave accordingly.

5. Theory of Ferrites.—The relation of atomic moments and interaction to atomic structure and interatomic distance are well illustrated by properties of the spinel-type ferrites. Nickel ferrite, for example, has the chemical composition represented by $\text{NiO} \cdot \text{Fe}_2\text{O}_3$ or $\text{Ni}^{2+} \text{Fe}_2^{3+} \text{O}_4^{2-}$. The crystal structure is determined mainly by the oxygen ions, which are much larger than the metal ions and form a close-packed cubic array. Among the oxygen ions there are two kinds of openings in which the metal ions lie. In one kind (the A position) the metal ions are equidistant from four oxygen ions that are at the corners of a tetrahedron; in the other kind (B position) the metal ions are surrounded by six equidistant oxygen ions placed at the corners of an octahedron. In the magnetic ferrites NiFe_2O_4 half of the iron ions Fe^{3+} are in the A sites, the other half and all of the divalent ions Ni^{2+} are in the B sites.

The magnetic moments of the metal ions can be deduced from the number of electrons in the atom, as shown in fig. 63. The spin moment of Fe^{3+} is five Bohr magnetons, that of Ni^{2+} is two.

L. Néel showed that in the magnetic ferrites the interactions between the ions in the A and B sites are antiferromagnetic; thus the moments of A ions are antiparallel to those of the B ions. Since the moments are not equal the material is ferromagnetic (see fig. 7[D]). In the nonmagnetic zinc ferrites it is known that the Zn^{2+} ions are in the A sites and all of the Fe^{3+} are in the B sites. In magnetic NiFe_2O_4 and nonmagnetic ZnFe_2O_4 the situation can be represented as follows:

	Tetrahedral A sites	Octahedral B sites	Net moment (n_B)
$\text{Fe} (\text{NiFe})\text{O}_4$	Fe^{3+}	$\text{Ni}^{2+}, \text{Fe}^{3+}$	O_4^{2-}
Moments	\rightarrow	$\leftarrow \leftarrow$	
	5	2 5	2
$\text{Zn}(\text{FeFe})\text{O}_4$	Zn^{2+}	$\text{Fe}^{3+}, \text{Fe}^{3+}$	O_4^{2-}
Moments	\rightarrow	$\leftarrow \leftarrow$	
	0	5 5	0

with the moments expressed in Bohr magnetons per molecule. The net moment of NiFe_2O_4 is then expected to be two Bohr magnetons. Experimentally E. W. Gorter found 2.3. At room temperature ZnFe_2O_4 has random directions of the Fe^{3+} moments, but below 10°K . the Fe^{3+} ions go into an antiparallel arrangement and so show a weak antiparallel or negative interaction.

Similarly the moments can be estimated for the other ferrites in the series Mn, Fe, Co, Ni, Cu, Zn with increasing atomic number. The molecular moments are expected to be just those of the divalent ions of these elements, because the two Fe^{3+} ions in the A and B positions cancel each other. By using the known moments of the divalent ions and plotting the molecular moments of the corresponding ferrites the straight line of fig. 66 is produced. The observed moments, derived from the saturation magnetization at 0°K ., are shown as points. The small discrepancy between calculated moments and those observed by Gorter and C. Guillaud has been attributed to the moments resulting from the orbital motions of the electrons. The agreement between theory and observation indicates a good understanding of the atomic structure and interatomic interactions in simple ferrites.

An interesting and useful material is made by combining a small amount of nonmagnetic zinc ferrite with magnetic manganese ferrite. The magnetic moment of a mixture of 90% MnFe_2O_4 and 10% ZnFe_2O_4 can be calculated as follows:

	Tetrahedral A sites	Octahedral B sites	Net moment (n_B)
MnFe_2O_4	Mn^{2+}	$\text{Fe}^{3+}, \text{Fe}^{3+}$	O_4^{2-}
Moments	$\rightarrow 5$	$\leftarrow 5 \quad \leftarrow 5$	5
ZnFe_2O_4	Zn^{2+}	$\text{Fe}^{3+}, \text{Fe}^{3+}$	O_4^{2-}
Moments	0	5 5 (random)	0
$\{0.9 \text{ MnFe}_2\text{O}_4\}$ $\{0.1 \text{ ZnFe}_2\text{O}_4\}$	$\text{Zn}^{2+}, \text{Mn}^{2+}$	$\text{Fe}^{3+}, \text{Fe}^{3+}$	O_4^{2-}
Moments	0 \rightarrow 4.5	$\leftarrow 4.5 \quad \leftarrow 5.5$	5.5

If, therefore, some ZnFe_2O_4 is added to MnFe_2O_4 , the Zn^{2+} ions will go in the A positions and the Fe^{3+} will remain in the B positions. The net moment of the chemical mixture is found to be 5.5, an increase of 0.5 over that for MnFe_2O_4 . As long as added Zn^{2+} ions go into the A positions the moment should be expected to rise as indicated by the upper broken line of fig. 67 (ideal slope), which has this same increase of 0.5 Bohr magneton for each addition of 10% of ZnFe_2O_4 . Actually the experiments of Gorter and Guillaud give the data of fig. 67 for additions of ZnFe_2O_4 to several of the simple ferrites. The first additions give

FIG. 67.—OBSERVED CHANGE IN MOMENT OF SEVERAL FERRITES BY ADDITION OF ZINC FERRITE. IDEAL THEORETICAL INCREASE IS APPROACHED FOR SMALL ADDITIONS (E. W. GORTER, C. GUILLAUD)

curves starting with the ideal slope. Eventually the moments of ions in the A positions are too weak to influence the moments of ions in the B positions and the mixture becomes nonmagnetic like pure ZnFe_2O_4 . By the 1960s a large number of other iron-group and rare-earth-group compounds had been prepared and were found to be ferromagnetic. Of special interest are ferrites that exhibit garnet structure; e.g., gadolinium iron garnet $\text{Gd}_3\text{Fe}_5\text{O}_{12}$. Many rare-earth or other ions may be substituted for the gadolinium, and smaller ions can replace the iron; thus interactions among a variety of ions may be studied.

XIV. MEASUREMENT OF MAGNETIC QUANTITIES

1. Basic Relations.—As a prelude to a discussion of the production and measurement of magnetic fields, and the measurement of magnetization, it is desirable to consider quantitatively the fields and forces excited by currents and magnets. These may be considered as: (1) the fields produced by magnets; (2) the fields produced by currents; (3) the force on a magnet in a field; (4) the force on a current in a field; and (5) the electromotive forces produced in coils by changes in induction within them. Most of the measurements of induction and field strength are based on these relations.

Field of a Magnet.—Consider a bar magnet NS (fig. 68) of pole strength m and interpolar distance l to give a magnetic moment $M = lm$. Using the fundamental relation according to which the field strength varies inversely as the square of the distance d from a pole¹

¹This relation applies exactly when the magnet is surrounded by a vacuum when the surrounding medium is air a very small modification may be necessary. When the magnet is surrounded by a medium of permeability μ the relation is $H = m/\mu d^2$.

FIG. 66.—THEORETICAL AND MEASURED MOLECULAR MOMENTS OF FERRITES OF IRON-GROUP ELEMENTS

$$H = m/d^2 \quad (1)$$

and by adding vectorially the fields produced by both poles it may be shown that the field strength at distance r from the centre of the magnet is given by

$$H = (M/r^3) \sqrt{1 + 3 \cos^2 \theta}$$

provided that r is large compared with l . Here θ is the angle between the axis SN of the magnet and the line OP drawn from its centre to the point P at which the field is observed. The direction of the field at this point is defined by ϕ , the angle it makes with OP prolonged, and is determined by

$$2 \tan \phi = \tan \theta$$

A graphical construction based on this relation may be made by trisecting OP so that $OC = \frac{1}{2} CP$ and by drawing CD at right angles to OP to cut SN produced at D. Then DP is the direction of the field at P. Here, as elsewhere in this article, H is expressed in oersteds, B in gauss, dimensions in centimetres, forces in dynes and currents in amperes.

Important special cases are the end-on position (first Gaussian position) for $\theta = 0$, and the broadside position (second Gaussian) for $\theta = 90^\circ$. For these the fields are respectively

$$H_1 = (2M/r^3)(1 + l^2/2r^2) \\ H_2 = (M/r^3)(1 - 3l^2/8r^2)$$

When two magnets are placed very close together end to end, with opposite poles m_1 and m_2 separated by a distance d that is small compared with the extent of the surfaces, the magnets are attracted with a force that may be very strong. For each portion of one of the nearby surfaces the corresponding part of the other has an attraction given by the fundamental relation

$$F = \frac{m_1 m_2}{d^2}$$

Summing for the effect of all parts of one surface on all parts of the other gives

$$F = AH^2/8\pi$$

proportional to the pole area A , but independent of the intervening distance as long as this is small.

Fields Produced by Currents.—The simplest way of producing a magnetic field of known strength and direction is with a long coil or solenoid of wire. The field is parallel to the axis of the coil, and when a current of i amperes flows in the windings (with n turns per centimetre) the field strength within the coil is

$$H = 4\pi ni/10 \quad (2)$$

When many layers of wire are used in a solenoid that is not very long in comparison with its diameter, the field strength varies with the position, and can be calculated with the help of the appropriate formula.

When a field is produced by the current in a long straight wire of radius a , the direction of the field is everywhere at right angles to the wire axis, and at distance x from the axis the field strength is

$$H = \frac{2i}{10x}$$

outside the wire, while inside it the field strength is

$$H = \frac{2ix}{10a^2}$$

To create a relatively uniform field in a large volume H. L. F. von Helmholtz proposed the arrangement of two thin circular coaxial coils of diameter $2a$ and axial separation a . At the centre of symmetry O the field strength is

$$H = 0.899 Ni/a$$

where N is the total number of turns of wire in each coil.

Other forms of coil may be used, and the strength and direction of the field can be calculated by summing the fields produced by each current element. The magnitude of the field dH developed by a current i flowing in an element of wire dl cm. long, at a point r cm. from the current, is given by

$$dH = (i/10r^2) dl \sin \theta$$

where θ is the angle between the direction of the current and that of the line r which connects dl to the point. The direction of the field is at right angles to both the current and r .

Force on Magnet in Field.—The force on a single magnetic pole of strength m in a field of strength H is

$$F = Hm$$

dynes acting parallel to the field. In a uniform field a magnet of moment M' is acted on by a torque that tends to turn the magnet on an axis at right angles to its length and to the field so that it will lie parallel to the field. The magnitude of this torque is

$$L = M'H \sin \alpha$$

where α is the angle between the field and the long axis of the magnet. If the field is produced at P by a magnet of moment M placed at O (fig. 68), the torque acting on M' is

$$L = MM' \sqrt{1 + 3 \cos^2 \theta} (\sin \alpha)/r^3$$

If a pivoted magnet is suspended in a field it will have a natural period of oscillation equal to

$$T = 2\pi \sqrt{K/MH}$$

seconds, if K is the moment of inertia about its point of suspension. If an additional known moment of inertia k is added to that already present, without changing the magnet moment, and this increases the period to T_1 , the expression

$$MH = 4\pi^2 k / (T_1^2 - T^2)$$

can be used to determine either H or M if one of them is known.

In a nonuniform field a magnet will undergo a translational force as well as a torque, because the force pulling one pole parallel to the field will be opposed by a larger force from a larger field acting on the other pole. If the gradient of the field is dH/dx , the force on a magnet of moment M is

$$F = MdH/dx$$

This may be expressed more accurately by

$$F_x = M_x \frac{\partial H_x}{\partial x} + M_y \frac{\partial H_y}{\partial x} + M_z \frac{\partial H_z}{\partial x}$$

in terms of the x , y and z components of F , H and M . When the moment is induced by the field and is therefore

$$M = Iv = \kappa Hv$$

the force acting on the volume v is

$$F = \kappa v H dH/dx \quad (3)$$

Force on Current in Field.—When a current i flows in an element of wire of length dl in a field of strength H , the force that acts on the wire is

$$F = H i dl (\sin \theta)/10 \quad (4)$$

Here θ is the angle between dl and H , and the direction of the force is at right angles to both. When current passes through two long parallel straight wires the field of each acts on the current in the other; an attractive force is produced if the currents are in the same direction, while a repulsive force develops if they are antiparallel. Both forces, between wires a centimetres apart, are

$$F = 2ii'/(100a)$$

dynes per centimetre length of wire.

Electromotive Force Due to Changing Flux.—When an electric circuit encloses a changing magnetic flux ϕ , an electromotive

force is generated in the circuit proportional to the time rate of change of flux $d\phi/dt$, and to the number of times N the circuit threads the flux. Thus if N turns of wire are wrapped around a piece of iron of cross-sectional area A , and a change in the induction B is produced in the iron, a voltage is produced at the ends of the wire equal to $10^{-8} NA$ times the rate of change of induction in gauss per second

$$E = 10^{-8} NA dB/dt$$

The total change in B that has occurred in a specified time may be evaluated by integrating this equation with the result

$$B = 10^8 \int E dt / NA \quad (5)$$

2. Common Methods.—Ballistic Method With Ring.—In determining magnetization curves and hysteresis loops the ballistic method, employing a ring specimen, is generally the most satisfactory. H. A. Rowland used this method in 1873, and was the first to express the results of measurement in an absolute system. A ring is cut with a radial thickness that is small compared with its diameter and two windings of wire are applied (fig. 69); a secondary winding (S), usually consisting of many turns of fine wire, is wound close to the specimen and connected to a ballistic galvanometer or fluxmeter (G), and a primary winding (P) of evenly spaced turns is applied and connected to a current source. In the primary circuit means are provided for adjusting the current and for changing it rapidly from one value to another in the same or opposite direction. In the secondary circuit a mutual inductance (M) with an air core is provided for calibration and a switch is included for short-circuiting the galvanometer. The field strength H is calculated according to equation (2) from the number of turns and the dimensions of the coil and the current indicated by the ammeter (A).

When H is changed suddenly from one value to another the resulting change in B induces a voltage in the coil S and yields a deflection of the galvanometer that is proportional to the change in B , according to equation (5) above (the ballistic galvanometer has a deflection proportional to $\int E dt$ provided that the voltage impulse occurs in an interval of time that is short compared with the natural period of oscillation of the galvanometer coil and mirror). Since ballistic measurements always involve differences one must start with a known value of B . The commonest procedure for accomplishing this is first to reduce the magnetization to zero, or to demagnetize the core in an alternating field

FIG. 69.—BALLISTIC METHOD WITH RING. CURRENT IN PRIMARY WINDING P IS CONTROLLED BY RESISTANCES R_1 AND R_2 AND SWITCHES S_1 AND S_2 , AND IS READ ON METER A. SECONDARY WINDING S IS CONNECTED THROUGH MUTUAL INDUCTANCE M TO BALLISTIC GALVANOMETER G. A_1 AND S_3 ARE USED FOR CALIBRATION

of high strength, gradually reducing the amplitude to zero. To determine a point such as M in fig. 70, current corresponding to H_1 is applied and reversed several times with the galvanometer short-circuited to establish a steady cyclic state; then the galvanometer is connected and the deflection for reversal of H_1 is noted. This deflection then corresponds to a change of $2B_1$, and B_1 can be easily calculated from the constant obtained by calibration. The point M on the normal magnetization curve is thus established and other points on the curve are determined similarly.

To determine a point N on a hysteresis loop the field is alternated several times between the points of the loop (e.g., MM'), then H_1 is changed suddenly to $-H_2$ and the deflection is noted; the corresponding change in B is subtracted from B_1 , already determined, to give the value of $-B_2$ at N. By varying H_2 a sufficient number of points on the whole loop can be obtained.

The ring specimen is not adapted to rapid testing, for some time is consumed in machining the ring and in winding it with wire. However, several methods are available for the rapid application of turns. Stiff wires may be held in fixed positions and arranged so that the ring will slip over many of them at once, with the wires interconnected by a plug-and-socket arrangement

FIG. 70.—HYSTERESIS LOOP ILLUSTRATING BALLISTIC METHOD OF MEASUREMENT OF B . WHEN FIELD STRENGTH IS CHANGED FROM H_1 TO $-H_1$, B CHANGES FROM B_1 TO $-B_1$, AND GALVANOMETER DEFLECTION MEASURES THIS CHANGE IN B

there may not be enough space inside the ring. In very low fields A.C. methods should be considered.

Rod Specimens; Demagnetizing Factors.—The ballistic method may be used with a straight specimen in the form of a rod that is magnetized the same way as that used for a ring. The specimen may easily be slipped into a long solenoid that has been previously prepared, and the secondary winding or search coil should be placed around a small central portion of the specimen. Under these circumstances the more difficult quantity to determine is the field strength, because the field created by the solenoid will be disturbed by the magnetic poles of the specimen. The field created by the specimen itself is called the demagnetizing field ΔH and is proportional to the intensity of magnetization. It is usually specified by the demagnetizing factor N which depends on the ratio length/diameter of the rod

$$\Delta H = NI$$

The field acting on the middle of the rod is then the resultant of the field in the solenoid H_0 and the demagnetizing field ΔH and, when I is replaced by $(B-H)/4\pi$, is

$$H = H_0 - \frac{N}{4\pi}(B-H)$$

Values of $N/4\pi$ have been determined empirically and selected values are given in Table IV.

The term effective permeability μ' is often applied to the ratio B/H_0 , and its relation to the (true) permeability μ can be derived from the above equation

$$1/\mu = 1/\mu' - N/4\pi$$

by considering $N/4\pi$ to be negligibly small compared with one. The relation between μ and μ' for rods of various dimensional ratios $m = \text{length}/\text{diameter}$ is shown graphically in fig. 71. It is apparent that rods with m as large as 1,000 must be used to determine accurately the value of the permeability when it exceeds 100,000.

Induction varies from place to place in a bar, decreasing from the middle toward the ends. It is only when the specimen is in the form of an ellipsoid that the induction is uniform throughout. In such specimens the demagnetizing factor may be calculated accurately from the lengths of the three axes of the ellipsoid, and the direction of the induction may be determined. Equations are given below for the two most useful cases: (1) the prolate ellipsoid that has a major axis which is m times the two equal minor axes, and that is magnetized parallel to its major axis; and (2) the oblate ellipsoid or ellipsoidal disk with two long axes each of

LENGTH
DIAMETER = m

FIG. 71.—CHART FOR CONVERTING APPARENT TO TRUE PERMEABILITY, μ' TO μ , OF CYLINDERS OF GIVEN RATIO m OF LENGTH TO DIAMETER. ALSO DEMAGNETIZING FACTORS $N/4\pi$

which is m times the short axis, the specimen being magnetized parallel to a long axis.

$$\text{Prolate: } \frac{N}{4\pi} = \frac{1}{m^2 - 1} \left[\frac{m}{\sqrt{m^2 - 1}} \log_e (m + \sqrt{m^2 - 1}) - 1 \right]$$

$$\text{Oblate: } \frac{N}{4\pi} = \frac{1}{2} \left[\frac{m^2}{(m^2 - 1)^{3/2}} \arcsin \frac{\sqrt{m^2 - 1}}{m} - \frac{1}{m^2 - 1} \right]$$

Values of $N/4\pi$ for various values of m are given in Table IV.

Yokes and Permeameters.—When the specimen is in the form of a straight rod, tube or tape the demagnetizing field may be partially or completely annulled by connecting the two ends, outside the magnetizing solenoid, with magnetic material of high permeability and large cross-sectional area. Such a yoke may be used for specimens of high dimensional ratio, and measurements can be made with considerable accuracy.

More often, in the testing of permanent magnets or commercial materials in the form of bars or strips, it is desirable to use a yoke with a relatively short specimen; in this case the demagnetizing field must be taken into account or annulled in some way. One satisfactory way to accomplish both of these things is to measure the field with a ballistic galvanometer connected to a coil (H-coil) of many turns placed in the magnetizing coil and at the middle of the specimen but not surrounding it (fig. 72), and at the same time to magnetize the yoke with the current that passes through the magnetizing coil. The turns through which this current passes are adjusted to overcome the reluctance of the

FIG. 72.—SIMPLE YOKE METHOD OF COMPENSATING DEMAGNETIZING EFFECT OF ENDS OF SHORT SPECIMEN

yoke and of the air gaps at each end of the specimen that are found no matter how much care is taken to obtain good joints at these points. The search coil used in determining B is wound on the middle of the specimen as usual.

A further step toward increased accuracy was taken in the construction of the Burrows and the Niwa permeameters. These are devices that use auxiliary magnetizing and search coils to effect uniform magnetization of the specimen by compensating for the air gaps. The induction is determined with a ballistic galvanometer.

Other methods of testing with a yoke (proposed by F. P. Fahy and by A. Koepsel) have been used extensively for routinely testing standardized materials of moderate or low permeability. In the Fahy permeameter, B and H are determined with the help of coils extending the full length of the specimen and connected to a galvanometer. An auxiliary magnetizing coil is used on the yoke. The Koepsel permeameter has the advantage of direct reading since it requires no galvanometer. To indicate the induction in the specimen a coil of wire is placed on a delicate bearing in an air gap in the yoke, and when a constant current is passed through this coil it deflects in accordance with equation (4) by an amount proportional to the field strength in the gap, which in turn depends on the flux in the specimen.

In determining the magnetic properties of materials in strong fields, of the order of 300 to 10,000 oersteds or more, it is usually desirable to use some kind of an electromagnet to create the field. One good method for determining B and H is shown in fig. 73. The specimen S is placed in the air gap of an electromagnet EM and surrounded by a small coil B , preferably a short single layer of fine wire. This is connected to a sensitive fluxmeter G_B , the deflection of which is a measure of the flux change when the

FIG. 73.—MEASUREMENT OF SPECIMEN S AT HIGH VALUES OF H . INDUCTION IS MEASURED WITH COIL B CONNECTED TO FLUXMETER G_B . H IS MEASURED WITH CHATTOCK COIL C . H IS CHANGED BY VARYING CURRENT THROUGH ELECTROMAGNET EM

field of the electromagnet is changed.

The field strength acting on the specimen is measured by a Chattock potentiometer; this is made of many turns of fine wire C wound evenly on a flexible nonmagnetic semicircular form that is placed against the specimen near the ends of the coil B. The deflection of the fluxmeter G_H measures the change of field strength as the coil C is brought from zero field into its place against the specimen.

A high- H permeameter was also designed by R. L. Sanford and E. G. Bennett for measuring B in strong fields.

Alternating Current Methods.—A.C. testing methods are principally used for determining (1) permeability and energy losses of thin sheet at low inductions, usually not more than a few hundred gauss, using an inductance bridge; and (2) energy losses at high inductions, usually $B = 15,000$, using the Epstein method.

A diagram of the inductance bridge is shown in fig. 74. Current of the desired frequency f is supplied by an oscillator and fed to opposite corners of the bridge through a transformer and a thermal ammeter A. Two equal fixed resistances R_1 constitute two arms of the bridge, and in the others are the specimen S, variable inductance L and resistance R. When the bridge is balanced by adjusting L and R until no voltage is detected through the headphones P or other instrument connected through a transformer and amplifier, then L and R are equal to the inductance and A.C. resistance of the winding that encloses the specimen. The permeability can be calculated from L, the dimensions of the specimen, the field strength from the current through the core winding, and the energy loss in the specimen from the resistance R, correction being made for the losses in the copper wire. In another common modification of the Maxwell bridge L is replaced by a variable condenser connected in parallel with the variable resistor.

To avoid the application of many turns of wire to the specimen, necessary when low inductions are measured, G. A. Kelsall has used a device indicated schematically at K in fig. 74. Instead of connecting the windings of a specimen directly to one arm of the bridge in the usual way, a transformer with a many-turn primary and a single-turn secondary is substituted. This turn is wound on the specimen also, and the bridge is balanced as before. The core of the transformer is of high-quality laminated material that has low losses which must be subtracted from the bridge measurement to calculate the loss in the specimen. This instrument has been adapted for use at high temperatures as well as at ordinary temperatures.

In interpreting the permeability and energy losses measured by A.C. methods one must consider the apparent reduction of permeability from skin effect or shielding that arises from eddy

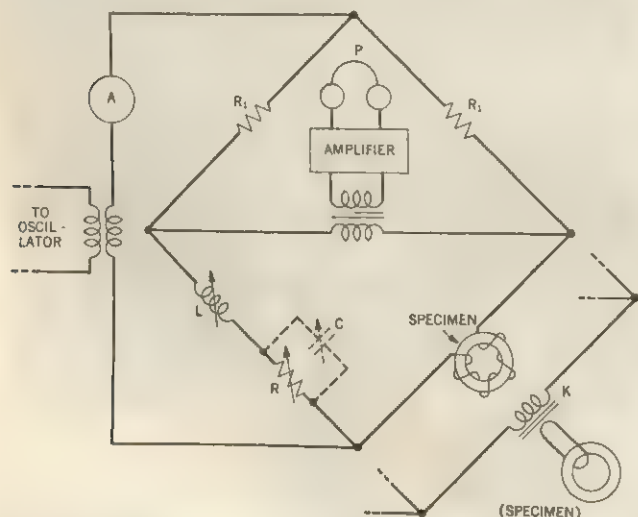

FIG. 74.—THE INDUCTANCE BRIDGE MEASURES RESISTANCE AND INDUCTANCE OF WINDING SURROUNDING SPECIMEN. ALTERNATIVELY, L MAY BE OMITTED AND A VARIABLE CONDENSER C MAY BE INSERTED IN PARALLEL WITH R. SPECIMEN MAY BE CONNECTED THROUGH TRANSFORMER X THAT HAS SINGLE-TURN SECONDARY LOOPEL WITH SPECIMEN

FIG. 75.—EPSTEIN OR LLOYD-FISHER APPARATUS. THIS APPARATUS MEASURES POWER DISSIPATED IN A SPECIMEN FORMED FROM STRIPS. COIL FORM-WOUND AS SHOWN IN (A) ARE CONNECTED AS SHOWN IN (B) TO VOLTMETER V AND WATTMETER W

currents, and the separable losses attributable to eddy currents and hysteresis. These data obtained with the A.C. bridge are especially important in the study of materials used in communication engineering where small magnetic fields are important in the transmission of weak or undistorted signals.

The Epstein or Lloyd-Fisher apparatus is used primarily for measuring magnetic losses in material for transformers operating at high inductions. The material in the form of strips is built into a hollow square. An alternating field is applied in one winding to magnetize it to a high induction measured by the voltage induced in a second winding; the loss is indicated by a wattmeter W connected to the circuits of both windings (fig. 75). Both windings are placed evenly on forms with square sections, and four such forms are placed to make a hollow square. The strips are slipped into the forms and carefully clamped at the corners after being abutted or overlapped there. Standard specifications control the manner of cutting and stacking the specimens, of correcting for the air flux in the coils and of taking into account the wave form of the exciting current. Measurements are commonly made at $B = 15,000$ and at a frequency of 60 cycles/sec. in the U.S. and 50 cycles/sec. in England.

In principle a simple method of testing by A.C. is to determine the current-voltage characteristics of a specimen that has two windings, the current being a measure of H and the voltage a measure of B . The several methods for accomplishing this involve potentiometric measurements or rectification. From the results one can determine not only B and H , but also by taking account of the phase the total energy loss in the material can be found.

3. Special Methods.—Measurements of very small quantities of materials, of single crystals in definite directions, of paramagnetic or diamagnetic solids, liquids or gases all require special arrangements for obtaining results of high accuracy with a minimum of effort.

Years ago the intensity of magnetization of a specimen was usually measured by the torque it exerted on a small magnetic needle of known moment suspended nearby. The deflection of a light beam by a mirror attached to the delicate suspended system is still a very sensitive indicator of magnetization, but for most purposes the uncertainty in the positions of the magnetic poles of the specimen gives the magnetometer low precision.

In principle the magnetometer measures field strength at a known distance from the poles of the specimen, in accordance with equation (1). It has been used for measuring, with not too great accuracy, the magnetic properties of very small specimens in the form of fine wires or thin films deposited by evaporation or electro-deposition.

Measurements of weakly magnetic substances usually depend on the translational force on a magnetized body in a nonuniform magnetic field. Faraday suspended the sample between the poles of an electromagnet, displaced from the central position so that the field gradient was large, and used a torsion balance to measure the force moving the material toward or from the stronger part of the field. This method was developed by Curie and used in his classical researches on the effect of temperature on paramagnetic and diamagnetic materials.

When the field gradient is dH/dx , the force on material of magnetic moment M is MdH/dx dynes; when expressed in terms of susceptibility and volume the force is given by equation (3). The force is zero at the central position between the poles of the magnet because here dH/dx is zero, and the force is a maximum at some point and falls off again toward zero at points distant from the magnet.

To avoid laborious mapping of the field to find HdH/dx , and to dispense with careful setting of the sample at a given position, C. Chéveneau proposed that the magnet be moved until the sample shows maximum deviation from its zero position against the restoring force of a torsion balance. The deflection is then proportional to the susceptibility and to the maximum value of HdH/dx , and the proportionality factor is determined by calibration with a substance of known susceptibility.

An ingenious quick-reading device designed by W. Sucksmith is shown schematically in fig. 76. The specimen M is suspended from a ring R made of a flexible strip of metal that deforms when the specimen is pulled into the inhomogeneous field of the electromagnet EM . The deformation of the ring is measured with a beam of light L reflected from two mirrors AB to a scale S . The deforming force is proportional to the intensity of magnetization of the specimen; the constant of calibration is obtained using a magnetic material of known magnetization. The method is applicable to ferromagnetic and paramagnetic substances.

Magnetization in strong fields may also be measured by the method of extraction, used first by Weiss and Forrer. The specimen is placed in the field of an electromagnet and then suddenly removed. During removal it induces a voltage in a coil fixed to the magnet, and the integrated voltage (proportional to the magnetization of the specimen) is measured by ballistic galvanometer.

Special methods have been adapted for use in cryostats for measurements at low temperatures (e.g., 1°K). Among these is the method of S. Foner (1959), in which a probing coil is placed near the vibrating specimen, and the voltage induced in the coil (proportional to the magnetization) is amplified electronically and recorded. In another method, used by Bozorth and Williams (1956), the sample is in an inhomogeneous field at the end of a vertical pendulum, and the horizontal deflection of the pendulum is measured with strain gauges.

The force exerted upon a magnetic material in an inhomogeneous magnetic field is also the basis of the methods of L. Gouy and G. Quincke for measuring the susceptibilities of liquids. There are numerous modifications of the original methods and adaptation has been made to the measurement of gases. The force on the liquid in the field is measured by its rise in a capillary tube, against the force of gravity. The force on a column of liquid (or gas) extending from a place where the field is H_1 to where it is H_0 may be obtained by integration of equation (3) to give

$$F = \kappa A(H_1^2 - H_0^2)/2$$

where A is the cross-sectional area of the column. If a column of liquid (susceptibility κ_1) is opposed by a column of gas (susceptibility κ_2) the relation becomes

$$F = (\kappa_1 - \kappa_2)A(H_1^2 - H_0^2)/2$$

Usually H_1 is the field strength directly between the poles of the magnet at the boundary between liquid and gas, and H_0 at the other end of the column is negligibly small. The susceptibility of gases has also been measured with a sensitive torsion balance.

Measurements of the saturation magnetization of ferromagnetic materials were made with great accuracy by Weiss and his students in fields up to 20,000 oersteds, at temperatures ranging from about -250° to $+800^\circ \text{C}$. They used some modification of the scheme shown in fig. 77 in which the force is produced by a field gradient as in the Faraday method, but is measured as a translation instead of a torsion. Such a pendulum magnetometer has a light horizontal beam with the specimen mounted at one end in a region of strong field gradient. The force due to the field is annulled by adjusting a current in a solenoid in which a plunger is attached to the other end of the beam, and the point of zero deflection is indicated by a tilting mirror.

Other methods of measurement in strong fields deserve brief mention. H. DuBois measured the intensity of magnetization by

FIG. 77.—PENDULUM MAGNETOMETER. SPECIMEN IS HUNG FROM THREADS ON LIGHT FRAME. INHOMOGENEOUS FIELD OF ELECTROMAGNET (HALF OF WHICH IS SHOWN) PRODUCES HORIZONTAL MOTION OF FRAME, DETECTED BY TILTING OF MIRROR. MOTION IS COMPENSATED BY MAGNETIC PLUNGER IN SOLENOID, CURRENT THROUGH WHICH IS MEASURE OF MAGNETIZATION OF SPECIMEN (P. WEISS AND F. FOEX)

observing the rotation of polarized light reflecting from a magnetized surface (Kerr effect). The strength of a field can be measured by observing the force (opposing gravity) produced on a conductor carrying a known current (equation [4]) or by using a calibrated Hall-effect probe (see ELECTRICITY, CONDUCTION OF: *Conduction in Solids: Semiconductors*). Special methods have been devised for measuring magnetic properties that vary with direction, as in single crystals.

In the 1960s steady magnetic fields of more than 100,000 oersteds and pulsed fields that exceed 1,000,000 oersteds were produced in solenoids, sometimes with superconducting wire maintained at low temperature (see SUPERCONDUCTIVITY).

In weak fields, such as that of the earth, the methods of geomagnetism (*q.v.*) can be used. In 1936 an apparatus was constructed for measuring and recording rapid changes in fields as small as one gamma (10^{-5} oersted), and during and after World War II this method was developed to even higher sensitivity (10^{-7} oersted). A piece of high-permeability material is subjected to an alternating field of moderate amplitude, and if an additional steady field (that to be measured) is also present an alternating voltage of twice the exciting frequency will be produced that can be amplified and recorded. Its amplitude is proportional to the field strength to be determined.

The strength of high fields is now measured with high accuracy with the use of nuclear resonance. In principle this is the same as ferromagnetic resonance except that the magnetic moment of

FIG. 76.—SUCKSMITH BALANCE (see TEXT)

the nucleus is much smaller than that of the electron; thus the frequency of resonance is correspondingly lower, and lies in the radio-frequency range for the nuclei of hydrogen and lithium atoms, which are most commonly used for measurement. The measurement of the field strength is then reduced to the measurement of a radio frequency, and can readily be done with a precision of a few parts in 1,000,000. A material that contains hydrogen or other nuclei with constants that are known with high accuracy is placed in the field to be measured, the weak radio-frequency field is applied at right angles to the principal field and the frequency is varied until resonance occurs.

A number of curve tracers have been made for taking magnetization curves and hysteresis loops so that a permanent accurate record may be obtained in a short time. Among the more accurate and convenient of these is P. P. Cioffi's device. For the investigation of magnetic properties at high frequencies special techniques of some complexity must be used.

MAGNETITE or **MAGNETIC IRON ORE**, a member of the spinel group of minerals with the formula Fe_3O_4 (or FeFe_2O_4), is an important ore of iron found in commercial quantities in northern Sweden, Norway and Rumania and in the Ural mountains; in the United States—New York, New Jersey, Pennsylvania and Utah (and in some of the ores of the Lake Superior district). It is a black, opaque mineral with metallic lustre. Hardness, about 6. Specific gravity, 4.9 to 5.2. Streak, black. Magnetite, also known as the lodestone, is strongly magnetic and frequently polar and has been known from very early times for this remarkable property which was described by Pliny (see also **MAGNETISM: History**). It crystallizes in the cubic system, in which it occurs usually in octahedra, and is frequently twinned. There is no distinct cleavage.

Magnetite is a mineral of wide distribution, especially as a constituent of igneous rocks, both intrusive and volcanic. It appears to have crystallized from the magma at an early period of consolidation, and marginal segregation has led in many cases to the formation of ore deposits. Being a mineral not prone to decomposition, it is also found in detrital deposits, sometimes in a concentrated form, as magnetite sand. The existence of pseudomorphs of magnetite after hematite (*q.v.*) and vice versa, however, prove that these minerals may be converted into one another by a change in the state of oxidation. Oxidation and hydration in the zone of weathering lead to limonite (*q.v.*). Titaniferous magnetite or titanomagnetite is a variety containing titanium. It consists of an intergrowth in various proportions of the minerals magnetite and ilmenite (*q.v.*).

MAGNETO, HIGH-TENSION. The magneto is a special application of the electric generator employed where the output of energy required is very small. It is used to furnish energy for ignition of compressed gases in various types of internal-combustion engines. The elements of construction comprise a permanent magnetic field, an armature rotated within that field, a circuit breaker and a distributing mechanism which serves to convey the generated voltage to a desired point. The low-tension magneto consists merely of a permanent

BY COURTESY OF J. H. CROWNE

FIG. 2.—SIMPLE ELECTRIC WAVE FORMED IN A MAGNETO, SHOWING POSITION OF THE ARMATURE AND THE CURRENT PHASE FOR EACH POSITION

magnet of inverted U form and, rotating between its poles, a shuttle-wound armature containing a number of turns of comparatively coarse wire, as shown in fig. 1.

The changes of flux in the armature core, caused by its rotation in the permanent field, generate in the armature winding an electromotive force, the magnitude of which is proportional to the field strength, the speed of rotation and the number of turns of wire on the armature. As the armature core rotates into a position in a plane with the flux lines, the flux in the core increases to a maximum. As the rotation progresses, the flux in the core decreases for one-half cycle. In the second half cycle, the coil direction is reversed with relation to the flux.

The generated electromotive force, consequently, is alternating in direction and magnitude and follows the variation of flux in the core. The change of electromotive force with change of position of the armature is shown in fig. 2. The low-tension magneto has been used in conjunction with an induction coil as an ignition source, the coil serving to transform the voltage to a value sufficient to cause a spark across the terminals of a spark plug.

High-Tension Magneto Construction.—The high-tension magneto has a secondary winding, comprising a great many turns of fine wire superimposed upon the primary winding. The primary winding is short-circuited by means of an auxiliary device during the building up of the field in the armature core. When the energy in the primary circuit has reached a maximum, this circuit is opened, and at the same instant, as a result of the rotation of the armature, the magnetic field is removed. The energy of the primary winding is discharged through the secondary, and as a result of the ratio of primary to secondary turns, a considerable increase in voltage is effected. This value may vary between 7,500 and 18,000 v. The high-tension magneto when employed as a source of ignition for gas engines is operated synchronously with the engine by direct connection.

Fig. 3 shows the construction of a shuttle-armature type of high-tension magneto. The circuit breaker is operated by means of a cam, upon which the bumper, or cam follower on the breaker bar, bears. Since the armature is directly connected to the engine, the frequency of the discharges through the secondary circuit is thus determined. (A shuttle armature, having two poles, can generate two spark discharges per revolution.) The distributor serves to

BY COURTESY OF J. H. CROWNE

FIG. 3.—UNIT COIL FOR GASOLINE MOTOR IGNITION SYSTEM

FIG. 4.—CROSS SECTION OF INDUCTOR MAGNETO

convey the voltage to each of the spark-plug cables, in a desired sequence. Operating in synchronism with the armature, from which it is driven by means of a gear and pinion, the brush or firing pin of the distributor arm makes contact with a segment in the distributor block each time the secondary discharge occurs. By this means, the high-tension energy is carried to each spark plug in order. For a four-cylinder engine, the distributor block carries four segments, and since the shuttle armature generates two sparks per revolution, the gear ratio between armature and distributor is 2:1. The primary and secondary windings are common at one point and are there connected to the frame of the magneto. The return circuit of the secondary is thus completed through the body of the engine. The contact points of the circuit breaker, or interrupter, are made of an arc-resistant alloy.

An improvement in magneto design was offered in the inductor-type instrument in which the coil is stationary and the flux changes are brought about by means of magnetic shunt segments which rotate between the magnet poles and bridge between them and the coil core. A cross-sectional drawing of this type is shown in fig. 4. By the use of four rotor segments, spaced 90° apart, four sparks per revolution may be generated. In addition, the flux direction through the coil core is reversed each quarter revolution. The direction of current through the contact points of the interrupter is thus alternated, and the excessive point pitting caused by a unidirectional arc is eliminated.

In order to vary the time of occurrence of the spark in the engine cylinder, the magneto cam, or the circuit breaker, is made rotatable through part of a revolution, and is connected, by means of a linkage, to a convenient advance-retard lever. This makes it possible to alter the relationship between the engine crankshaft and the magneto, and to ignite the charge either before or after the piston has reached its dead centre position. Since the spark intensity of a magneto varies directly with engine speed, there is available an increase of energy at high speed when the requirements for ignition are most severe. At low speeds of rotation such as accompany the cranking or starting of automotive engines, the magneto will sometimes fail to produce a voltage sufficient to spark across the gap. There have been in use various impulse devices, such as "impulse couplings," which serve to couple the magneto to the engine and to accelerate its rotation in starting.

The magneto is employed on aircraft engines, where the highest engine efficiency must be maintained; on tractor engines, motor-cycles, marine engines and to a great extent on motorbuses and motor trucks. Stationary engines are also magneto equipped. Minor commercial uses are found in the igniting of blasting charges (detonators), in igniters, for oil or gas burners; and, in conjunction with neon lamps, as stroboscopic indicating instruments.

MAGNETOCHEMISTRY. Because it is strongly attracted by a magnet, iron is said to be ferromagnetic. There are relatively few ferromagnetic materials, but other substances show either a weak attraction or a very weak repulsion by a magnet. Substances thus weakly attracted are said to be paramagnetic, those repelled are diamagnetic. Magnetochemistry is the branch of chemistry in which these and other magnetic properties are used to solve chemical problems.

There are at least four major applications of magnetism to chemistry. These are (1) qualitative and quantitative chemical analysis; (2) the study of free radicals; (3) the structure of inorganic compounds; and (4) the mechanism of catalysis. Since about 1950 the range of such studies has been greatly extended owing to the development of two new experimental methods, nuclear magnetic resonance and electron magnetic resonance.

Magnetic apparatus may be used for the detection of paramagnetic impurities in diamagnetic substances, and especially for ferromagnetic impurities. The sand used for making glass must often be as free as possible from iron. Use of the magnetic balance will often detect a very small trace of iron in such sand. Similarly, traces of iron or of other ferromagnetic substances may be detected in metals such as magnesium. The term "magnetically pure" is sometimes used for substances which have been shown, by magnetic tests, to be free from impurities. Another analytical application is that of measuring the concentration of oxygen (which is almost unique among gases in being paramagnetic) in a mixture of gases. The magnetic method is a useful tool for a variety of chemical and metallurgical tests, including precipitation studies, and granulometry or the measurement of the radius and shape of extremely small particles. This subject is often called "thermomagnetic analysis."

Another use of magnetism in chemistry is in the study of free radicals. These substances, of which triphenylmethyl is one, possess an odd number of electrons (except for a few special cases) and are paramagnetic. Most chemical substances possess an even number of electrons and are diamagnetic. Electron magnetic resonance is especially useful in this field. An active area for magnetochemical study is the atomic and molecular relationships in inorganic compounds. Hemoglobin, the red matter in blood, is a good example. Hemoglobin serves as the carrier of oxygen. It is composed in part of a complex compound containing iron. This substance is paramagnetic but when the hemoglobin takes up oxygen, as it does in passing through the lung tissues, the hemoglobin becomes diamagnetic. Studies of a related nature are made on substances called ferrites, of which nickel ferrite is one. Ferrites are used in electronic equipment.

A field of usefulness and promise is the application of magnetic methods to catalysis. Certain elements such as chromium and nickel and their compounds, which show catalytic activity, show also interesting magnetic effects. In some cases it is reasonably well established that catalytic activity and paramagnetism (or ferromagnetism) have a common underlying basis in the presence of unpaired electrons in certain atoms. This correlation has proved fruitful in the study of chemisorption (see ADSORPTION), that is, the way in which molecules adhere to the surface of the catalyst prior to and during catalyzed chemical reaction.

See P. W. Selwood, *Magnetochemistry* (1956). (P. W. S.)

MAGNETOHYDRODYNAMICS, or hydromagnetics, in its most general sense is the study of the motions of electrically conducting fluids (liquids and gases) in the presence of electric and magnetic fields. Occasionally the term has been restricted to liquids, with magnetogasdynamics and plasma physics used in the case of gases. In physics, plasma is a gas of electrically charged particles (see ELECTRICITY, CONDUCTION OF).

Principles of magnetohydrodynamics have assumed importance in efforts to design reactors for generating power from thermonuclear sources; it is hoped that appropriately designed magnetic fields will serve to confine the plasma of hydrogen isotopes in which fusion occurs. The behaviour of particle accelerators, electrical propulsion devices for space vehicles, the aurora and Van Allen radiation belts, as well as related phenomena or equipment also may be described in magnetohydrodynamic terms. See

ATOMIC ENERGY: *Peacetime Applications*; ACCELERATORS, PARTICLE; AURORA POLARIS; VAN ALLEN RADIATION BELTS.

Early magnetohydrodynamic studies (for example, those of Michael Faraday in 1832) dealt with liquid metals. Liquid mercury was used by Y. Nakagawa (1957) to determine the effect of a magnetic field in inhibiting thermal convection; at higher temperatures, molten sodium has been used. It is believed that the earth's core, below about the 1,800-mi. depth, is composed largely of molten iron and nickel. The connection of earth's magnetic field with this conducting, liquid core has been a magnetohydrodynamic problem of interest in geophysics (see GEOMAGNETISM). However, most of the magnetohydrodynamic problems of interest in the 1960s involve gases. At ordinary temperatures and pressures gases are groups of electrically neutral atoms or molecules and therefore do not conduct electricity. However, at temperatures of several thousand degrees centigrade and above (depending somewhat on the gas pressure), the thermal motions of the particles are energetic enough to dislodge some of the outer electrons from the atoms. The electrons thus freed, and the resulting positive ions, are easily made to move by an electric field, so that such ionized gases (plasmas) are usually good conductors of electricity. Natural plasmas occur in the sun and other stars, in the upper parts of earth's atmosphere, and in the extremely low-density gas clouds in interplanetary and interstellar space. Plasmas also have been studied extensively in the laboratory, the chief interest being in their possible use as sources of power (see ENERGY CONVERSION, DIRECT).

Basic Principles of Magnetohydrodynamics.—All fluids are groups of particles in varying states of aggregation, and the motion of a fluid is therefore given by the motions of its particles. If each particle is labeled with an index $i = 1, 2, 3, \dots, N$, where N is the total number of particles (very large usually), then Isaac Newton's equation governing the motion of the i th particle is

$$a_i = \frac{f_i}{m_i} \quad (1)$$

Here a_i is the acceleration of the i th particle, and the equation states that the acceleration is proportional to the force f_i acting on the particle and inversely proportional to its mass m_i . The forces acting on the particles are generally: (1) gravitational forces; (2) forces exchanged during collisions among particles; and (3) forces from electric and magnetic fields.

The weak gravitational forces sometimes can be important in stellar and geophysical problems, but usually may be ignored in magnetohydrodynamic studies on a laboratory scale. The collisional forces are atomic in origin, and the exchange of momentum in collisions is connected with the phenomenon of pressure. A gas exerts pressure on its container through multitudinous impacts of its atoms with the wall. In the same way, neighbouring volume elements in a gas or liquid exert pressure forces on each other.

A charged particle in an electric field E and a magnetic field B is subject to the Lorentz force

$$f = q(E + v \times B) \quad (2)$$

Here q is the electric charge of the particle and v is particle velocity. While the electric field exerts a force in the direction of the electric field, the magnetic field exerts a force at right angles to both the magnetic field and the particle velocity, as is implied by the cross (\times) product (see VECTOR ANALYSIS: *Products of Vectors*).

Equations (1) and (2) together determine the motions of the particles, given the electric and magnetic fields. The fields, however, are determined in turn by the motions of the particles. If at some time, for example, there happen to be more positive than negative particles in a small volume element, the element has a net positive charge that gives rise to an electric field. Also, moving-charged particles constitute an electric current, and currents give rise to magnetic fields. Mathematically, the relation of the fields to the charges and currents that produce them is expressed by James Clerk Maxwell's equations (see ELECTROMAGNETIC WAVES: *Maxwell's Field Theory*). These, together with equations (1) and (2), are sufficient to determine the behaviour of the entire

system of particles and fields if the initial conditions are specified.

In practice it is rarely (if ever) possible to solve the equations of motion for all of the particles, simply because there are so many of them. To make any headway, it is necessary to forego precise reckoning, and be content with knowing average properties of the fluid. Thus, instead of hoping to specify the positions of all the particles, the investigator settles for knowing the mass density μ , that is, the total mass of the particles in small but finite volume elements (cells) divided by the volume of the cells. The cells must be sufficiently large to contain enough particles to make statistical fluctuations unimportant, but small enough to keep density from changing too much from cell to cell. It is usually possible to select a cell size that satisfies both criteria.

Next, instead of the velocities of all the particles, the average velocity u of the particles in each cell is accepted. A cork floating in a creek shows the average velocity of the water molecules in its neighbourhood. It must not be assumed that all the molecules around the cork travel at this velocity. At ordinary temperatures water molecules dash randomly about with velocities the order of 1,000 ft./sec., aside from whatever average velocity they may have. The mean random velocity (average deviation from the average velocity) must also be used in the simplified description of the fluid. It is the essence of the property called temperature: the higher the random velocity, the higher the temperature. It is important in determining fluid motions, because the pressure depends on it: collisional forces are larger when random velocity is higher.

The density μ , the average or fluid velocity u and the temperature T are sufficient parameters to describe a situation in ordinary hydrodynamics. Magnetohydrodynamics also requires the electric and magnetic fields, the electric charge density ρ and electric current density j . The charge density is the net excess of positive over negative charge per unit volume, and the current density is net charge times velocity per unit volume; clearly these are *a.s.o.* averages.

Equation (1), when averaged over all particles moving in a cell, becomes

$$\dot{u} = \frac{1}{\mu} [\nabla p + \rho E + j \times B] \quad (3)$$

Here \dot{u} is the acceleration (time rate of change of the average velocity u in some cell). The pressure (which depends on T and μ) is represented by p , and ∇p is the difference of the pressure forces acting on opposite faces of the cell. The other two terms in the bracket are the electric and magnetic forces acting on the cell. In writing equation (3) the gravitational forces have been assumed to be negligible; they could be included in the bracket. Equation (3) is the equation of motion of the most rudimentary form of magnetohydrodynamics.

All the forces in equation (3) are of fairly common experience. The pressure is the force felt in trying to stop the flow of water from a faucet by holding a finger over the opening. The electric force can be observed by rubbing a plastic hairbrush handle with wool cloth and then holding the handle near a very thin stream of water; the electric force will deflect the stream toward the plastic. The magnetic force on currents is the driving force in electric motors.

In many applications of equation (3) the electric force is negligible, because concern is often with fluids that are very good conductors of electricity. In such cases even small electric fields generate very large electric currents, which rapidly neutralize the excess charge that produced the electric fields. Thus, charge densities and electric fields are small, but the currents and magnetic fields they produce are large.

As a further simplification, it can be shown in this case of high electrical conductivity that the magnetic field lines can be regarded as moving with the fluid. This is of great help in providing an intuitive feeling for the changes in the magnetic field patterns that accompany various motions of the fluid.

An intuitive grasp of the magnetic forces is provided by Michael Faraday's concepts of magnetic field lines. Faraday observed that the field lines can be regarded as transmitting a tension along

the lines and a pressure in directions perpendicular to the lines, the magnitude of both tension and pressure being equal to $B^2/8\pi$. These ideas help in understanding the attraction of two opposite magnetic poles and the repulsion of like poles. In fig. 1(A) the field lines are all perpendicular to the central plane; thus a tension is transmitted across this plane as if a stretched spring connected the north and south poles. In fig. 1(B) the field lines run parallel to the central plane, so that a pressure is transmitted across the plane as if a compressed spring connected the two north poles. Magnetic forces can be understood either as forces on currents or as tensions and pressures in the field; the two descriptions are completely equivalent.

FIG. 1.—ATTRACTION AND REPULSION IN TERMS OF MAGNETIC STRESSES

Hydromagnetic Waves.—To understand some simple hydromagnetic phenomena consider first two types of hydromagnetic wave: transverse and longitudinal.

Transverse Waves.—Suppose there is a homogeneous fluid of density μ with a uniform magnetic field B as in fig. 2(A). Then let alternate vertical layers of the fluid be displaced upward and downward, transverse to the original field. If the fluid is a good conductor, the field lines will be displaced with the fluid as in fig. 2(B). Since the field lines are in tension, they tend to shorten

FIG. 2.—TRANSVERSE HYDROMAGNETIC WAVE

by straightening to their original position, carrying the fluid with them. However, when the field lines reach the straight configuration, the fluid layers have some velocity and fluid inertia will carry the field lines farther until the crests and troughs of fig. 2(B) are precisely interchanged. The action then reverses and continues, to produce a standing wave. Calculation shows that the frequency f and the wavelength λ of these waves are related by the expression

$$f\lambda = \frac{B}{\sqrt{4\pi\mu}} \quad (4)$$

The quantity on the right is the propagation velocity of the waves (called the Alfvén velocity after the Swedish astrophysicist who first discussed hydromagnetic waves).

Longitudinal Waves.—Again start with uniform fluid and magnetic field as in fig. 3(A). Now let alternate vertical layers of the fluid be displaced to the right and left so that the fluid becomes denser in some regions and less dense in others (fig. 3[B]).

FIG. 3.—LONGITUDINAL HYDROMAGNETIC WAVE

Again, if the fluid is a good conductor, the field lines will be compressed and rarefied with the fluid. In the compressed regions the magnetic pressure will be larger than in the rarefied regions, tending to force the fluid back to the uniform configuration. Again, the inertia of the fluid will carry the field beyond the uniform configuration to produce oscillations. If the fluid pressure is negligible compared to the magnetic pressure $B^2/8\pi$, the frequency f and

wavelength λ of these waves are also related by equation (4). When the fluid pressure is much higher than the magnetic pressure these longitudinal waves become ordinary sound waves.

In general, for every problem in ordinary hydrodynamics there is a corresponding problem in magnetohydrodynamics. Usually the addition of the magnetic field complicates the problem because of the peculiar tendency of the field to have tensions in some directions and pressures in others.

Hydromagnetic Dynamo Theory of Earth's Magnetic Field.—The mechanism responsible for earth's magnetic field has been a long-standing scientific puzzle. Some source of energy is needed to maintain the field. A system of electric currents could produce the field, but since the earth has electrical resistivity these currents would slowly die away and the magnetic energy would be spent as heat. From the known resistivity of iron, the field should decrease by an estimated factor of 10 every 1,000,000 years. The earth is believed to be several billion years old; thus either its field was inordinately large in the beginning or some source replenishes the energy dissipated in the resistance.

Probably the most commonly accepted idea at present is that the energy comes from motions of molten iron in the earth's core across the magnetic field. The fluid motions may be convective, driven by rising temperature with depth and influenced by the rotation of the earth. In moving across the magnetic field, the fluid is held to generate an electromotive force (as does the armature of a dynamo) that maintains the current. The energy to maintain the currents then would come from the fluid motions, in turn supplied from the earth's heat energy (and possibly from the earth's rotational energy). The earth's heat is a much larger store of energy than the magnetic field; the field contains on the order of 0.1 erg/c.c., while the heat represents on the order of 10^{10} erg/c.c.

The specific form of the fluid motions held to maintain the field is not known. As one example of fluid motions that increase magnetic energy, start with a uniform magnetic field (fig. 4[A]). Imagine the fluid above the plane xy is displaced to the left with respect to the fluid below the plane. If the field lines are carried along, the field is distorted as in fig. 4(B). The field lines are

FIG. 4.—INCREASE OF MAGNETIC ENERGY BY A SHEAR FLOW

then closer together in the region of shear. This means that the magnetic field and the magnetic energy are greater there than elsewhere; the fluid has done work in stretching the field lines.

In this example the additional field tends to be at right angles to the original field. The question of how or whether the new field becomes aligned to reinforce the original field is not fully answered.

Many stars, including the sun, have magnetic fields attributed to the same type of mechanism. In many stars the field is strong (several thousand gauss) and reverses polarity at intervals as short as a few days; sunspots reverse polarity with a half-period of 11½ years. There is also good geologic evidence that earth's field has reversed many times in prehistory; the reasons are not understood.

Magnetohydrodynamics in the Solar System.—In addition to the magnetic fields in and near the earth and sun, variable magnetic fields permeate interplanetary space. It is likely that these fields are carried from the sun by jets of hot solar plasma. The surface of the sun often shows violent eruptions of visible hot gases accompanied by magnetic fields. Presumably these eruptions result from turbulence of the convective region that normally lies just below the visible solar surface. It is believed that in at least some of these eruptions, invisible jets of low-density gas are shot out as far as the earth and farther. This solar wind of ionized

gas distorts and shakes earth's magnetic field in much the same way that a windstorm affects a tree; instruments on earth then record a magnetic storm (*q.v.*). The magnetic storm usually begins about a day after an eruption is seen on the sun, indicating that the velocity of the gas is about 10^8 cm./sec.

Two successive stages of the gas motion and the magnetic field carried with it from the sun are illustrated in fig. 5. Evidence for the gas-borne magnetic field is found in the decrease in cosmic-ray intensity just prior to a magnetic storm. Called the Forbush decrease, it arises when continuously falling cosmic rays are deflected from earth as a result of the magnetic field accompanying

FIG. 5.—MAGNETIC FIELD PULLED OUT BY IONIZED SOLAR GAS JET

the gas. Experiments in the U.S. satellite Pioneer V showed that the Forbush decrease results not only from modification of earth's field but occurs over much larger volumes of space (see *Cosmic Rays: Nature and Origin of Primary Rays*).

High-energy protons that often accompany the gas cloud are further evidence for the magnetic field. It is believed that these protons come from solar flares (which can be timed by the bursts of radio noise they generate). The energy of the protons corresponds to velocities on the order of 10^{10} cm./sec. Thus, if unimpeded, they should reach earth in $\frac{1}{100}$ the time required for the gas jet. Yet experiments suggest that many of the protons arrive only when the gas reaches earth. In explanation, it is supposed that these high-energy protons are trapped in the magnetic field carried by the gas.

The trapping of charged particles by magnetic fields is basic in magnetohydrodynamics. As noted in equation (2), the magnetic force on a charged particle is perpendicular to the particle velocity and to the magnetic field. As a result, the motion of a charged particle (in a plane perpendicular to the magnetic field) is circular, the magnetic force always being directed toward the centre of the circle. Since it also moves parallel to the field, the particle has a helical trajectory in a uniform magnetic field (fig. 6[A]). The particle can move in either direction along the field, keeping the same field line as the centre, and always encircling the same amount of magnetic flux. This holds approximately for nonuniform fields: fig. 6(B) (curved field lines) and fig. 6(C) (diverging field lines).

FIG. 6.—CHARGED PARTICLE ORBITS IN MAGNETIC FIELDS

The latter figure shows how a particle can be turned back by a region of higher field intensity; such a configuration is called a magnetic mirror.

Similarly, energetic protons can be confined by the field accompanying the solar gas jet in fig. 5(B). Once it enveloped the earth, the jet would be in effect a magnetic pipeline along which the protons could travel freely from sun to earth.

Magnetic Implosions.—A simple example of experiments in magnetohydrodynamics is the production of very intense magnetic fields by implosion. A magnetic field is first established inside a cylindrical copper shell (fig. 7). The shell is then made to implode (collapse violently) by symmetrically detonating the surrounding high explosive. As the shell implodes, the field lines are compressed

FIG. 7.—APPARATUS FOR MAGNETIC IMPLOSION

until the magnetic pressure rises enough to stop the fast-moving copper. Fields of as much as 15,000,000 gauss have been produced this way, with corresponding magnetic pressures about 10,000,000 times atmospheric (roughly 100,000,000 lb./in.²).

Controlled Thermonuclear Reactors.—Fusion of atomic nuclei has produced the hydrogen (thermonuclear) bomb; it also offers a practically limitless supply of constructive power, since the fuel comes from water. However, efforts in the 1960s to produce reactors that would control the release of thermonuclear energy were facing difficulties. One aspect of the problem, magnetohydrodynamic instability, is of general interest here.

One proposal for containing the very hot (10^8 ° C.) plasma needed in a thermonuclear reactor is the magnetic mirror sketched in idealized form in fig. 8. The pressure of the plasma is supposed to be balanced exactly by the magnetic pressure on its surface. Such an equilibrium is in fact possible, but this equilibrium configuration is unstable. If initially

FIG. 8.—IDEALIZED MAGNETIC MIRROR CONFIGURATION FOR HOLDING PLASMA

present on the plasma surface, some types of irregularity will grow in time until the configuration is destroyed. Furthermore, there will always be initial surface irregularities arising from imperfect symmetry of the coils that produce the magnetic field and from thermal fluctuations in the plasma itself.

The cause of the instability is easily seen. The magnetic field lines are stretched like rubber bands around the plasma. The innermost field lines tend to go straight down the axis rather than skirt around the plasma. On the other hand, being a gas, the plasma can have any shape as long as its volume is fixed. Thus, by adopting a fluted shape as sketched in an end view in fig. 9, the plasma can preserve its own volume and at the same time satisfy the tendency of the magnetic field lines to shorten as they fill in the troughs of the flutes. The magnetic pressure will then be greater in the troughs than at the peaks and the flutes will become more pronounced. In effect, the plasma will squirt out between the field lines.

There are many different forms of instability. Although a few particles can be kept orbiting in a suitably designed magnetic field for a long time, instability becomes troublesome when the plasma pressure becomes comparable with the magnetic pressure.

MAGNETOMETER, an instrument for measuring a magnetic force. Although the term is often applied to any instrument for measuring the external field caused by a magnet, it has become attached more specifically to instruments for measuring the earth's magnetism. Such instruments can be used for measuring the intensity of one or more components, the direction of the total field vector or one of its components. In practice, usually one of the

FIG. 9.—FLUTE INSTABILITY

intensity components is measured together with the direction of the total field vector, and the field or other components are then computed.

Magnetometers can be classified as (1) absolute magnetometers; (2) relative magnetometers; and (3) variometers. Absolute magnetometers measure the magnetic force without reference to any other standards except those of mass, length and time. Relative magnetometers require comparison with absolute instruments to determine certain fundamental constants that can be determined only with great difficulty, or occasionally not at all; or involve the use of standards of electric current, resistance or voltage. Variometers are used for measuring the variations in the force from time to time between two points in space. A set of variometers for recording time variations of the magnetic field is called a magnetograph.

The absolute magnetometers in use at the majority of magnetic observatories are those that measure the horizontal intensity of the earth's magnetic field by the classical method of C. F. Gauss. Gauss's method permits the measurement of the intensity through two experiments. The first observation is the determination of the period of oscillation of a magnet. The magnet is suspended on a fibre of negligible torsion in a closed housing free from air currents. The period of oscillation is measured, and is a function of the strength of the magnet, its magnetic moment and the strength of the horizontal component of the field. In the second experiment, this magnet is used to deflect a second magnet suspended in a similar manner. Gauss made these deflection observations by keeping the magnet in a fixed position at right angles to the magnetic meridian. Johann von Lamont later revised this procedure, and by means of a theodolite magnetometer could keep the two magnets at right angles during the experiment. In the first experiment, the relationship between the values of the horizontal field and the magnet are expressed as:

$$MH = \frac{4\pi^2 I}{T^2}$$

where H is the horizontal intensity of the earth's field; M is the moment of the magnet; I is the moment of inertia of the magnet and supporting holder; and T is the time of one oscillation.

The moment of inertia of the magnet and its support cannot be computed readily because the shape is irregular and dissimilar materials are used. It is therefore determined experimentally by attaching a cylindrical bar or ring whose moment of inertia can be computed from its dimensions and mass.

In the second experiment, following Lamont's method, the relationship between the field and the deflection angle is:

$$\frac{H}{M} = \frac{2}{r^2 \sin \delta}$$

where H and M are as above; r is the distance between the centres of the two magnets; and δ is the deflection angle. By combining these two equations, the final value is:

$$H^2 = \frac{8\pi^2 I}{T^2 r^2 \sin \delta}$$

In practice, various corrections are applied to allow for the effects of torsion in the fibre, induction in the magnets, coefficients of distribution of magnetism in the magnets, temperature coefficients of the magnet and the deflection bar, etc. Errors are kept down to 0.00008 gauss, where one gamma (γ) is $\frac{1}{100,000}$ gauss.

Relative magnetometers are finding increased usefulness for magnetic survey work and as control instruments at magnetic observatories. The reliability of these instruments has been greatly enhanced by virtue of the new magnetic steels and by the use of modern techniques in measuring electrical quantities on some instruments that operate on electromagnetic principles.

One of the most widely used relative magnetometers, known as the QHM (quartz horizontal magnetometer), was developed by D. La Cour of the Danish Meteorological institute. It consists of a magnet with an attached mirror suspended by a quartz fibre. It operates on the principle of balancing the torque exerted on the magnet by the earth's horizontal magnetic field against the torque

exerted by the fibre when twisted through exactly 2π (360°) radians. The torsion coefficient of the fibre and the moment of the magnet are so related that for the value of horizontal intensity in most latitudes, $HM > 2\pi\phi$ (H is horizontal intensity; M , the moment of the magnet; ϕ , the coefficient of torsion). The suspended system is so arranged that when the magnet is in the magnetic meridian, the mirror is perpendicular to the axis of the telescope attached to the instrument. The image of the scale in the Gaussian eyepiece of the telescope may be viewed through the mirror, and the telescope set perpendicular. To make a measurement, the instrument is first set in the magnetic meridian by bringing the central mark on the scale into coincidence with its image as seen in the mirror. The magnet is left unclamped and the instrument is then rotated slowly through an angle $2\pi + \delta$ to coincidence of the two lines. The instrument is then rotated in the opposite direction through an angle $4\pi + \delta$ to coincidence. The horizontal intensity is then given by:

$$H = \frac{2\phi}{M \sin \delta} = \frac{C}{\sin \delta}$$

C is a constant determined by comparison with standard instruments. Corrections must be applied for the temperature coefficients of the magnet and the quartz fibre.

The QHM is also widely used at fixed observatories for the determination of the magnetic declination by sighting at a mark whose azimuth is known.

A companion instrument of the QHM is the BMZ (magnetometric zero balance) for measuring the vertical intensity. It is similar to the local vertical intensity variometer in principle. The instrument is equipped with two auxiliary magnets, the upper one for establishing the mean value at which the instrument will operate, and a lower magnet used to reach a balanced condition. The indicating or balanced magnet is made from one piece of magnet steel and consists of the magnet, mirror and steel knife-edges. The knife-edges of the magnet rest on cylindrical quartz bearings. A small telescope with Gaussian eyepiece similar to that used in the QHM is used to determine the balanced or horizontal position of the magnet. The observation is made by freeing the balanced magnet and rotating, about a horizontal axis, the lower or turn magnet. The angle through which this lower magnet must be turned to reach a balance is a measure of the vertical intensity. The constants of the instrument also must be determined by comparison with standard instruments. Corrections are applied for the temperature coefficients of the two magnets.

Electromagnetic Magnetometers.—Electromagnetic instruments constitute a large class of relative magnetometers. They all depend upon the comparison of the magnetic field of the earth with the magnetic field produced by a coil through which a measured electric current is flowing. As the electrical standards are accurate to about 1 part in 100,000, they are inferior to the accuracy of standards of length and time. These electromagnetic types of instruments are gradually replacing the older magnetometers and are becoming increasingly important.

The sine galvanometer designed by S. J. Barnett consists of a Helmholtz coil (a system of circular coils giving a uniform field near the axis between them) with the windings in spirals upon a marble cylinder. The dimensions of the coil are accurately measured so that the field produced by this coil can be computed. A small magnet is suspended at the centre of the coil for determining the magnetic meridian as well as the resultant direction after the field from the coil is applied.

In making the measurement, a fixed current is applied and the sine galvanometer is rotated about its vertical axis until the resultant field (*i.e.*, between the coil and the horizontal component of the earth's field) is perpendicular to the axis of the coil. The sine of the angle (δ) between the axis of the coil and the direction of the earth's field is a measure of the horizontal intensity and is given by:

$$H = \frac{Ci}{\sin \delta}$$

in which i is the current and C is the coil constant which has been

accurately calculated from the measurements of the dimensions of the coil.

The Schuster-Smith coil magnetometer, used extensively in England and Canada, is similar to the sine galvanometer except that the current applied to the coil is adjusted so that the field produced by the coil is slightly greater than the horizontal component of the earth's magnetic field. The coil is then turned on its vertical axis nearly 180° with the direction of the earth's magnetic field until the suspended magnet is at right angles to the magnetic meridian. Then $H = H_0 \cos \alpha$, where H is the value of the horizontal component of the earth's field, H_0 is the field produced by the coil and α is the angle between the magnetic meridian and the axis of the coil.

Other electromagnetic instruments have been designed for the measurement of the vertical intensity, such as the instrument designed by D. W. Dye, a counterpart of the Schuster-Smith magnetometer. The coil is a Helmholtz system on a precision-ground marble form, similar to the coils of the instruments mentioned above. The current in the coil is adjusted till the magnetic field at the centre just nulls the vertical intensity. Then $Z = Ci$, where Z is the vertical intensity of the earth's magnetic field; C is the coil constant determined from measurements of the dimensions of the coil; and i is the current. A number of devices have been applied for determining the condition of neutralization of the component being measured. In the Dye coil magnetometer, a small flat coil free to swing about a horizontal axis is used. A comparatively strong alternating current, of frequency equal to that of the mechanical resonance vibration of the coil, is applied to the coil through the suspension wires. This coil acts as a small magnet except that the axis is being continually reversed by the alternating current. The coil will vibrate about the suspension under the action of the vertical magnetic field except when the earth's vertical component has been exactly nulled by the field of the Helmholtz coil.

Another type of null indicator for the electromagnetic instruments is a small coil rotating about a suitable axis within the fixed coil. The output from this coil is usually amplified and the output from this amplifier fed into a suitable detector. This method is capable of high accuracy, since the coupling between the fixed coil and the rotating coil may be calculated accurately to correct for their finite dimensions.

Military requirements of World War II led to the development of a number of devices usable as null detectors which employed a new principle. These detectors depend upon the ability of very weak fields to produce magnetic saturation of certain alloys of iron, nickel and cobalt. If an alternating and symmetrical magnetic force is applied lengthwise to a rod of suitable dimensions and composition, the magnetic flux changes in the rod will be symmetrical. But if there is a small ambient magnetic field parallel to the rod, the flux changes will exhibit pronounced asymmetry. The sensitivity of this effect is sufficiently great that it may be used for the detection of extremely small fields.

Several different methods have been devised for applying this principle to the measurement of magnetic fields. In one of these methods, an alternating magnetomotive force is applied to the permeable material through a coil. Asymmetrical flux changes in the material are revealed by the appearance of voltages in the exciting coil at twice the frequency of the exciting current, voltages which may be filtered out and measured. Another device employs two such units with the axes parallel, side by side or in line, the exciting coils being connected in series opposition. A connection is made between the bridge connecting the two coils and the transformer winding which energizes the coils. When there is no ambient magnetic field, there is no voltage across this bridge, but if there is an ambient field, the flux changes in one element lead those in the other in phase so that sharp voltage peaks occur on each half cycle. In another type of detector, the two elements have a secondary coil wound about them which, when the proper adjustments are made, picks up only the asymmetrical flux changes which appear as voltages across the secondary. Electronic circuits are used with all these types of instruments to amplify and detect the output voltages, although the last type of instrument has been

used successfully with a conventional galvanometer as the detecting member.

Although the greatest sensitivity may be realized when these devices are used as null detectors, they may be used as direct reading instruments to measure the intensity of any component of the field. In most cases, however, the major part of the components of the field to be measured is neutralized by electric currents or balanced out by application of biasing voltages applied to the detecting circuit.

These detectors possess several advantageous characteristics; they comprise no moving parts which are subject to errors resulting from accelerations; they may be mounted in one place and the readings taken in another; they are fast in operation and response; and their outputs may be readily applied to operate various control devices. Electronic control circuits employed to excite the elements and to amplify and detect their outputs are rugged. By suitable amplification small changes in the ambient magnetic field may be made to produce large deflections of rugged recording meters. These characteristics make the induction-type detectors particularly suitable for use on aircraft.

Originally intended for the detection of submarines during World War II, these devices later found extensive application in geophysical prospecting. The great mobility of aircraft and their ability to fly over areas which are accessible for ground surveys only with great difficulty encouraged the use of these induction-type instruments for geophysical surveys. To escape magnetic effects of the plane, the measuring and orienting mechanism is sometimes mounted in a "bird" which is trailed well beneath the plane, the control circuits and indicating meters being mounted within the plane and connected to the bird by electric cables.

In most geophysical surveys conducted on the ground, the vertical component of the intensity is measured since that component uniquely defines the magnetic potential over the area being investigated, subject to certain limitations. Measurements of total intensity do not uniquely define a magnetic potential. However, if the variations in total intensity caused by the magnetic anomaly being surveyed are small relative to the total intensity of the earth's uniform field, a satisfactory solution can be derived.

Nuclear Resonance Magnetometer.—After the end of World War II there was considerable work accomplished on the various nuclear resonance phenomena that are associated with a magnetic field. One of the first instruments developed using these new methods was a nuclear resonance magnetometer, frequently termed a proton precessional magnetometer. The instrument consists essentially of a means of initiating precession of protons having gyromagnetic properties in a magnetic field. Nuclei may have spin or angular momentum, and will act like small gyroscopes. In a constant magnetic field the nucleus, having a magnetic moment may be expected to behave like a compass needle. But because of the spin, the behaviour of the nucleus is slightly more complex. The system has angular momentum and a torque caused by the interaction between the nuclear magnetic moment and the external field. Since the value of the angular momentum of the nucleus is fixed, the only possible change caused by the torque is a change in orientation. This orientation of the angular momentum vector changes steadily, but always maintains a constant angle with the magnetic field, so that the momentum vector moves on the surface of a cone with axis parallel to the magnetic field. This motion is commonly called precession, and is exactly similar to that of a gyroscope acted on by gravity, the axis making a constant angle with the vertical as it precesses. Just as friction or other damping energy in the gravitational field, so the damping forces acting on the nucleus eventually suppress the precession and allow the nuclear magnetic moments to line up with the magnetic field. The time required for these damping forces to act has been called the relaxation time and may be of the order of microseconds or minutes depending on the material used for the sample.

In the nuclear precession magnetometer, the nucleus is polarized in a direction at an angle to the earth's magnetic field. When this polarizing current is suddenly cut off, the protons precess back to the normal (ambient) magnetic field. The frequency of

precession is directly related to the strength of the magnetic field being measured. The instrument consists essentially of a sample containing protons and a coil of wire wound around this sample. The sample may be water or a hydrocarbon such as kerosene. When a strong direct current is applied to the coil, the protons are magnetized or oriented in this new direction. The current is then cut off rapidly, and the protons start precessing back to their normal direction. The coil previously used for polarizing the sample is now connected to an amplifier and suitable electronic counter, and the frequency of precession is measured. This frequency is directly related to the strength of the magnetic field.

$$H = Cf$$

where H is the value of the magnetic field; f is the frequency of precession; and C is a constant.

In 1950 A. Kastler, in Paris, suggested the technique of optical pumping for orienting nuclei and for detecting nuclear magnetic resonance signals in gases at low pressures. This technique has been developed and expanded and is the basis of a type of magnetometer capable of measuring extremely low fields of the order of a few gammas.

The magnetometer consists in its simplest form of a light source, a filter to pass only one of the strong optical lines in the spectrum of the alkali metal being used, a device to circularly polarize the light, an absorption cell and a photocell to monitor the light transmitted through the cell. The light beam is oriented roughly parallel to the magnetic field. Under proper conditions, the atoms will tend to line up with their magnetic moments along the direction of the magnetic field. In this condition, the atoms will absorb less light than normally, and the amount of transmitted light will be greater than if the atoms were randomly oriented. If a radio-frequency field is now applied at right angles to the magnetic field, and at a frequency corresponding to the Zeeman transitions, the atoms will become disoriented, and the amount of light transmitted will decrease. If the applied radio frequency is swept through the resonance value, the resonant frequency will be observed as a dip in the output of the photocell. The above instrument has been used successfully to measure the earth's magnetic field and the results have been of the same order of accuracy as the proton precessional magnetometer or the electromagnetic types of instruments.

MAGNIFICAT, the song of praise of the Virgin Mary in the house of Zechariah (Luke i, 46-55), with which she answered the greeting of Elizabeth: "Magnificat anima mea Dominum" ("My soul magnifies the Lord"). It constitutes the most important canticle of the vespers in the Roman Catholic Church and of the evening office in the Anglican Church; it is used on certain days in the morning office in the Orthodox Church. Besides having been set to plainsong melodies in all the eight church modes, it has received countless settings by later composers.

MAGNITOGORSK, a town of Chelyabinsk oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the eastern flank of the southern Urals, on the banks of the Ural river, about 250 km. (150 mi.) S.W. of Chelyabinsk city. Pop. (1959) 311,101. Just east of the town is Mt. Magnitnaya, rich in magnetite iron ores, and it was to exploit these that Magnitogorsk was founded in 1930, under the first five-year plan; U.S. engineers rendered technical assistance during the early planning. Its vast integrated metallurgical plant is one of the world's largest, with coke ovens, blast furnaces, open-hearth steel furnaces, blooming mills, rolling mills, tin-plating shops, coke-chemical works and a thermal power station. Coking coal is brought from the Kuznetsk Basin (Kuzbass) or from Karaganda in the Kazakh S.S.R. Sub-

sidary engineering industries produce mining equipment and crane and transport parts, while slag is used in cement and glass works. There are also food and other light industries. The Ural is dammed to form a reservoir there, and although the town first developed on the left bank, most subsequent growth has been on the right bank where air pollution is less. Magnitogorsk has pedagogic and mining-metallurgical institutes. The population was 150,000 in 1939, and in 1961 was estimated at 328,000.

(R. A. F.)

MAGNITUDE of a star is the measure of its brightness adopted in astronomy. The higher the number expressing the magnitude the fainter the star. A step of one magnitude corresponds to a decrease in light intensity in the ratio 2.512:1, so that five magnitudes correspond to a decrease in the ratio 100:1. The absolute magnitude of a star is the apparent magnitude it would have if placed at a standard distance of ten parsecs or about 33 light-years.

The bolometric magnitude is an analogous measure of the heat intensity of a star.

See **PHOTOMETRY, CELESTIAL; STAR.**

MAGNOLIA, the common and generic name for evergreen or deciduous shrubs or trees, of the family Magnoliaceae, several species of which are grown for their showy spring blossoms. It includes about 75-80 species, in two centres: about 50 in the old world (Japan to the eastern Himalayas, south to Java) and about 25 in the new world (southern Ontario, the eastern United States, the Greater Antilles and Mexico to Venezuela).

Magnolias have large, simple leaves with stipules. Most magnolias bear showy, fragrant, white to pink or purple, or green to yellow flowers singly at the tips of the branches. The perianth is composed of 9-15 petallike tepals in series of 3 each; the 3 outermost are differentiated as sepals in some species. The numerous stamens and carpels are borne spirally on the elongated floral axis. The conelike fruit is composed of the many carpels, each of which splits along the outer side releasing two scarlet to pink seeds which dangle by slender threads. Essential-oil cells give most tissues of the plant a spicy fragrance when crushed.

Eight species, cultivated as ornamentals in both the United States and England, are native to eastern North America. Five are closely related trees or shrubs with rather large deciduous leaves, clustered near the tips of the branches (whence the name umbrella tree), and large white flowers: *Magnolia fraseri*, of the southern Appalachians; *M. pyramidata*, with a Gulf coast distribution; *M. tripetala*, the original umbrella tree; the spectacular *M. macrophylla*, with leaves up to three feet long (the largest in the genus); and *M. ashei*, restricted to western Florida. Closely related to these are three Asian species, all in cultivation: *M. obovata* (Japan), *M. officinalis* (eastern China) and *M. rostrata* (northwestern Yunnan and adjacent areas). The best-known American magnolia is *M. grandiflora* (bull bay), a handsome evergreen tree, bearing large white flowers, native to the southeastern coastal plain but cultivated in other warm temperate areas. Excepting the tenderer *M. delavayi* (from Yunnan), *M. grandiflora* is the only hardy evergreen species. *M. virginiana* (sweet bay), with small white, very fragrant flowers and leaves whitened beneath, has a wide range along the coastal plain (Massachusetts to southernmost Florida and Texas), and was the first magnolia to be grown in England (1688). *M. acuminata* (called cucumber tree, from the appearance of the young fruits) is a large deciduous tree which occurs from Ontario and New York to Florida, Missouri and Arkansas. Its green to yellow flowers are in striking contrast with those of its only close relative, the purple-flowered *M. liliflora* of China.

BY COURTESY OF UNITED STATES DEPARTMENT OF AGRICULTURE

STAR MAGNOLIA (*MAGNOLIA STELLATA*) IN BLOOM

More than half of the Asian magnolias are evergreen trees and shrubs of the tropics, and only about 20 are suitable for cultivation in temperate areas. Among the hardy and showy ornamental species are the Chinese *M. denudata* and *M. liliflora* and the Japanese *M. stellata*, *M. kobus* and *M. salicifolia*. Unfortunately, *M. sprengeri*, *M. sargentiana* and *M. campbellii*, among the most beautiful trees in the genus, are far less hardy. In all of these species, flowering occurs before the leaves appear, in contrast with the American species which flower with or after the unfolding of the leaves.

J. HORACE MCFARLAND CO.

LARGE WAXY BLOSSOMS OF A HYBRID
MAGNOLIA (MAGNOLIA SOULAN-
GIANA)

No wild hybrids of *Magnolia* have been found, although a number of garden hybrids are known. Probably the most widely cultivated of any of the Asian group is *M. soulangiana*, a hardy and vigorous hybrid (originated near Paris, 1820) of the white-flowered *M. denudata* and the purple *M. liliflora*.

Magnolias prefer well-drained but moist, rather loamy, slightly acid (pH 6) soil. Propagation is by layers, cuttings, grafts or seeds. The seeds have a short period of viability, especially if allowed to dry out, and usually a period of moist cold is necessary to promote germination. Attempts to send seeds from Asia to England were mostly unsuccessful until the practice of coating the seeds with paraffin was tried; the storage and transport of seeds in bags of polyethylene film is a more modern development.

Much attention has been focused on *Magnolia* as one of the most primitive of living flowering plants, particularly on account of the woody habit, the numerous, free and spirally arranged floral parts, the primitive stamens and the single-grooved pollen grains. Although the group is undoubtedly ancient (more than 80 fossil "species" have been described) and formerly had a much wider distribution in the northern hemisphere, a number of other extant flowering plants show evolutionarily much more primitive structures; e.g., some of the species of the genus *Drimys* (of the family Winteraceae).

(C. E. W.)

MAGNUS, the name of many kings of Norway.

MAGNUS I OLAFSSON THE GOOD (1024–47), king from 1035, was an illegitimate son of Olaf the Saint; he was named after Charlemagne (Old Norse Karla-Magnús). Taken by his exiled father to Russia at the age of four, he remained there until 1035, when the chiefs of Norway, chafing under the rule of Sweyn (Svein), son of Canute the Great of Denmark, summoned Magnus to Norway and made him king.

After Canute's death in 1035, his son Hørda-Knut, or Hardicanute (q.v.), became king of Denmark and laid claim to the throne of Norway; but it was agreed that if he or Magnus died, the other should rule both kingdoms. When Hardicanute died in 1042, Magnus thus became king of Denmark. He appointed Canute's nephew Sweyn Estrithson as viceroy and himself defended Denmark against the incursions of the Wends or Slavs, whom he crushed in the battle of Lyrskog in South Jutland (1043). Sweyn and his Danish supporters afterward rose against Magnus.

In 1046 Magnus and his uncle Harald Hardraade, who had come home from Constantinople, agreed to share the kingdom. They

attacked Denmark, but Magnus died during the campaign on Oct. 25, 1047.

MAGNUS (c. 1048–69), son of Harald Hardraade, succeeded with his brother Olaf III in 1066, but died in April 1069.

MAGNUS II BARFOT or BARELEG (c. 1073–1103), succeeded his father, Olaf III, in 1093. He set off for Orkney in 1098 and then raided the Hebrides, the Isle of Man and Anglesey, where he defeated the Norman earls Hugh of Chester and Hugh of Shrewsbury. In later years he engaged in campaigns against Ingi, king of the Swedes, but their differences were resolved in 1101 and Magnus married Ingi's daughter Margaret. In 1102 Magnus embarked on another expedition to the west. He visited the Hebrides and Man, but fell fighting in Ulster in Aug. 1103. It was said that his nickname "Bareleg" was given because he affected the kilt.

MAGNUS III THE BLIND (c. 1115–39), son of Sigurd I Jorsalafar, succeeded to the throne jointly with Harald IV in 1130. In 1135 Harald seized Magnus, maimed and blinded him and put him in a monastery. Later released, Magnus was killed in battle in 1139.

MAGNUS IV (1156–84), the son of Erling the Crooked and Kristin, daughter of Sigurd Jorsalafar, was made king on the death of Ingi I in 1161. His coronation, the first in Norway, took place in Bergen in 1163. His father was the effective ruler until he died in 1179. Magnus then defended his title against his rival Sverre until he was defeated and killed at Norefjorden on June 15, 1184.

MAGNUS V LAGABOETER or LAW-MENDER (1238–80), succeeded his father in 1263. One of his first acts was to make peace with the Scots (treaty of Perth, 1266), ceding the Hebrides and Man to Scotland. He introduced important legal and constitutional reforms both in Norway and in Iceland. He died in Bergen on May 9, 1280.

MAGNUS VI ERICSSON (1316–74) was the son of Haakon V's daughter Ingebjörg or Ingeborg and of Eric, brother of the Swedish king Birger (d. 1318). Because of a dynastic accident, Magnus was proclaimed king of both Norway and Sweden when Haakon V died in 1319. Government was conducted at first by his unpopular mother, later by a regent. Magnus assumed his powers in Norway in 1332. He showed greater interest in Sweden than in Norway, which he left for long periods without government; and in 1343 his infant son Haakon VI was designated king of Norway. Haakon VI attained his majority in 1355, but Magnus remained king of Sweden, though he had many enemies. He died on Dec. 1, 1374.

(G. T. P.)

MAGNUS, OLAUS (Swedish OLAF MANSSON) (1490–1557), Swedish ecclesiastic and author of an influential history of Scandinavia, was born at Linköping in Oct. 1490. A Catholic priest, he went to Rome in 1523, during the Swedish reformation, and thereafter lived in exile, first in Danzig and later in Italy, with his brother Archbishop Johannes Magnus (1488–1544), on whose death he was appointed Catholic archbishop of Sweden. After 1549 he was also director of St. Brigitta's, a religious house in Rome. Magnus died in Rome, Aug. 1, 1557.

Olaus Magnus' *Carta marina* (1539) was the first detailed map of Scandinavia with any pretensions to accuracy. His foremost work, however, is the *Historia de gentibus septentrionalibus* (1555), a history of the northern peoples inspired by humanist historiography and imbued with patriotic warmth, which gives a picture of the countryside and people of Sweden on the threshold of a new era. It appeared in many editions and translations during the 17th century—the first English translation being the *History of the Goths, Swedes and Vandals* (1658)—and for long influenced the European idea of the Scandinavian people.

(S. H. L.)

MAGNUS MAXIMUS: see MAXIMUS.

MAGNÚSSON, ÁRNI (1663–1730), Icelandic antiquarian and philologist, who built up the most important collection of early Icelandic literary manuscripts, was born at Kvennalækur on Nov. 13, 1663, and matriculated at the University of Copenhagen in 1683. He graduated in theology in 1685, but was interested chiefly in the early history and literature of Scandinavia. He traveled extensively in Norway, Sweden and Iceland, collecting books and manuscripts. In 1697 Magnússon was appointed secretary of the secret archives and, in 1701, professor of philosophy and Danish antiquities. In 1702 he went to Iceland on a royal

mission to value estates and report on economic conditions. Magnússon was engaged on this task until 1712, and spent much of the time gathering Icelandic manuscripts. His collection was sent to Denmark in 1720. A large part of it perished in the fire of Copenhagen (1728), but the remainder passed to the University of Copenhagen, where it is still housed. Magnússon's published works were few and of minor importance. He died at Copenhagen on Jan. 7, 1730.

See F. Jónsson, *Arni Magnússon's Levned og Skrifter* (1930); H. Bekker-Nielsen and O. Widding, *Arne Magnússon* (1963; with summary in English). (G. T.-P.)

MAGO (MAGON), a common Carthaginian name, shared by a number of important members of the aristocratic Magonid family. The first of these flourished between 550 and 500 B.C. and was responsible for reforms in the army and for extending the influence of the Carthaginians in Sardinia, the Balearics and possibly Spain (see *CARTHAGE: History*). A second Mago took part in the war against Dionysius I of Syracuse (396 onward), and another took part in an unsuccessful Punic expedition against Syracuse in 343. Another admiral of the name Mago was sent to Rome in the spring of 278 with 120 ships to persuade the Romans to continue the war against Pyrrhus (*q.v.*) and to make a treaty with Carthage.

The most famous of the bearers of this name was, however, the youngest of the three sons of Hamilcar Barca. He accompanied his brother Hannibal (*q.v.*) to Italy and held important commands in the great victories of the first three years of the Second Punic War. After the battle of Cannae (216), he was sent to help his other brother, Hasdrubal, in Spain. There he carried on the war with varying success, but was defeated in 206 by Scipio Africanus at the battle of Ilipa (*q.v.*). After staying for some time in Gades (Cadiz), he carried the war into Liguria; he was finally defeated in Cisalpine Gaul in 203 and died of wounds on the return voyage to Carthage.

Mago was also the name of the author of a great work on agriculture written in Punic in 28 volumes. Captured by the Romans after the destruction of Carthage, it was taken to Rome and translated by order of the senate and was regarded as an authoritative work of reference for Roman agriculture and viticulture.

See B. H. Warmington, *Carthage* (1960). (Wm. C.)

MAGPIE, the common name for several strikingly coloured birds of the crow family (*Corvidae*); with the jays, magpies comprise the subfamily *Garrulinae*. They are world-wide in distribution. The commonest species in the northern hemisphere is the black-billed magpie (*Pica pica*), well known in western North America and in all of Europe. It is about 20 in. long, including the 10-in. tail, and is distinctively marked with stark white shoulders, flanks and belly against a deep glossy black body and wings; the wedge-shaped tail, which streams out behind the body in flight, is lustrous with greenish and purplish iridescence.

The nest is a large, elaborate structure, placed either in trees or bushes. Its foundation consists of stout sticks, turf and clay, made into a deep, hollow cup, plastered with earth and lined with fibres; around this is erected a basketlike weave of thorny sticks, forming a dome over the nest, and leaving a hole in the side for entrance and exit. Within the nest are laid from six to nine eggs of a pale bluish-green colour, freckled with brown and blotched with ash. The magpie, in common with the raven, the jay and many birds of prey, has a remarkable capacity, when its mate is killed, for obtaining a new mate within a day or two.

The yellow-billed magpie (*Pica nuttalli*), found resident in California, is similar in most respects to *P. pica* except for the bright yellow bill and bare yellow skin around the eyes. Other more exotic species include the Asian red-billed blue magpie (*Urocissa erythrorhynchos*), the size of a pigeon, with blue and black col-

ouring and central tail feathers up to 17 in. long, blue with white tips. The green magpie (*Kitta chinensis*) is another red-billed, long-tailed species of Asia.

MAGSAYSAY, RAMÓN (1907–1957), Philippine soldier and political leader who as secretary of defense and president defeated the communist-led Hukbalahap (Huk) movement after World War II, was born on Aug. 31, 1907, at Iba in Zambales province on Luzon. He worked his way through the University of the Philippines at Manila (1927–31) and José Rizal college, from which he received a degree in 1933. Rising from his first job as an automotive mechanic, he became by 1941 branch manager (later general manager) of a transportation company.

He fought with U.S. forces against the Japanese until the surrender of Bataan in April 1942, when he joined the guerrilla forces in Zambales province. After the reconquest of the islands by U.S. troops Magsaysay was named military governor of Zambales. Released from military service, he was elected to two terms in congress as a member of the Liberal party (1946–50). In 1950 Pres. Elpidio Quirino appointed him secretary of defense. The Huks, then at the height of their power, derived much support from the peasants, who felt the local constabularies oppressed them and were representatives of the landlords. Magsaysay replaced the constabulary with army units, reformed the army and fought the Huks, offering them "complete force or complete fellowship"; to those who surrendered he gave land and tools. In 1953 he resigned as secretary of defense and also left the Liberal party. He joined the Nationalist party, charging President Quirino with obstruction of his anti-Huk campaign and with a corrupt administration.

The Nationalist party nominated Magsaysay to oppose Quirino for the presidency; Magsaysay won the election and was inaugurated Dec. 30, 1953, for a four-year term. He also served as secretary of defense until May 1954, when the surrender of the Huk leader Louis Taruc climaxed the anti-Huk campaign. Despite Magsaysay's great personal popularity, congressional and intra-party opposition slowed the progress of his program of land and governmental reform. His opponents considered his friendship with the United States extreme, but he held firm in foreign policy. In July 1955 congress gave the president power to break up large landed estates and carry out basic land reform; in August a Nationalist party convention completely endorsed the president's program and nominated a slate of candidates to remove the president's strongest opponents in congress. This slate won in November, but congressional opposition to his reform measures continued. Magsaysay died in an airplane crash on March 17, 1957, while returning from Cebu city to Manila, and was succeeded by Carlos P. Garcia, vice-president and foreign minister.

See Carlos P. Romulo and Marvin M. Gray, *The Magsaysay Story* (1956).

MAGWE, a district and division of Upper Burma. The division includes the districts of Thayetmyo, Minbu, Magwe and Pakokku. Pop. (1962 est.) 2,137,029. The district has an area of 3,724 sq.mi. and a population (1962 est.) of 711,449 and lies entirely east of the Irrawaddy in the centre of Burma's Dry Belt. Along the river the land is undulating, with a marked development of river terraces. It is seamed with nonperennial stream courses or *chaungs* which come down in flood after sudden storms but are normally dry and give rise to some badland type of country. Two such streams are the Yin and Pin; only the Yanbe is perennial. Where the soil is suitable, millet, sesame, peanuts and some rice are grown, but there are large areas of semidesert scrub. In the heart of the district is a broad plain, extensively cultivated, through which a branch railway from Pinyinmana was constructed. The eastern part of the district is occupied by valuable forests at the northern end of the Pegu Yoma. Magwe town is on the Irrawaddy nearly opposite Minbu but is overshadowed by the oil-field town of Yenangyaung. The district also includes the Singu-Chauk oil fields. (L. D. S.)

MAGYAR, the name of the dominant people of Hungary. The article HUNGARY surveys their origin and history, and the article HUNGARIAN LANGUAGE describes the Magyar language, which belongs to the Finno-Ugric family. They themselves call

JOHN WARRENHAM
BLACK-BILLED MAGPIE (*PICA PICA*)

Hungary Magyarország ("land of the Magyars"); but this name before World War I was sometimes reserved to denote historic Hungary, that is to say the lands under the crown of St. Stephen (including Slovakia, the Banat and Transylvania) without the theoretically distinct kingdom of Croatia or Croatia-Slavonia. Croatia, however, was understood to be comprised with historic Hungary under the name Magyarbirodalom ("realm of the Magyars").

Before World War I, under the Austro-Hungarian dual monarchy, the Magyars formed barely half of the population of the Magyarország (without Croatia-Slavonia), numbering 9,345,000 out of 20,890,000 (44.7%) at the census of 1910. At the time of the same census, however, the Magyars living within the frontiers later to be drawn for the postwar Hungary under the treaty of Trianon (*q.v.*) numbered 6,250,000 out of a total population of 7,540,000. Still according to the census of 1910, there were 955,000 Magyars in the territory that went to Czechoslovakia under the treaty of Trianon, 1,550,000 in the territory that went to Rumania and 560,000 in the territory that went to Yugoslavia.

After World War II, when the frontiers of Hungary, expanded during the war, were reduced again to those of the treaty of Trianon with the further loss of a bridgehead south of Bratislava, there were 425,970 Magyars in Czechoslovakia (census of 1961), 1,587,675 in Rumania (census of 1956), 502,175 in Yugoslavia (census of 1953) and 149,000 in the Ukraine (*i.e.*, in Sub-Carpathian Ruthenia; census of 1959). In Hungary according to the census of 1960 there were 8,657,102 Magyars (92.8%) out of a total population of 9,977,870.

See also references under "Magyar" in the Index.

MAHABAD (MEHABAD; formerly SAUJBUQA or SAVAJ-BOLAGH), a town and *shahrestan* (district) in West Azerbaijan *ostan* (province), Iran, south of Lake Rezaieh. The population of the *shahrestan* in 1956 was 233,751. In 1959 Iran's districts were reorganized resulting in an adjusted pop. of 162,511. Many of the inhabitants pitch tents in summer and farm the hilly land during the winter from many tiny villages. Ethnographically the district forms part of Iranian Kurdistan, comprising the bulk of the Mukri tribal areas. The town (pop. [1956] 20,332) stands in a fertile narrow valley, at 4,272 ft. above sea level. It is connected by road with Tabriz, Rezaieh and Mosul, Iraq, via Rawanduz. The town and district suffered greatly under repeated political strife. The area formed a short-lived, Soviet-backed autonomous republic after World War II. Mahabad is now in Iranian hands but retains its position as a centre of Kurdish nationalism. (H. Bo.)

MAHABHARATA, "the great (tale) of the descendants of the prince Bharata," and one of the two great epic poems of India, is a vast compilation of over 100,000 couplets (about eight times the length of the *Iliad* and *Odyssey* combined). The central matter of the epic, the struggle for supremacy over Kurukshetra (with its capital at Hastinapur, northeast of the modern Delhi) between the two rival families, the Kauravas and the Pandavas, is based on historical events which took place not later than the 10th century B.C. The Mahabharata contains numerous episodes, emphasizing themes in the main narrative, which have gained individual renown, such as the tales of Nala and Damayanti, of Savitri, and the discourse, the Bhagavad Gita (*q.v.*). Traditionally the sage Vyasa ("the arranger") is the author, though it is more likely that he compiled existing material, which reached its present form by A.D. 400. See also SANSKRIT LITERATURE.

MAHALLAH AL KUBRA, AL, a textile manufacturing town of lower Egypt. It is situated in the east of Al Gharbiyah *muhafazat* (governorate) on the Bahr Mallah channel, 8 km. (5 mi.) W. of the Damietta branch of the Nile river and 113 km. (70 mi.) N. of Cairo by rail (75 mi. by road). Pop. (1957) 149,590, (1962 est.) 188,000. Its growth from a small market town took place after 1927, when the Misr group established there a cotton textile mill, superseding much domestic hand-loom weaving. Al Mahallah al Kubra is the centre of Egypt's textile industry and accounts for about 40% of the country's mechanized spinning and weaving production. Besides producing cotton goods (including dyeing and printing), the works manufacture rayon, flannel-

ette, woolen cloth, blankets, linen, knitwear and hosiery; the payroll is about 20,000. The company has created a model workers town with wide tree-lined streets and housing estates, quite unlike older Egyptian towns, while the mills are equipped with all modern recreational and welfare facilities.

There are also cotton ginneries, and mills for rice and flour. The main railway from Cairo to Damietta links Al Mahallah al Kubra with the capital of the governorate, Tanta, 26 km. (16 mi.) S.S.W. (A. B. M.)

MAHAN, ALFRED THAYER (1840-1914), U.S. naval officer and historian, an early exponent of sea power, was born on Sept. 27, 1840, at West Point, N.Y., where his father was professor of military engineering at the U.S. Military academy. Columbia college and the U.S. Naval academy at Annapolis, Md., qualified him for the U.S. navy, in which he served 40 years. He saw active service in the Civil War and when 21 designed a "mystery ship" and volunteered to command it. After acting as lecturer on naval history and strategy at the Naval War college, he became its president in 1886. An indefatigable student with a prodigious memory, he steeped himself in the strategy of Antoine Henri Jomini, Napoleon and Nelson and made critical analyses of the conclusive battles of the world on land and sea. *The Influence of Sea Power Upon History, 1660-1783*, published in 1890, was inspired by a conviction that the historic significance of the control of the sea had never been fully revealed. It was followed in 1892 by *The Influence of Sea Power Upon the French Revolution and Empire, 1793-1812*. These classic works were widely acclaimed by naval men, statesmen and scholars and have been credited with stimulating the growth of navies between 1900 and 1914. No previous writer had so convincingly argued the case for the dominating influence of sea power. The famous trilogy was completed by *The Life of Nelson* in 1897.

Mahan was recognized as an authority on naval strategy, especially in Great Britain, and his doctrines have been said to have governed the naval political thought of the world. Degrees were conferred upon him by Oxford and Cambridge universities in 1894 and later by leading U.S. universities. He commanded the cruiser "Chicago" in European waters, 1893-95, and served on the naval war board during the Spanish-American War of 1898 and as delegate to The Hague peace conference in 1899. In 1900 he was awarded the Chesney gold medal for his three works, which were translated into several foreign languages. He was president of the American Historical association in 1902 and chairman of a commission on naval affairs in 1908.

Mahan, who excelled as a strategist rather than as a tactician, attempted chiefly to make clear the paramount importance of the sea as a decisive factor in history. He analyzed the elements of sea power in all its bearings, military, national, territorial and commercial. With masterly touch he dissected the strategic features of the Caribbean. He stressed the interdependence of the military and commercial control of the sea and held that commerce dominates war. In *The Interest of America in Sea Power, Present and Future* (1897) and in most of his 20 volumes he sought to arouse his countrymen to a realization of their maritime responsibilities. He doubted the infallibility of arbitration in international disputes and in Anglo-U.S. naval supremacy saw the surest hope of peace.

Mahan died on Dec. 1, 1914, having foretold the defeat of the Central Powers and the surrender of the German navy. Discussion of sea power compels recourse to his works, which are invaluable to students of international affairs. (See SEA POWER.)

For a complete list of works and bibliography see Charles Carlisle Taylor, *The Life of Admiral Mahan* (1920). (C. C. TAYLOR)

MAHANADI ("the Great River"), a river of India, rises 25 mi. S. of Raipur town in the wild mountains of the Bastar district in Madhya Pradesh. At first an insignificant stream, taking a northerly direction, it drains the eastern part of the Chhattisgarh plain. Above Seorinarayan it receives its first great affluent, the Seonath; thence flowing for some distance due east, its stream is augmented by the drainage of the hills on both north and south. It then turns south and, struggling through masses of rock, flows past the town of Sambalpur to Sonpur. Just above Sambalpur

is the site of the Hirakud dam which India claims as the world's largest earth dam, completed in 1957 and resulting in a man-made lake 35 mi. long. From Sonpur the Mahanadi pursues a tortuous course among ridges and rocky crags toward the range of the Orissa hills (the Eastern Ghats), which it pierces by a gorge flanked by forest-clad slopes. There the Tikarpara dam was constructed. After the opening of the Bengal-Nagpur railway, the Mahanadi was little used for navigation. It reaches the Orissa deltaic plain at Naraj, about 7 mi. W. of Cuttack town, and after traversing Cuttack district from west to east and throwing off numerous branches, it enters the Bay of Bengal at False point by several channels.

The Mahanadi has an estimated drainage area of 75,000 sq.mi. It is also one of the most actively depositing streams in the sub-continent of India. Flow in the delta before the construction of the modern dams varied from a maximum of approximately 2,000,000 cu.ft. per second to 1,125 cu.ft. per second in drought. Liability to flooding was one of the greatest hazards to the region round the delta but the deposition of silt which results from the flooding is a major asset. There has long been a series of canals in the delta, designed primarily for flood control and for protective irrigation in years of deficient rainfall. All these have been improved. See also ORISSA. (L. D. S.)

MAHAR, a group of over 50 endogamous castes in Maharashtra state, India. In the 1960s the Mahar community of several million comprised roughly 9% of the total population of Maharashtra (*q.v.*) and is by far the largest, most widespread and most important of all scheduled castes (formerly untouchables) in the region.

Traditionally, Mahars supplied one of the 12 hereditary officials in the distinctive Maharashtrian village organization. Mahar duties included those of village watchman, policeman, messenger and guide; adjudicator of boundary disputes; street sweeper and remover of carcasses. As payment, Mahars received cash, a share of village grain and produce and scavenging rights. Sometimes they received land, but they have never been primarily a cultivating community. Consequently, in modern times Mahars have found it relatively easy to migrate to urban centres (Bombay, Nagpur, Poona and Sholapur) and to become industrial labourers, railway workers, mechanics, bus and truck drivers.

The most eminent 20th-century Mahar, Bhimrao Ramji Ambedkar (*q.v.*), stimulated his caste-fellows to militant political consciousness and to great educational improvement. Before his death in 1956, Ambedkar led over 500,000 Mahars into Buddhism in an effort to escape the disadvantages of being low-caste Hindus. See also CASTE (INDIAN); UNTOUCHABLES. (M. L. P. P.)

MAHARASHTRA, a state of the Republic of India, with Bombay as its capital city. It has, according to the redefined boundaries laid down in the Bombay Reorganization act, 1960, an area of 118,717 sq.mi. and a population (1961) of 39,553,718. When India became independent in 1947, the province long known as Bombay Presidency became Bombay state. The following year a number of former princely states (notably Baroda) were merged into the new state, and on Nov. 1, 1956, the major reorganization of the states of peninsular India resulted in the addition of large parts of the former Hyderabad and Madhya Pradesh. From 1956 to 1960, with an area of 190,668 sq.mi. and a population of 48,265,221 (1951), Bombay was the largest state in the republic and second in population. In the north it comprised most of the Gujarati-speaking peoples and in the south most of the Marathi-speaking. It was on this linguistic basis that the state was split into two on May 1, 1960, with Gujarat in the north and a state that was at first named Maharashtra in the south. The latter resumed the name Bombay a few weeks later, but before the end of the year, despite opposition, the central government declared Maharashtra the official name. As now defined, with minor boundary adjustments, this comprises 26 districts, which are, in effect, all those parts of India where Marathi is the dominant language. It stretches along the west coast between the former Portuguese territories of Damão and Goa, comprising an area known as the Konkan (*q.v.*), and far inland beyond Berar and the city of Nagpur to include the dis-

tricts of Bhandara and Chanda. It is bordered by Gujarat and Madhya Pradesh in the north and east and by Andhra Pradesh and Mysore on the south.

Physical Features.—Maharashtra comprises the coastal strip backed by the high crest of the Western Ghats beyond which is a rolling plateau with flat-topped hills indicating the presence of the successive lava flows, almost horizontal, of the Deccan basalts, formerly known as traps. The lavas cover practically the whole surface; the underlying complex of metamorphic rocks is rarely seen. Spurs from the Western Ghats reach the coast, which renders north-south communication difficult; neither motor road nor railway has been constructed through the west coast districts south of Bombay city. The coast is rock-bound and dangerous when the southwest monsoon is blowing onshore. There are havens for small vessels, but there is only one major inlet, that protected by the island on which Bombay city has been built and which is one of the most magnificent and spacious harbours of Asia.

The climate shows the typical monsoon regime of cool dry season with light northeasterly winds from the land (about November to February), the hot dry season of March, April and May followed by the rainy season when the southwest monsoon blows directly against the west coast and Western Ghats. Apart from preliminary showers (mango showers) in May and early June, the rains break suddenly about mid-June. The Konkan is very wet; no part receives less than 80 in., while Mahabaleshwar, in the Western Ghats, with an annual average of more than 250 in., has one of the highest recorded rainfalls in the world. The winds lose their moisture in rising to cross the Ghats, and eastward on the plateau the average rainfall declines rapidly so that over most of the plateau districts it is less than 40 in. a year. The coastal districts enjoy equable temperatures, monthly averages ranging, as at Bombay city, only a few degrees above or below 27° C. (80° F.). A range of more than 7° C. between day and night temperatures is unusual. Stations like Poona, high up on the plateau but sufficiently near its edge to get a good rainfall, benefit from the elevation to be cooler throughout the year but remain equable. Mahabaleshwar, at 4,534 ft., has long been used as a hill station. Eastward on the plateau, with the lower rainfall, both daily and annual ranges of temperature increase.

The wet coastal districts have swift mountain torrents, sometimes with spectacular waterfalls when in spate but greatly hindering land communication and useful mainly for floating down timber. Except in the extreme north, where it is trenced by the westward-flowing Tapti, most of the plateau is drained by seasonal, eastward-flowing tributaries of the Godavari and Krishna in broad open valleys. Many rise very close to the edge of the plateau, the crest of the Western Ghats, which varies from 2,500 to 4,500 ft. in height, with some points exceeding 5,000.

The basaltic lava flows of the plateau break down into the famous regur or black cotton soil of India. It is a heavy, dark, almost black, clayey loam, which holds moisture well and is especially suited to Indian varieties of cotton and to dry zone grains. Some irrigation is practised in the broad open valleys, but care has to be taken in the use of irrigation water as the soil easily becomes a pasty mud.

The natural vegetation of the state reflects in the main the amount of rainfall. There are evergreen rain forests of large trees on the wet western slopes of the Ghats, giving place to a somewhat narrow but valuable belt of the monsoon forests, leafless in the dry season but including teak and the useful sal tree (*Shorea robusta*), and then eastward to the scrub forests and savanna lands so typical of much of the plateau. (L. D. S.)

History.—The present state comprises more than the ancient Maharashtra, which did not include the Konkan coastal strip and did not stretch so far south as Pandharpur, the celebrated Vaishnava shrine, nor as far east into the Deccan. For the history of early dynasties who ruled over this area between the 6th and 10th centuries A.D., see CHALUKYA; RASHTRAKUTA. By the beginning of the 13th century Maharashtrians or Mahrattas, speaking the forerunner of Marathi, were infiltrating into regions occupied previously by Telugu- and, more notably, Kanarese-speaking peoples. With the exception of the Konkan, which tended to be rich and

easygoing, all Maharashtra, including the Ghats, was hard and severe, and the earliest ruling families of which there is any record were occupied largely in invading and attempting to exploit wetter, easier regions, such as Gujarat, Vengi and the Tamil country. Patronage of religion, letters and architecture was virtually unknown until in the 13th century, under the Yadavas, success outside Maharashtra brought an accumulation of resources. Poona was, and remains, in the cultural heart of the country. Under the Yadavas, too, Maharashtrian schools of Vaishnavism became prominent.

After the defeat of the last Yadava by the troops of the sultan of Delhi in 1310, a period of unrest followed, during which Maharashtra was partitioned between the sultanates of Ahmednagar and Bijapur, two of the successor states of the Bahmani (q.v.) empire. When the sultanates were absorbed by the Moguls, some Maratha officials attempted to carve out separate fiefs and to challenge Muslim authority. For the rise of Hindu autonomy in this area and for the history of the period of Maratha ascendancy and of the Maratha Wars, see MARATHA.

The essence of Maharashtra has been its possession of a common language, and an active, restless people. Participation in Hindu Sanskrit culture came rather late but was embraced the more fervently for that reason. The feelings of independence, and even superiority to the inhabitants of the easier, wealthier regions in the north, west, east and southeast, can be explained on historical grounds. The neighbours to the south were equally poor but not equally successful. Maharashtrians show no great aptitude for commerce and have no great artistic traditions, but the blending of cultures, particularly in Bombay and similar centres, has ushered in a more fruitful era. (See also INDIA: History.)

(J. D. M. D.)

Population, Administration and Social Conditions.—At the 1961 census the population was 39,553,718. There are many Adibasi communities in the state, like the Agaris, the Warlis, the Katkaris, the Thakurs of the Thana and Kolaba districts, the Bhils of Dhulia and the Gonds of Vidarbha, who live in dense forests or on the mountain perches of the Western Ghats.

The state is divided into 26 districts grouped in 4 divisions: Jalgaon and Dhulia (formerly East and West Khandesh); Nasik, Thana, greater Bombay, Kolaba, Ratnagiri (Bombay division); Ahmednagar, Poona, Satara, Sangli, Kolhapur, Sholapur (Poona division); Aurangabad, Parbhani, Bhir, Osmanabad, Nanded (Aurangabad division); Buldana, Akola, Amravati, Yeotmal, Wardha, Nagpur, Chanda, Bhandara (Nagpur division).

There are more than 380 towns and nearly 36,000 villages in the state. The more important cities and towns with their populations at the 1961 census, are as follows: Bombay (4,146,491); Nagpur (643,659); Poona (597,562); Sholapur (337,583); Kolhapur (187,442); Nasik (131,103); Akola (115,760); Amravati (137,875); Ahmednagar (119,020) Ulhasnagar (107,760); Malegaon (121,408); Thana (101,107). (S. Ch.)

With about one-eighth of the population attending educational establishments and about 30% of the people literate, Maharashtra is one of the educationally advanced states of India. In 1958-59 there were 45,000 schools and higher educational institutions, including five universities—Bombay, Nagpur, Poona, Marathwada and Shreemati Nathibai Damodar Thackersey Women's university. Free compulsory primary education for children between the ages of 7 and 11 is available in all villages with a population of more than 1,000 in western Maharashtra. The Marathi (q.v.) language and its various dialects are widely spoken.

Nearly 900 hospitals and dispensaries generally provide free medical aid. Under the contributory social insurance plan many industrial workers in greater Bombay and the Vidarbha region are protected against sickness, maternity and employment injury.

Maharashtra is one of the pioneer states in providing welfare facilities for children, including the care and rehabilitation of juvenile delinquents and destitute and neglected children. Welfare centres offer recreational, cultural and educational facilities to industrial workers. Under a Sarvodaya plan, free educational facilities and medical aid are available to backward classes and tribal people. (S. B. L. N.)

The Economy.—Rice, which occupies about 10% of the cultivated area, is grown mainly in the small alluvial basins that lie between the hills of the west coast; on the plateau cotton sometimes predominates, followed by wheat on the better lands, but the great staples in the poorer parts are jowar and bajra. Oilseeds, fodder and grain occupy large areas. Sugar cane is more local, and coconuts are typical only of the coast. The Konkan is famed for its mangoes and cashew nuts. Forests of the varied types mentioned in *Physical Features* cover large areas; products include timber, fuel, sandalwood, bamboos and grasses.

Production of manganese ore is of major importance. Other minerals include limestone and salt, which is produced in some coastal areas by evaporation.

Maharashtra can claim to be the most industrialized state in India, with about 8,000 registered factories employing two-thirds of 1,000,000 workers. Bombay city is the great centre, but the former dominance of the cotton textile industry has given place to a marked diversification, with general and electrical engineering, a considerable motion-picture industry, the making of rayon fabrics, ceramics, glassware (especially at Ogalewadi), drugs, chemicals, antibiotics (at Pimpri, near Poona), soap, sugar and agricultural implements and pumps (at Kirloskarvadi) and the refining of oil (at Thana). There are government printing works at Nasik and hydroelectric plants at Khopoli, Bhivpuri, Bhira and Koyna and a thermal power station at Trombay.

With an excellent harbour and highly developed industries, Bombay city is an important trading entrepôt for the whole of India. To the east of the city lies one of the relatively easy passes through the Ghats, which facilitated the early construction of railway links with other parts of India. Under the railway grouping of 1947 Maharashtra is served by three of the systems: the Western railway northward into Gujarat, the Central from Bombay eastward and the Southern southeastward to Madras. The state has more than 2,600 mi. of railway line. The use of motor transport as a feeder to the railways continues to extend with the metaling and tarring of roads. The Konkan is the only part of the state not well served with rail and road. Bombay city has an international airport, and much use is made of local air services. (L. D. S.)

MAHASU, a district of Himachal Pradesh, India, was formed by the integration of several small hill states, and is wholly mountainous, reaching elevations of about 22,000 ft. Area 2,171 sq. mi. Pop. (1961) 358,969. It is drained by the tributaries of the Jumna (Yamuna) and the Sutlej. The latter enters from Tibet, runs in a southwesterly direction, forming the boundary between Mahasu and Mandi districts for a short distance, then winds through Bilaspur on its way to Punjab. Dense forests of pine, silver fir and cedar occur on the lower slopes. The people depend mainly on agriculture. Wheat, barley and maize (corn) are the chief crops. Solan (pop. [1961] 6,564) has a brewery and a government college affiliated to Punjab university. The district is divided into eight *tehsils* and two sub-*tehsils*. Chini *tehsil*, bordering Tibet and a small portion of the Rampur *tehsil* were formed into Kinnaur district on May 1, 1960. (S. S. Bx.)

MAHAVAMSA: see PALI LITERATURE.

MAHAVIRA, VARDHAMANA JNATRIPUTRA (6th century B.C.), a contemporary of Buddha, was the 24th and last *tirthankara* ("prophet") of the Jains and the founder of the present form of their creed. Mahavira is an honorary title meaning "great hero." According to Jain tradition, his dates were 599-527 B.C., but the two Jain sects, Shvetambaras and Digambaras differ in their accounts of his life, which is confused with many legends. The historical facts are that he was born in Vaishali, the younger son of a king named Siddhartha and of his wife Trishala. He married a noble lady by whom he had a daughter, but at about the age of 30 he renounced the world and for 12 years led a life of self-mortification as a wandering beggar, even discarding his clothes. At the end of this period he reached the state of omniscience, and for the rest of his life he taught his doctrines to his ascetic disciples and to an ever-increasing number of laymen. Although he was of a reserved nature, his personality seems to have left a deep impression.

Mahavira's teaching was a systemization of that of Parshvana-
tha, the 23rd *tirthankara*, who is said to have lived about 250
years earlier. Recensions of some of Mahavira's discourses are
extant in the sacred books of the Jains, written in Prakrit dialects,
their final redaction dating probably from the 5th century A.D.
It is uncertain how far any of the sayings there attributed to him
are genuine: the Shvetambaras acknowledge their authenticity
but the Digambaras deny it. As, however, the doctrines of the two
sects differ only in matters of minor importance and bear the stamp
of a very archaic mode of thinking, it seems not improbable that
their leading ideas may go back to his teaching. See also JAINISM.

MAHAWELI GANGA (Sinhalese for "Great Sandy river"),
the longest river in Ceylon. It has a complicated and tortuous
course. Rising on the westward side of the north-south axis of
the highland which bisects the hills of Ceylon, and flowing north-
west, it drains an important tea-growing area. The river then
changes course, flowing east of north through the villages and
estates round Kandy, whence it turns east and plunges down
through a mighty valley which cuts through the north-south axis
and receives the drainage of the Uva basin. The Mahaweli, joined
by its main tributary the Amban Ganga (left), then flows north
through the lowland dry zone, in largely undeveloped territory,
till it reaches its deltaic lowlands on the east coast, and discharges
into Koddidiyar bay south of Trincomalee. These lowlands have a
large area of paddy fields which, with others along the river's dry
zone course, benefit from the fact that, unlike most dry zone rivers,
it is perennial by reason of its wet zone headwaters and tributaries.
See also CEYLON: *Physical Geography*. (B. H. F.)

MAHAYANA (GREAT VEHICLE) is one of the two major
schools of Buddhism, the other being Theravada. As a "vehicle,"
i.e., conveyance, it is "great" because it teaches, by its cardinal
doctrine, the broad path to salvation: all sentient beings possess
the Buddha-nature and hence are capable of attaining enlighten-
ment. The Mahayana aspect of Buddhism, which is followed in
Tibet, China and Japan, probably developed during the two cen-
turies before the Christian era, with its starting point very likely
furnished by the speculations on the nature of the Buddha devel-
oped by the Mahasanghikas, a group of dissident monks who broke
away from the orthodox community at the second great Buddhist
council c. 383 B.C. According to this school, the Buddha was no
longer a human teacher but a *lokottara* or supramundane being
who appeared on earth in an apparitional form as Sakyamuni (see
GAUTAMA BUDDHA).

The Mahayana stresses the importance of faith and devotion
to the Buddha and the Bodhisattvas (see BODHISATTVA), and love
for all creatures, manifested by compassion and charity. Accord-
ing to the Lotus (Saddharma Pundarika) Sutra, one of the im-
portant Mahayana scriptures, anyone who hears the Master's
teachings, who worships an image or relic of the Buddha or who
makes a statue even of sand will attain enlightenment; according
to the Pure Land (Sukhavativyūha) Sutra, it is necessary only to
utter the name of the Buddha Amitabha (*q.v.*) in loving adoration.
The Mahayana scriptures were composed mainly in Sanskrit and
survive largely in Tibetan and Chinese translations.
For a study of Mahayana Buddhism as it is practised in the
modern world, it is necessary to go to Japan. See JAPAN: *The*
People: Religion; BUDDHISM. (K. K. S. C.; X.)

MAHBUBNAGAR, a town and district of Andhra Pradesh,
India. The town, formerly called Palmur and headquarters of the
district, lies 55 mi. S.W. of Hyderabad on the Secunderabad-
Bhadrachalam metre-gauge line of the Central railway. Pop. (1961) 35-
583. There are several cotton-ginning and -pressing factories, a
college, an American Baptist Mission high school and the district
jail.
MAHBUBNAGAR DISTRICT has an area of 7,119 sq.mi. and a pop.
(1961) of 1,590,686. It is occupied by Archean gneiss except
along the banks of the Krishna (Kistna) river, where the rocks
belong to the Cuddapah and Kurnool series. It is held that the

famous Golconda diamonds were obtained from these rocks. The
district also contains large tracts of forests. The average annual
rainfall is 34 in. The staple food crops are jowar (sorghum),
bajra (millet), rice and oilseeds. Coarse cotton cloth is woven.

Narayanpet, a trading town in the west, is well known for manu-
facture of superior silk and cotton saris and coloured leather
slippers which are largely exported. Coarse rugs and blankets are
woven in Makhtal, Devarkonda, Nagarkurnool and Amrabad.
There is a hill fort at Pangal with a perennial spring of sparkling
water. The fort of Koilkonda, 14 mi. S.W. of the town, stands
on an 800-ft. hill and was constructed in the 19th century by
Ibrahim Kutb Shah, one of the Golconda kings. Mananore is a
hilly place set amid a scenic landscape. On a hill nearby is a state
prison for political prisoners. (S. AH.)

MAHDI (AL-MAHDI, Arabic, literally "the [divinely] guided
one"), a figure in Islamic eschatology. The Koran does not men-
tion him, and almost no *hadith* or saying attributed to the Prophet
Mohammed concerning the Mahdi can be adduced which is free
of the suspicion of being a later fabrication. Mahdist beliefs have
accordingly been questioned by many orthodox Sunni Muslim theo-
logians, though such beliefs form a necessary part of doctrine for
the sects of the Shi'a, or "faction," of 'Ali (the Prophet's cousin
and son-in-law; see SHI'ISM).

Regardless of the opinions of the theologians, the Muslim masses
have long believed in and hoped for a messianic deliverer who as
the Mahdi will fill the earth with justice and equity "even as it
is now filled with oppression," restore true religion and usher in
a short golden age lasting seven, eight or nine years, before the
end of the world. Other accounts add that he will slay *al-Dajjal*,
the Deceiver, or assist Christ to slay him. According to some ac-
counts, the Mahdi will be Jesus ('Isa in the Koran), the son of
Mary, who will descend to earth, rule according to the Islamic law
and confound both the Jews who would not recognize his prophet-
hood and the Christians who blasphemously worshiped him.

Other accounts state that he will be a descendant of the Prophet,
and such a descendant, variously identified, is awaited by the
Shi'a. The "Twelver" Shi'a of Iran hold that he will be their 12th
imam, Mohammed ibn al-Hasan al-Askari.

The doctrine of the Mahdi seems to have gained currency dur-
ing the confusion and insecurity of the religio-political upheavals
of early Islam, in the 7th and 8th centuries A.D. Probably the
first attempt to make use of the doctrine occurred in year 66 of
the Hegira (A.D. 686) when one Mukhtar ibn Abi 'Ubayd put for-
ward the claim to allegiance of Mohammed ibn al-Hanafiyya, a
son of 'Ali by a wife other than Fatima, daughter of the Prophet.
As the two sons of Fatima and 'Ali had died, leaving no mature
heirs, many pro-'Alids were at this time disposed to follow this
Mohammed, though he himself refused to lead their faction.
When he died, Mukhtar taught that his Mahdi remained alive in
his tomb on Mt. Radwa in a state of occultation (*ghayba*), and
would reappear to vanquish their enemies. It seems clear that
Mukhtar borrowed the idea from the Jews or the Christians, or
both, who were expecting a first or second coming of the Messiah.
Following this, other Shi'a sects preached other Mahdis. The
Abbasid revolution of 132 A.H. (A.D. 750) made use of eschatologi-
cal prophecies current at the time that the Mahdi would rise in
Khurasan in the east, carrying a black banner.

As a repository of hopes, belief in the Mahdi has tended to
receive new emphasis in every time of crisis. Thus after the bat-
tle of Las Navas de Tolosa (A.D. 1212) when most of Spain was
lost for Islam, Spanish Muslims circulated traditions ascribed to
the Prophet foretelling a reconquest of Spain by the Mahdi. Dur-
ing the Napoleonic invasion of Egypt, a person claiming to be the
Mahdi briefly appeared in Lower Egypt.

Because the Mahdi is seen as a restorer of the political power
and religious purity of Islam, the title has tended to be claimed
by social revolutionaries in Islamic society, who desired thus to
acquire power against an existing government. North Africa in
particular has seen a number of self-styled Mahdis. Among the
most important of these are the Mahdi 'Ubaydullah, who in 297
A.H./A.D. 909 assumed power in Tunisia as first ruler of the im-
portant Fatimid caliphate (see FATIMIDS), from which the Aga

Khan claims descent; the Mahdi Mohammed ibn Tumart, founder of the Almohad movement in Morocco in the 12th century (see *ALMOHADS*; *IBN TUMART*); and Mohammed Ahmed, the Mahdi of Sudan, who in 1881 raised a revolt against the Egyptian administration and defeated before his death in 1885 several mixed British and Egyptian forces sent against him, thus becoming a forerunner of Sudanese nationalism (see *MOHAMMED AHMED*).

The title has also naturally been a chosen instrument for founding new religious movements. In India, Mirza Ghulam Ahmad of Qadiyan in the late 19th century announced that he was Christ and the Mahdi, and founded the Ahmadiya sect of Muslims so active in missionary enterprises (see *ISLAM: Sects: Ahmadiya*). The Baha'is trace their origins to the activities of Mirza 'Ali Mohammed of Shiraz, in Iran, who around 1844 put forward his claim to be Mahdi; but his writings also speak of one "whom God shall make manifest," to come after him: this is Baha'ullah in the Baha'i system. (See *BAB*; *BAHA'I FAITH*; *BAHA'ULLAH*.)

It may be seen then that Mahdism has formed an important element of folk-Islam for the masses, even though it is not a part of official Sunni Islam. Among the Shi'a schools, disagreement on the identification of the Mahdi has been one of the chief factors separating sect from sect.

Finally, Muslim rulers have often sought to appropriate something of the *charisma* of the name by taking it for themselves; e.g., the caliph al-Mahdi, father of Harun al-Rashid the Abbasid.

MAHDIA, a north African fishing port on the Sahel (coastal strip) in Sousse governorate, eastern Tunisia. It lies on the narrow rocky peninsula of Ras Mahdia or Cape Africa (Africa being the name by which Mahdia was known to historians in the middle ages) and is 42 mi. S.E. of Sousse town by road. Pop. (1956) 10,842. The seaward end of the peninsula contains only ruins and cemeteries, being dominated by a 16th-century Turkish fort. The oldest quarter surrounding the large 10th-century mosque is becoming derelict. The town is developing more to the west beyond a monumental gate (part of the remains of the ancient wall), toward the neighbouring villages and southwest toward the port. Many of the inhabitants own olive groves and gardens in the hinterland; the larger proprietors have oil mills and there is an oil-cake factory. Traditional handicrafts include wool and silk weaving, embroidery and the manufacture of fine garments. During the summer months nocturnal fishing with the use of lanterns to attract the shoals (sardines, mackerel) occupies hundreds of families; the town has several fish canneries. All communication is by road, as the small port is used only by the fishing craft.

Mahdia, probably on the site of the ancient Gummi, owes its name to the mahdi (Arab, "the [divinely] guided one"), 'Ubaydullah, founder of the dynasty of the Fatimids (q.v.). He established the town in A.D. 912 and in 921 made it his capital, but it was abandoned in favour of Kairouan by the caliph al-Mansur in 947. For a short period at the end of the 11th century it was the refuge capital of the Zirid dynasty and from 1148 to 1160 it was occupied by the Normans of Sicily. Thereafter, although for a time the base of the 16th-century Turkish corsair Dragut, Mahdia was no more than a small town and the principal place of the southern Sahel.

Mahdia was created a *commune* in 1887 and is the headquarters of a *délégation* (administrative district) for the cheikhat (sheikhdoms) of Ayaicha, Chiba, El-Mendra, Houmt-es-Souk, Mahdia-Ville, Mahdia-Banlieue, Rejiche and Sidi-Said. (J.-J. Ds.)

MAHE, on the Malabar coast of India, a territory of Pondicherry and formerly a French settlement, lies 35 mi. N.W. of Kozhikode and 451 mi. S.W. of Madras. Pop. (1960 est.) 18,298. Area 23 sq.mi. The territory, an enclave in the Cannanore district of Kerala, consists of two parts: the quaint picturesque town of Mahé with all its buildings situated on the left bank of the Mahé river close to its mouth; and the isolated tract known as Naluthara on the right bank, comprising the four villages of Chambara, Chalakara, Palour and Pandaquel. Rice is the chief crop.

The French under Bertrand François LaBourdonnais, comte de Mahé (whence its name), captured the town in 1726, and in 1731 they acquired Mt. d'Eli (mountain of rats) and a few outposts in the north, all of which fell to the English in 1761. Mahé was taken by the English three times, but was eventually restored to the French in 1817. *De facto* transfer of the former French possessions to the Union of India took place on Nov. 1, 1954, and *de jure* transfer in May 1956. Now it is directly administered by the government of India through a chief commissioner at Pondicherry. (G. Kn.)

MAHER PASHA, ALI (1882–1960), Egyptian statesman and prime minister. Born in Cairo, of which his father was a one-time governor, in 1882, Ali Maher took a law degree in 1902 and, after three years practice, became a judge in the native court. In 1923 he was appointed director of the Royal Law school and played an important part in drawing up the Egyptian constitution of that year.

He soon returned to politics. In various administrations he was minister of education and minister of finance. A professed constitutionalist, he was inclined to authoritarianism and was the first to be chosen by King Fuad, in 1935, for the new role of chief of the royal cabinet. At the end of 1935 he became prime minister in a caretaker government. During the next two years (1936–37) he served King Faruk first as prime minister and later as chief of the royal cabinet. He became prime minister again in 1939 and on the outbreak of war took the measures required by the Anglo-Egyptian treaty. But he remained friendly toward the Italians and when Italy declared war in 1940 he was replaced, at British insistence. In April 1942 he was interned and remained in custody until the end of the war. In Jan. 1952 he formed a ministry in succession to that of Nahas Pasha, but this government lasted no more than two months. On July 24, 1952, one day after the military revolution, Ali Maher formed, at the request of the officers, a government largely composed of independents, but he soon fell from power and retired from politics within a year. He died at Geneva on Aug. 25, 1960. See also *EGYPT: History*. (H. S. D.)

MAHESHWAR, a town in the Nimar West district of the Indore division of Madhya Pradesh, India, 60 mi. S. of Indore. Pop. (1961) 8,089. It lies on the north bank of the Narmada river at the site of ancient Maheshwari, mentioned in the epics, *Ramayana* and *Mahabharata*, known as the capital of Haihaya king Sahasrarjun, who, according to the *Puranas*, lived about 2000 B.C. Broad ghats on the river sweep upward toward the fort and temples, behind which towers the lofty palace of Ahalya Bai, the famous Holkar queen, who in 1767 selected Maheshwar as her capital.

Facing Maheshwar on the opposite bank of the Narmada is Navdatoli, where excavations have revealed traces of an early settlement containing, besides other relics, pieces of painted pottery and unique channel-spouted cups. See *INDIA-PAKISTAN, SUB-CONTINENT OF: Archaeology*.

See H. D. Sankalia, B. Subbarao and S. B. Deo, *Excavations at Maheshwar and Navdatoli, 1952–53* (1959). (S. M. A.)

MAHI, a river of western India, rising in southwestern Madhya Pradesh and flowing through southern Rajasthan and Gujarat states, enters the sea by a wide estuary past the old port of Cambay. The silt brought down by this river, together with that of the Narmada and Tapi to the south, has contributed to the silting of the Gulf of Cambay and the abandonment of its once prosperous ports. The total length of the Mahi is 350 mi. and its estimated drainage area 17,000 sq.mi. (L. D. S.)

MAHICAN AND MOHEGAN, cognate Algonkian tribes (q.v.) that respectively inhabited the upper Hudson valley above the Catskills in New York and the Thames valley in Connecticut. Both names refer to "wolf," with many variants, as in James Fenimore Cooper's *The Last of the Mohicans* (mistitled: mixed-blood descendants of both tribes survived in the 1960s near Norwich, Conn., Stockbridge, Mass., and at Oneida, Wis.). The Mahican became known as River Indians to the Dutch and English; their importance in the fur trade faded with the rise of the Mohawk (q.v.). Originally one with the Pequot tribe under Chief Sassacus.

the Mohegan became independent in 1637 under the rebel subchief Uncas, who enjoyed English favour for a time. Surviving King Philip's War (see PHILIP, King), the Mohegan settled near New London, Conn.

MAHILLON, VICTOR CHARLES (1841-1924), Belgian musical scholar and authority on wind instruments. The son of Charles Mahillon (1813-87), the founder of a firm of wind-instrument makers, he was born in Brussels, March 10, 1841, and entered his father's business (1865). As curator of the museum of the Brussels Conservatoire, he formed a collection of over 1,500 instruments of which he published an analytical catalogue (1880-1922), containing demonstrations of the theories of instrument construction and a methodical classification of ancient and modern instruments. He had copies made of rare instruments, and adapted some of them, notably the Bach trumpet, for modern use.

Mahillon published *Les Éléments d'acoustique musicale et instrumentale* (1874), and numerous monographs on instruments and organized concerts of historical works played on old instruments.

Mahillon died at St. Jean, near Cap-Ferrat, June 17, 1924.

See E. Closson, *La Facture des instruments de musique en Belgique* (1935).

MAH-JONGG, a western version of a Chinese game, is played with 136 or 144 tiles or *p'ais*, similar to dominoes but engraved with Chinese symbols and characters and divided into suits and honours. A fad in England, the United States and Australia in the mid-1920s, the game was revived in the U.S. after 1935 but never regained its initial popularity. The game that came to be known as mah-jongg is probably of 19th-century origin. Before World War I, each Chinese province had its own style of play and dialect name for it. Signifying "sparrow" or hemplike bird, the name has been variously transliterated as *ma tsiang*, *ma chiang*, *ma cheuk* and *ma ch'iau*. The sparrow or a mythical "bird of 100 intelligences" appears on one of the tiles. The name mah-jongg was coined and copyrighted by Joseph P. Babcock, a U.S. resident of Shanghai who is credited with introducing mah-jongg to the west after World War I. He wrote a modified set of rules, gave English titles to the tiles and added index letters and numerals familiar to western card players.

Pieces.—Modern mah-jongg sets are usually made of plastics instead of bone or ivory. A full mah-jongg set contains 136 or 144 tiles depending on whether the flowers or seasons are used. Some sets include 20 flowers. The pieces are named and numbered as follows:

1. Bamboos, numbered 1 to 9, four of each number.....36 tiles
2. Circles, numbered 1 to 9, four of each number.....36 tiles
3. Characters, numbered 1 to 9, four of each number.....36 tiles
4. Honours, 4 red dragons, 4 green, 4 white dragons.....12 tiles
5. Winds, 4 east winds, 4 south winds, 4 west winds,
4 north winds.....16 tiles

136 tiles

In addition:

6. Flowers and seasons, 4 of each or 8 of either.....8 tiles

144 tiles

The bamboos are often called sticks or bams, the circles dots, the characters cracks or craks. The set also includes two dice, a quantity of tokens or plastic chips used for scorekeeping and a rack for each player whereon he can place 14 tiles with their faces visible only to himself.

The Game.—The usual game is for four, each playing for himself (there are no partners). The object of play, similar to that of the rummy card games, is to obtain sets of tiles. There are three kinds of sets: (1) "chow," a run or sequence of three tiles of the same suit in numerical order; (2) "pung," a sequence of three like tiles of the same suit and rank, three dragons of the same colour or three identical winds; and (3) "kong," a pung plus the fourth matching tile. The winner is the first player to hold a complete hand; i.e., four sets and a pair of like tiles (14 tiles). The strategy of mah-jongg, like that of rummy, is both offensive

and defensive: to complete a "woo" or winning hand as quickly as possible; to block other players by not discarding tiles useful to them; and to build a high-scoring hand. Beginning with "east wind" (who collects or pays double according to whether he or another player wins), each player draws his "hand" and places it in his tile rack, east taking a total of 14 tiles and the others 13. The flowers or seasons are not counted as part of a 13-tile hand; on drawing such a tile, the player immediately "grounds" it face up and draws another tile. East begins the play by discarding one tile, reducing his hand to 13. Thereafter, the other players, in counterclockwise rotation, each draw one tile, which may be the last discarded tile or a loose tile from the "wall" (comparable to stock in rummy). Any player, regardless of whether it is his turn, may claim the previous discard if it completes his set. (If two or more players claim the same discard, there is a detailed order of precedence.) The losing players settle with the winner and with each other according to the accepted schedule of values for the sets or combinations of sets. A concealed set held in the hand scores differently from an exposed set on the table.

Under certain rules, exceptionally complete hands or "limit hands," picturesquely named "the three scholars," "four small blessings," etc., are scored differently. In U.S. play the emphasis on limit hands eventually far exceeded that under Chinese rules until high scores were accented over playing skill. A certain

school of players restricted the winning hand to a very narrow list and made the flowers wild. Various other innovations followed. One was the "clear-handed" rule: woo hand may contain only tiles of one suit plus honours. The conflict led to publication of *Laws of Mah-Jongg* (1925) by Babcock and others, giving an option between the Chinese game and the clear-handed variant. Shortly after, the Mah-Jongg fad collapsed.

In 1937 Viola Cecil organized the National Mah Jongg league in the U.S. to standardize a new version of the game. Its innovations included the "Charleston," or exchange of tiles between players before the start of play, and the use of 22 flower tiles (wild or jokers except in certain winning hands).

MAHLER, GUSTAV (1860–1911), Austrian composer and conductor, was born at Kalischt (Kaliste), July 7, 1860, the son of a poor Jewish innkeeper in a Bohemian outpost of the Austrian empire. He studied at the Vienna conservatory, winning piano and composition prizes, and became a provincial opera conductor to earn a living, rising through important posts in Budapest (1888–91) and Hamburg (1891–97) to the position of artistic director at the Vienna opera (1897). For ten years through his will and energy he achieved a superlative standard of performance. During the summer vacations of this period he also tirelessly pursued his work as a composer. In 1907 his unpopularity as a taskmaster, fomented by anti-Semitism, compelled his resignation. He then spent three seasons conducting the New York Philharmonic orchestra and the Metropolitan opera, returning to Austria each summer to compose. He died in Vienna, May 18, 1911.

Mahler's compact mature output consists entirely of symphonies and songs. Most of the 40 songs are not true *Lieder* but rather are embryonic symphonic movements; their character, and sometimes their materials, provide the stylistic basis of the ten symphonies. Song and symphony, together with *Das Lied von der Erde* ("The Song of the Earth"), which fuses the two genres, make up a continuous, consistent *oeuvre*, a spiritual autobiography. Mahler inherited the romantic conception of music as an expression of a quest for spiritual reality; and partly because of his unhappy childhood and his Jewish sense of exile, he expressed a four-sided conflict between a devouring love of life, a spiritual need, a skeptical intellect and an existentialist dread of ultimate meaninglessness. He drew together many different strands of romanticism: Beethoven's conflict symphony; Liszt's and Tchaikovsky's program symphony; Wagner's and Bruckner's enlarged time scale, expanded orchestra, prominent brass tone and emotional intensity; Bruckner's and Schubert's Austrian folk style. Yet his vivid musical personality and orchestral imagination allowed him to remain entirely himself, though he drew on elements from many composers and on the realistic effects of bird song, military signals and marches, country dances (the *Ländler*), and café music (the Viennese waltz). These latter features, original stylizations very like the real things and often used in the manner of collage in painting, give a peculiar dimension to Mahler's art, a Hoffmannesque irony that challenges the prevalent romantic idealism. Thus each symphony becomes a struggle to create idealistic values in face of intractable reality.

Of Mahler's three periods, the first comprises the folklike songs "Des Knaben Wunderhorn" and "Lieder eines fahrenden Gesellen," and the symphonies 1–4, the last three of which use voices and have mystical associations. Then follows the sterner, more realistic trilogy of purely orchestral symphonies 5–7, together with the haunting songs on poems of Friedrich Rückert (which include the "Kindertotenlieder"). The gigantic, fully choral Eighth Symphony stands alone, the real third period comprising *Das Lied von der Erde*, the Ninth Symphony, and the unfinished Tenth (available in a performing version by Deryck Cooke since 1964). In these dark works, written under the shadow of death, certain tendencies in Mahler's music come to a head—dissolution of tonality, spare dissonant counterpoint, continuous variation and chamber orchestration; they exerted a considerable influence on Arnold

Schoenberg, Alban Berg, Anton Webern, Dimitri Shostakovich and Benjamin Britten.

MAHMUD I (1696–1754), Ottoman sultan of Turkey, the elder son of Mustafa II, was born at Edirne (Adrianople) on Aug. 2, 1696. A mob rising led by Patrona Khalil deposed his uncle Sultan Ahmed III and put Mahmud on the throne on Oct. 1, 1730. Although he had lived in seclusion all his life and had had no training in administration, he succeeded in restoring order. Patrona Khalil was assassinated at the meeting of the divan (the council of state) on Nov. 15, 1730, and a military mutiny was suppressed in 1731. A war with Persia that lasted, with intervals, until 1746 was unsuccessful, but Russia and Austria were forced in 1739 to sign a peace treaty at Belgrade on terms favourable to Turkey. Russian designs on the Crimea and Moldavia, and Austrian designs on the Danubian principalities received a check.

Following the wise advice of the Comte de Bonneval (Ahmed Pasha), a French convert to Islam, Mahmud took an active interest in political and military affairs. He maintained friendly relations with France, Great Britain and Sweden and attempted a partial westernization of the Turkish army. He died of heart disease at Istanbul on Dec. 13, 1754. A patron of music and literature, he himself wrote poetry in Arabic. See also *TURKEY: History*. (E. Z. K.)

MAHMUD II (1785–1839), Ottoman sultan of Turkey, son of Abdul-Hamid I, was born on July 20, 1785, and succeeded his brother Mustafa IV on July 28, 1808. Influenced by the reforming zeal of a former sultan, Selim III, he devoted himself during his reign to solving the internal and external problems of his country. In 1808 the janizaries revolted against him and his grand vizier, Bairaktar, who was carrying out reforms. Mahmud allowed them to kill Bairaktar and he strangled his own brother Mustafa, the former sultan, who was the only prospective heir to the throne. In 1812 the war with Russia, which had continued fitfully after a truce in 1807, was ended by the treaty of Bucharest. Three years later, Mahmud had to recognize the virtual autonomy of Serbia.

These events were followed by the revolt of Ali Pasha in Albania (1820–22) and by the rising of the Greeks in the Morea (1821–27). Being unable to crush the Greek rebellion, Mahmud was compelled to summon to his assistance the pasha of Egypt, Mohammed Ali, whom he had already employed to suppress the Wahhabi rebellion in Arabia. The Egyptian army had partially restored the authority of Mahmud in the Morea by 1826, but the united British, French and Russian fleets destroyed the Turkish and Egyptian fleets in the Bay of Navarino (Oct. 10, 1827). After vainly attempting to obtain an apology and reparation for "this revolting outrage" Mahmud proclaimed a holy war against the infidels. This resulted in the Russo-Turkish war of 1828–29, the defeat of the Turkish army and the conclusion of the peace of Adrianople (1829).

In 1831 a new crisis arose. Mohammed Ali Pasha, already governor of Egypt and Crete, demanded the pashaliks of Syria and Tarsus which had been promised him as a reward for his help against the Greeks. When Mahmud refused this demand, Mohammed Ali sent an army into Syria. During the next two years, this army, under the command of Ibrahim Pasha, conquered southern Palestine and captured Acre and Damascus. It routed the main Turkish army at Konya (1832) and advanced toward the Bosphorus. To save his throne Mahmud was forced to seek foreign aid. France, which had taken Algeria in 1830, favoured Mohammed Ali. Great Britain was unwilling to intervene alone. Only Russia, the hereditary enemy of Turkey, offered help. This Mahmud accepted with the words "a drowning man clings to a serpent." The Russian expedition to the Bosphorus, the convention of Kütahya and the treaty of Unkiar Skelessi followed (1833). By the convention of Kütahya, Mahmud agreed to appoint Mohammed Ali as governor

of Syria and Tarsus and his son Ibrahim as governor of Adana, but Mahmud was determined on revenge. In April 1839 a Turkish army invaded Syria, but it was defeated by the Egyptian army at Nizip on June 24. Mahmud died at Constantinople on July 1 without hearing the news.

Although Mahmud was unfortunate in his wars and foreign policy his efforts as a reformer were successful. The inefficiency of the janizaries during the Greek rising convinced him of the inherent superiority of European methods. In 1826 he destroyed the janizaries, who had risen in revolt, and set to work to establish a national army with the help of German instructors. A military academy was established. Other reforms included the introduction of compulsory primary education; the opening of a medical school; a census of the population of Anatolia and European Turkey; and the exchange of oriental for European dress. Students were sent to Europe. He abolished the sultan's right to confiscate the property of deceased officials; adopted the cabinet system of government; and established permanent embassies in the European capitals. Before his death, he attempted to introduce political equality, declaring that Muslims, Christians and Jews all had the same rights under his fatherly protection. During his reign Mahmud lost territories, but when he died he left his empire stronger than he found it. He was a great reformer who did much to introduce western civilization into Turkey.

MAHMUD OF GHAZNI (971-1030), Turkish creator of a Ghaznavid empire stretching, at the end of his reign, from Ray and Isfahan in Iran to Lahore in India, from the Oxus (Amu-Darya) river to the coasts of Makran; plunderer of Hindustan, legendary hero of Islam in India. The eldest son of Subuktigin (q.v.), Mahmud took part as a youth in campaigns against the hill chieftains of Ghor (q.v.) and against the Hindu-Shahi ruler Jaipal and assisted his father in Khurasan in his struggles against rival Turkish officers of the Samanid kingdom of Samarkand and Bukhara. In 994, the Samanid Amir Nuh appointed Mahmud to command his troops in Khurasan with the title of Saif ud-Daula ("sword of government").

On the death of his father in 997, Mahmud did not acquiesce in Subuktigin's nomination of a younger brother, Ismail, as his successor at Balkh and Ghazni (q.v.), but defeated him outside Ghazni and imprisoned him.

Although Mahmud is famous for his campaigns in Hindustan, his main political achievement, short-lived though it proved to be, was the creation of a Ghaznavid empire in eastern Iran and Afghanistan. Until 999 Mahmud, like his father, acknowledged the overlordship of the Samanids, but in that year the Qarakhanid Lak Khan took Bukhara and captured and exiled the remaining members of the Samanid family. Before this extinction of his nominal suzerains Mahmud had, however, effectually excluded the Samanid forces from Khurasan. His assumption of an independent rule clearly dates from this year, the year when the caliph, al-Kadir, conferred upon him the title of *Yamin ud-daula wa Amin ud-Milla* ("right hand of government and guardian of the community").

Master of the chief cities of Khurasan, Mahmud had to defend himself against the Qarakhanid empire centred in Turkistan east of the Jaxartes (Syr-Darya) river. In 1005-06, returning rapidly from an expedition against Multan in Sind, he repulsed an attempt by the Ilak Khan to conquer Khurasan. He was obliged to repeat his success in Jan. 1008, defeating the Qarakhanid forces on the plain of Katar near Balkh. Under the Ilak Khan's successors friendly relations with the Qarakhanids were generally maintained.

In 1025, however, Mahmud intervened in Transoxiana with a large army which made the crossing of the Amu-Darya on a bridge of boats. In April 1025 he ceremoniously met Qadir Khan of Kashgar, "the chief of all Turkistan," and concluded an alliance with him. A wary *modus vivendi* between the two great powers, founded on the maintenance of Transoxiana as a buffer region between them, lasted until Mahmud's death in 1030.

Elsewhere, Mahmud annexed Gharjistan, in the area of the upper Murghab, in 1012, and in 1017 asserted his suzerainty over

Khwarizm. To the south and west of Ghazni he annexed Seistan (1002-03), subdued the chiefs of Ghor (1009 and 1020) and in 1011-12 asserted his overlordship over Qusdar, the northeastern half of modern Baluchistan. In the farther west, in 1029, he conquered the Buyid principality of Ray. The last years of his reign, however, were darkened by the threat of the Seljuks (q.v.). Mahmud was able to control them in his lifetime, but within ten years of his death they had swept away the power of his son Mas'ud in Khurasan.

Mahmud's Indian campaigns opened in 1000 with the capture of some fortified places around Lamaghan. In 1001 he defeated Jaipal, the raja of Waihind, near Peshawar, capturing him and concluding a peace with booty. Further defeats of the Hindu-Shahis followed in 1006 and in 1008-09 when Nagarkot (Kangra) was plundered. Earlier, in 1004 Mahmud had taken the fort of Bhatinda, in 1006 the Ismaili stronghold of Multan. In 1014 he captured Thanesar. The way was now open for the penetration of the Ganges-Jumna doab; in 1018 Multa was sacked; in this and the following year, Mahmud swooped down the Ganges to Kannauj and Kalinjar whose rajas had formed a temporary league against him. In 1022-23 Ganda of Kalinjar was reduced to a tributary. In 1025, Mahmud embarked upon his most famous Indian exploit, the crossing of the desert from Multan to Somnath on the Kathiawar peninsula to sack the city and temple there. His only permanent territorial acquisition in India was the Punjab (1021) but its incorporation in the Ghaznavid kingdom was to make Hindu India vulnerable to future Muslim incursions.

Following the precedents and traditions of the Samanid polity, the Ghaznavid empire under Mahmud was founded on a broad functional division of power between a predominantly (though not exclusively) Turkish military élite, often of slave origin and promoted, after service in the royal household, to army commands and provincial governorships, and a bureaucratic hierarchy, staffed mainly by Persians, responsible for collecting revenue.

Mahmud's reign coincided with a remarkable flowering of Perso-Islamic literature, which revived and sought to make Mahmud the focus of many of the traditions of pre-Muslim Iran. At his court were to be found the poets Firdausi, Unsuri and Asadi and the scholar al-Biruni. He became the hero of many legends and anecdotes, particularly centring around his relationship with his favourite slave Ayaz. As plunderer of Hindu temples and destroyer of idols, and as a persecutor of the Karmatians, posthumously Mahmud enjoyed a great reputation as a warrior for the faith and an archetype of the pious Muslim ruler in an age when the Sunni caliphate had visibly failed to fulfill Islamic ideals. Indeed, it may be said that, for all his courage, energy, military skill and self-reliance, Mahmud's role in Muslim historiography and "political" theory as this archetype outweighed and outlasted his actual achievement in Muslim history. MAHMUD NEDIM PASHA (c. 1818-1883), Ottoman grand vizier of Turkey, was the son of Nejib Pasha, formerly governor general of Baghdad. He was successively undersecretary of state for foreign affairs; governor general of Syria and Smyrna (Izmir); minister of commerce; governor general of Tripoli; minister successively of justice and marine (1869); grand vizier during 1871-72 and 1875-76; minister of the interior during 1879-83.

His policy and administration were reactionary. He allowed Sultan Abdul-Aziz to become an absolute monarch, thus destroying the liberal influence that previous ministers had taken over 30 years to introduce from Europe. As grand vizier, Mahmud Nedim tried to keep his office by flattering the sultan and by providing him with money for his extravagance. In foreign policy, owing to his enmity toward liberal ideas, he opposed Britain and France and won the friendship of Russia. By 1875 he was basing all his decisions on the advice of Count Nicholas Ignatiev, the Russian

ambassador in Constantinople, a fact which earned him the nickname of "Mahmudov." In 1876, after the rising in Bulgaria occasioned by Ignatiev's intrigues, Mahmud Nedim became so unpopular that threats were made to assassinate him. To calm public feeling Abdul-Aziz dismissed him. Mahmud died in Istanbul on May 14, 1883. (E. Z. K.)

MAHOGANY is among the foremost cabinetwoods of the world and one of the most valuable timbers in tropical America. It is the product of the genus *Swietenia*, family Meliaceae. Other hardwoods are called mahogany because of a resemblance in colour or texture to the wood of *Swietenia*.

True Mahogany.—The species first discovered was the West Indies mahogany (*Swietenia mahagoni*), native in the Bahamas, Cuba, Jamaica, Hispaniola and southern Florida. More important commercially is Honduras mahogany (*Swietenia macrophylla*) of southern Mexico, Central America and South America, found in Colombia, Venezuela and the upper Amazonian region of Peru, Bolivia and western Brazil.

Mahogany trees are scattered through wet tropical forests and are grown in plantations and for shade and ornament around the world. The alternate pinnate leaves have 4 to 12 paired, shiny, pointed leaflets with the two sides unequal. Many small greenish-yellow five-petaled flowers are borne in clusters. The distinctive hard, pear-shaped seed capsules split into five parts from the base upward, releasing many winged seeds. The wood characteristically is rich reddish brown, especially after exposure, though when freshly cut it ranges from light pink to golden brown. It is fine-textured with scattered pores and often with a highly attractive figure, such as a stripe, mottle, fiddleback or swirl. Of uniformly high grade, it is easily worked, takes a beautiful polish, stains and glues readily and is strong and durable.

The oldest surviving use of carved mahogany is in the cathedral at Santo Domingo, built 1514-40. Hernán Cortés in 1521 adapted it for shipbuilding. One of the first recorded uses in England was at Nottingham castle in 1680. For fine furniture, mahogany became popular in the early part of the 18th century, when cabinet-makers began to carve decorations on this strong wood. Other uses include cabinetwork, television cabinets, paneling, veneers, plywood, molded plywood boat hulls, yacht interiors, working models and foundry patterns. In World War II mahogany served for PT boats and aircraft.

Other Mahoganies.—The word mahogany, usually with a descriptive or geographic qualification, has been applied to nearly 200 other species. Khaya, or African mahogany, is obtained from the genus *Khaya* (mostly *Khaya ivorensis*; family Meliaceae) in West Africa, mainly Ivory Coast, Ghana and Nigeria. Wood of related genera, for example sapele (*Entandrophragma cylindricum*), also has been marketed as African mahogany. The trade name Philippine mahogany has been applied to red lauans (*Shorea negrosensis*, *S. polysperma*—also called tangle—and related species) from the Philippine Islands; they belong to the dipterocarp family (Dipterocarpaceae). The U.S. Federal Trade commission has approved the names African and Philippine mahogany but otherwise restricts mahogany to woods of *Swietenia*.

In western North America several species of shrubs and small trees of the genus *Cercocarpus*, of the rose family, with hard, fine-grained, reddish wood, are known as mountain-mahogany. Lemonade sumac (*Rhus integrifolia*), a handsome evergreen shrub or small tree of southern California and Mexico, has been called mahogany sumac or mahogany. (E. L. L.)

MAHÓN (PORT MAHÓN), a town of Spain, capital of Minorca, in the Balearic Islands. Pop. (1960) 16,619. Located on the southeast side of the island, Mahón has a natural harbour, one of the finest in the Mediterranean, extending inland 3½ mi. Because of its harbour Mahón replaced Ciudadelà as capital of Minorca during the period of British occupation, and its characteristic white stone houses with green shutters, brass knockers and latches—many of them built for British officers—are reminiscent of Georgian England. Southeast of Mahón is the village of Villa Carlos (George Town), a typical British colonial garrison town laid out in 1771 by a British engineer. At the mouth of the port are the ruins of Forts San Felipe and Marlborough; it was for his

refusal to defend the town that Adm. John Byng (q.v.) was shot. Mahón's most important industries are shoe manufacturing, manufacture of imitation jewelry and pearls, and the distilling of gin, and there are handicrafts. The surrounding district is concerned with farming and cattle raising, and Mahón cheese is well known. Mahón is connected by road with Ciudadelà, on the west side of the island, and by air and sea with Barcelona and the other islands.

Mahón (ancient Portus Magonis) bore the name of the Carthaginian general Mago. Under the Romans it was a *municipium*. Barbarossa besieged and captured the city in 1535, and in 1558 it was sacked by a corsair. The British, after their seizure of Mahón in 1708, declared it a free port in 1718. In 1756 it fell into the hands of the French, was restored to the British in 1763, recovered by the Spanish in 1782 and in 1802 finally ceded to Spain.

MAHONE, WILLIAM (1826-1895), U.S. railroad president, Confederate general in the Civil War and U.S. senator, was born in Southampton county, Va., on Dec. 1, 1826. In 1847 he graduated from the Virginia Military institute, took up engineering as a career and by 1860 had become president of the Norfolk and Petersburg railroad. At the outbreak of war in 1861 he entered the Confederate service and participated in almost all the major campaigns of General Lee's army. He was promoted to the rank of brigadier general in March 1864 and major general in August after brilliant fighting around Petersburg.

After the war, Mahone became president of the Virginia and Tennessee railroad and was largely responsible for the development of the Norfolk and Western. Because of opposition from conservative Democrats to his fiscal plans, he formed in 1878 the Readjuster party. While in office, this organization was partly successful in readjusting or scaling down the debt of the impoverished state of Virginia to what it deemed practical limits, and it also promoted education and economic development. In 1880 Mahone was elected to the U.S. senate as a Readjuster but voted with the Republicans. His action led to an even balance of power in the senate and angered the Democrats, who lost their anticipated majority. Mahone was not re-elected to the senate in 1886 and never again had much influence politically. He died at Washington, D.C., on Oct. 8, 1895.

See N. M. Blake, *William Mahone of Virginia: Soldier and Political Insurgent* (1935). (R. D. M.)

MAHONIA, a genus of evergreen shrubs of the barberry (q.v.) family (Berberidaceae) and considered by some as a section of *Berberis*. The mahonias differ from the true barberries mainly in being thornless and in having compound leaves and a calyx of nine sepals. There are about 50 species, found chiefly in Asia, western North America and Central America. Several are cultivated for their ornamental foliage, flowers and fruit, including the Oregon grape (q.v.); the Japanese mahonia (*M. japonica*), native to China; and *M. fortunei*, also native to China and named after the English traveler Robert Fortune.

MAIA, in Greek mythology, the eldest of Atlas' seven daughters, the Pleiades (q.v.), by Pleione, one of the 3,000 daughters of Oceanus. Maia was mother by Zeus of Hermes. She was commonly confused by the Romans with their own Maia or Maïesta, who was the cult partner of Vulcan.

MAIDA, BATTLE OF, a victory won by the British under Maj. Gen. Sir John Stuart over the French under Gen. J. L. Reynier at Maida in southern Italy on July 4, 1806, during the Napoleonic Wars. After Napoleon had crushed the Austrians and the Russians at Austerlitz in Dec. 1805, a French army overran the Bourbon kingdom of Naples. A small British force withdrew from the mainland to Sicily, which was soon threatened with invasion. The British commander, Stuart, soon saw an opportunity to strike back at the French, who were overextended and embroiled with insurgent Calabrians. In conjunction with Adm. Sir Sidney Smith he landed 4,500 men near Maida, in the neck of the Calabrian peninsula, cutting off the southernmost French division commanded by Reynier. Reynier concentrated rapidly and on July 4 had 6,500 men very strongly posted near Maida. Stuart had no

option but to attack him or to re-embark, and was advancing to attack when the French themselves took the offensive.

Reynier and Stuart had already faced each other at the battle of Alexandria, and Maida produced some remarkable parallels. On both occasions the French left a strong position to attack an embarrased British force and were defeated by the good conduct of the British infantry firing volleys in line. Though Reynier's superiority in cavalry and artillery prevented a pursuit, he sustained 2,200 casualties and had to abandon Calabria. The British losses were 327 killed and wounded. Though they subsequently withdrew, the British had achieved a decisive spoiling attack against the French preparations to invade Sicily—a success rendered permanent by the later reinforcement of the island. The campaign is a classic example of the use of sea power to achieve local superiority through mobility and surprise. (P. G. M.)

MAIDENHAIR FERN, the common name for plants of the large genus *Adiantum*, comprising about 200 species of dainty, shade-loving forms with shiny black or purplish stipes and thin delicate fronds or leaf blades, either simple or divided into fan-shaped segments or pinnules. The brownish fruit dots are marginal, and are borne on the underside of the pinnule. The genus is largely of tropical America, with a few species in temperate North America.

A. capillus-veneris, Southern maidenhair or Venus'-hair, occurs in temperate and tropical America, in the warmer parts of the old world and is a popular plant in greenhouses. *A. pedatum*, a larger and beautiful fern, grows in woods from Nova Scotia to Alaska and southward from Florida to Texas. *Adiantum* is an

SOUTHERN MAIDENHAIR FERN (*ADIANTUM CAPILLUS-VENERIS*)

ancient name, meaning unwetted, the foliage shedding raindrops. See also FERN, (J. M. Bl.)

MAIDENHAIR TREE: see GINKGO.

MAIDENHEAD, a municipal borough of Berkshire, Eng., lies on the Thames, 42 mi. N.E. of Reading by road. Pop. (1961) 35,411. The centre of the town and principal shopping area comprises High street, King street and Queen street; the Henry Reitter Fine Art museum, containing prints and drawings, ceramics, carvings, etc., is located by the river near Maidenhead bridge. The first charter was granted by Elizabeth I in 1582. Almshouses were built in 1659, and the Guildhall, founded in 1777, was enlarged in 1878. The stone bridge (1772-77) carries the London to Bath trunk road over the river, and the railway bridge, constructed in 1837-38 to the design of Isambard Kingdom Brunel, has two of the widest brick spans in the world. Maidenhead Thicket and Pinkney's Green, covering 535 ac. of open National trust land, and the summer boating facilities afforded by the Thames, have made the town a popular residential area and "up river" summer resort. In the Thicket is a Roman camp and traces of prehistoric settlement have also been found there. White

Waltham airfield is about 3 mi. S.W. A wide range of light industries includes launch- and boatbuilding.

MAIDENKIRK: see KIRKMAIDEN; JOHN O'GROATS.

MAID MARIAN: see ROBIN HOOD.

MAIDSTONE, a market town and municipal borough and the county town of Kent, Eng., lies on both banks of the Medway 36 mi. E.S.E. of London by road. Pop. (1961) 59,790. There is much evidence of Roman settlement along the Medway valley, and the site of a Roman road runs through the present town. The name Maidstone is derived from the Saxon *Mædesstana*, given as *Meddestane* in the Domesday Book, and is taken to mean "the maidens' stone" (Ekwall). At the time of the Domesday survey Maidstone, as a manor, belonged to the archbishop of Canterbury, and from the reign of John to the Reformation the archbishops had a residence there. The shire moot was held on Penenden heath in the middle ages, and the heath was the scene of executions and great county meetings until the 19th century. Maidstone was an assize town in the reign of Edward I. In 1537 Thomas Cranmer exchanged the manor of Maidstone with the king, and it was granted by Edward VI to Sir Thomas Wyat. Edward incorporated the town in 1549, but this charter was revoked as a punishment for Wyat's rebellion. A second charter was granted by Elizabeth I (1559), a third and fourth by James I (1603 and 1619). Charles II in 1682 called in the old charters and issued a new one. In 1740 this charter was forfeited, and after many petitions a new one (the last) was granted by George II in 1747. Four fairs were granted by the charter of 1549 and a Thursday market, first granted by Henry III to Archbishop Boniface in 1261, was confirmed. A market every second Tuesday in the month was granted in 1751.

The manufacture of linen and woolen goods was increased by Walloons, who settled there in 1567. This was succeeded by papermaking, later the chief industry of the district. Maidstone is also the county centre for the distribution of fruit, grain and hops. The cultivation of hops in the area has been carried on since the 16th century, and there are large breweries and maltings. At East Malling, 4 mi. N.W., is a horticultural research station specializing in experiments in fruitgrowing; Bradbourne house is its headquarters. Other industries include confectionery making, quarrying for Kentish ragstone, agricultural implement manufacturing and printing. Ragstone from the Maidstone district was used in Roman London and medieval times and was utilized in the building of Hampton court, Eton college and the Tower of London. Maidstone is the administrative centre of the Kent County council and of the Kent River board. It is also a commercial centre.

In about 1260 Archbishop Boniface established Newark hospital there for poor travelers; the main building is gone, but the chapel, with modern additions, is St. Peter's church. The rebuilding of the Norman parish church of St. Mary was begun in 1395 by Archbishop William Courtenay, who erected on the same site the present great perpendicular Church of All Saints in Kentish ragstone. Round the church are grouped the medieval Archbishop's palace, now used for public functions; the College of All Saints, founded c. 1395 by Archbishop Courtenay for secular canons; and the Archbishop's stables, now used as a municipal museum of carriages (opened 1946). The grammar school was founded in 1549 and endowed with the estates of the local Corpus Christi fraternity, then dissolved. The medieval hall remains, but in 1871 the school was moved to buildings on a new site. Famous scholars include Christopher Smart, the poet; John Pond, the astronomer; and Adm. Sir Robert Calder. Lawrence Washington, collateral ancestor of George Washington, lived and died (1619) in the town, and there is a memorial tablet to him in All Saints' church. William Hazlitt, the essayist, was born in Maidstone in 1778. A municipal museum and art gallery, with a public library, was opened in 1858 in Chillington Manor house, a Tudor building that is also the headquarters of the Kent Archaeological society. The town hall was built c. 1762-63. There are a girls' grammar school, a technical college and a college of art. Penenden heath was enclosed in 1882 as a public recreation ground. In 1929 the corporation bought the Mote estate of 558 ac. and converted it into a public park. The borough has its own courts of quarter sessions and summary jurisdiction. A new courthouse was opened in 1937.

Cobtree manor, just north of Maidstone on the Chatham road, is generally thought to be the scene of the Dingley Dell skating party in Charles Dickens' *Pickwick Papers*. At West Malling, 6 mi. N.W., is Malling abbey, founded in 1090 by Gundulph, bishop of Rochester, and now restored to use as an Anglican Benedictine nunnery. St. Leonard's tower is all that remains of a Norman chapel. The village has a long cricketing tradition.

MAIDU, once one of the larger Californian Indian tribes; living in the eastern Sacramento valley and Sierra Nevada mountains, they spoke a Penutian (*q.v.*) language. Their population in A.D. 1770 was computed at 9,500 for the three main dialectal divisions (northeastern, northwestern, southern or Nisenan). Their number in the 1960s, including persons of mixed blood, was less than 200. Language divisions correspond only in part with physiography and cultural cleavages, and ethnologists recognize valley, foothill and mountain cultural types. Political organization was based upon the tribelet, comprising a series of villages with an average total of about 250 persons and holding exclusive rights to 100 to 200 sq.mi. of territory. A chief, usually a wealthy man from the largest village, was political head of the tribelet. The Maidu, together with the Wintun of the western Sacramento valley and the Pomo (*q.v.*) in the southern Coast range, best exhibited central Californian culture as judged by complexity of the spirit-impersonating Kuksu religion, basketry manufacture, and numbers of large, stable villages. This cultural peak was supported by an unusual abundance of such food as salmon, deer, elk, acorns and grass seeds.

BIBLIOGRAPHY.—R. L. Beals, *Ethnology of the Nisenan* (1933); R. B. Dixon, "The Northern Maidu," *Bull. Amer. Mus. Nat. Hist.*, vol. 17 (1905); A. L. Kroeber, *Handbook of the Indians of California* (1925); U.S. Department of the Interior, *United States Indian Population and Land* (1961). (R. F. HA.)

MAIDUGURI: see YERWA-MAIDUGURI.

MAIKOP (МАЙКОП), a town and administrative centre (since 1936) of the Adygei autonomous *oblast* of Krasnodar krai, U.S.S.R., stands on the right bank of the Belaya river, where it issues from the Caucasian foothills. Pop. (1959) 82,135. Industries include metalworking and machine building (especially for the timber and petroleum industries), a wide range of timberworking (particularly furniture and parquet making), tannin extracting and food processing. Maikop oil fields are to the southwest with the main centres at Apsheronsk, Neftegorsk and Khadyzhensk. In 1950 a hydroelectric plant was completed on the Belaya. The many mineral springs in the neighbourhood have given Maikop some importance as a spa. The town has a pedagogic institute and an Adygei language, history and literature institute. It was founded in 1857–58 as a Russian fortress and was captured by the Germans during World War II. (R. A. F.)

MAIL: see POSTAL SERVICES.

MAILÁTH, JANOS, COUNT (1786–1855), Hungarian man of letters, the interpreter of Magyar culture to the Germans and the sympathetic historian of the Habsburg monarchy, was born in Pest on Oct. 5, 1786, the son of Count József Mailáth, an imperial minister of state and a member of a well-established family. Having studied philosophy at Eger and law at Győr, he obtained a post in the government service but soon had to resign because of an injury to his eyesight. Devoting himself to literary work, he edited two important collections of medieval German poetry (1818, 1819) and published some German verse of his own (1824) before producing his German translations of Hungarian poems (1825, 1829), his presentation of Hungarian folklore (*Magyarische Sagen, Märchen und Erzählungen*, 1825) and his five-volume history of the Magyars (also in German, 1828–31). There followed other works on special aspects of Hungarian history and also the five-volume *Geschichte des oesterreichischen Kaiserstaats* (1834–50), more perceptive than any preceding study of the Habsburg empire. Mailáth also wrote on mnemonics (1842) and on the healing power of animal magnetism (1852).

Mailáth stood apart from both the revolutionary and the conservative schools of thought. In 1848 he left Vienna for Munich. At last, finding himself destitute, he became despondent and made a suicide pact with his daughter Henrika, who had long been his amanuensis: on Jan. 3, 1855, they tied themselves together by the

wrists, weighted their clothes with stones and threw themselves into the Starnberg lake.

MAILLART, ROBERT (1872–1940), Swiss engineer, renowned for his pioneering work in reinforced-concrete flat-slab construction and the unsurpassed beauty and elegance of his bridges, was born in Bern, Switz., June 2, 1872. He was educated at the Federal Institute of Technology, Zürich (1890–94); then worked in France with François Hennebique, who had the first reinforced-concrete construction firm. In 1902 Maillart founded his own engineering firm in Zürich. He went to Russia in 1912, where he constructed factories and warehouses in Kharkov, Riga and St. Petersburg (Leningrad) for Swiss companies. After the Russian Revolution he returned to Switzerland financially ruined. In 1919 he again founded an engineering firm and continued construction until his death in Zürich on May 4, 1940.

Among Maillart's works are bridges, spun airily over space, belonging to the purest expression that the modern era has been able to achieve. They include the Tavanasa bridge (1905), span 170 ft.; Salginatobel bridge (1929–30), span 307 ft.; Thur bridge (1933), span 240 ft.; a bridge over the Arve river near Geneva (1936–37), span 187 ft.; and bridges at Lachen (1940) and over the Simme river (1940). His was the first mushroom column, flat-slab construction, for a warehouse in Zürich (1910).

See E. B. Mock, *The Architecture of Bridges* (1949); S. Giedion, *Space, Time and Architecture* (1954). (S. GR.)

MAILLOL, ARISTIDE (1861–1944), French sculptor, whose primary importance rests on his monumental studies of the nude, was born at Banyuls-sur-Mer, Pyrénées-Orientales, on Dec. 8, 1861. At first a painter, he studied at Perpignan and, from 1882 to 1886, in Paris. Like many young artists at this time, he then abandoned easel painting, taking up tapestry and wood carving and, about the turn of the century, began to work on a grand scale in clay, marble and bronze. At that time Maillol began to be influenced by the "synthesist" movement of Paul Gauguin (*q.v.*) and by Maurice Denis and his concern with statuesque calm, order and unity at the expense of detail.

This equipment was strengthened in the first decade of the 20th century by a reappreciation of the archaic art of Greece (which Maillol visited in 1909); and it gave his work qualities which at once distinguished it from the intensely emotional and disrupted forms of Auguste Rodin, then powerfully influential.

Closely based on the living model, Maillol's work is nonetheless formal and he is preoccupied with over-all unity and balance. The emotional force of his work depends on disciplined relationships of mass and direction, and this control distinguishes it again from Rodin's frequent dependence on accidental effects of surface. Among Maillol's large works are the reclining figure of "Fame" in the Tuilleries gardens, Paris (a monument to Paul Cézanne); the war memorials at Elne, Céret and Port Vendres, the standing figure of "Flora" (1911); and the "Crouching Woman" made for his friend Count Kessler. There is a portrait head of Auguste Renoir (1907), between whose sculpture and Maillol's there is an affinity. He also worked in high-relief in stone and made fine terra-cotta statuettes, and his drawings and the book illustrations of his late years are of high quality. He died after a road accident near his birthplace in Oct. 1944. (D. C. T. T.)

MAILLY, LOUISE JULIE DE MAILLY-NESLE, COMTESSE DE (1710–1751), the eldest of three sisters who became mistresses of Louis XV of France, was born on March 16, 1710, the daughter of Louis de Mailly, marquis de Nesle. In 1726 she married her cousin Louis, comte de Mailly. Though her liaison with the king began in 1733, she behaved unobtrusively and was not acknowledged as his mistress until 1738. In the following year the king extended his favours to her more ambitious sister Pauline Félicité, marquise de Vintimille, who used her position to advance the interests of the future marshal de Belle-Isle but died on Sept. 9, 1741. Madame de Mailly then regained some influence with the king and continued her sister's policy of supporting Belle-Isle. She was soon supplanted by another sister, Marie Anne, marquise de la Tournelle and later duchess de Châteauroux, who procured her dismissal from court at the end of 1742. She died in Paris on March 30, 1751.

See A. Dietrich, *Les Maîtresses de Louis XV* (1881); and works cited under CHATEAUX, M. A. DE MAILLY-NESE, DUCHESSE DE.

MAIL-ORDER BUSINESS, a method of merchandising in which the seller's offer of merchandise is made through a circular, catalogue or advertisement placed in a newspaper or magazine and the buyer places his order by mail. Delivery of goods has traditionally been made through freight, express or parcel post on a cash-on-delivery basis. While mail-order merchandising in the United States has developed mainly as a method of retailing, there also are a few wholesale distributors who do a large volume of business on a mail-order basis.

Retail mail-order selling developed primarily as a method of selling to rural customers, but it now also includes millions of urban customers. For the convenience of city residents the leading companies have supplemented their traditional direct-by-mail facilities with catalogue-order offices in strategic locations and, in some cases, with round-the-clock telephone ordering services and the promise of delivery by truck within 48 hours. In some areas merchandise delivery is made within 24 hours after the order is placed.

Most mail-order businesses are small specialty sales firms selling by the traditional method. Department stores also do a significant volume of business through their mail-order divisions. The vast bulk of mail-order business, however, is accounted for by a few firms selling general merchandise lines. The multibillion-dollar volume of Sears, Roebuck and Company and Montgomery Ward and Company accounts for most of the retail mail-order sales business in the United States. Though dwarfed by these two giants, Spiegel and Aldens, Inc. are also very large establishments.

Responding to major population shifts, the two largest mail-order companies established hundreds of retail stores across the country in the years after 1925. By mid-century the retail store sales volume of the largest firms exceeded that of their mail-order divisions. In addition to conventional over-the-counter selling, these retail stores included facilities for customers wishing to order goods through catalogues. Credit sales also became important in the mail-order business.

Mail-order operations have been known in the U.S. in one form or another since colonial days, but not until the latter part of the 19th century did this form of distribution assume a significant role in domestic trade. The agricultural expansion in the U.S. together with the completion of the continental railroad network combined to provide a basic opportunity for a new form of distribution. The general merchandise mail-order houses developed to serve the market that was not being adequately served by conventional retailing outlets in rural areas. One of the impelling forces leading to the original success of the mail-order companies in rural markets was the bringing of a variety of merchandise to the isolated farm buyer at comparatively low prices. This great growth was stimulated by a postal-rate structure which encouraged the wide dissemination of the early mail-order papers and later the distribution of catalogues. The establishment of the parcel-post system in 1913 added another important auxiliary to the continued expansion of mail-order operations.

Of significant importance in encouraging the growth of the early mail-order companies was the general antagonism U.S. farmers felt toward middlemen. The American Grange was especially vocal in expressing the resentment of the agricultural population toward what farmers considered the excessive size of distributors' trading margins. The early advertising copy of the mail-order companies capitalized effectively upon this attitude of many farmers toward the merchant class, and the earliest years of Montgomery Ward and Company saw a close association between the company and the Grange. Members of the Grange were given special inducements to trade with Montgomery Ward when the company was founded in 1872.

The established mail-order houses came to be uniformly respected by both their customers and their competitors for adopting policies of full guarantees on merchandise and of liberality in making adjustments. Although the companies were leaders in the movement for accurate and informative advertising of essentially reputable merchandise, there had always been some exceptions. Indeed, the early years of the business saw intensive advertising

campaigns which attempted to exploit every possible opportunity to glorify the merchandise and to impel the incautious customer to buy. Modern mail-order catalogues, however, are generally models of propriety and truthfulness in advertising.

The most successful mail-order companies have enjoyed certain sources of economy common to large-scale merchandising. They buy in large quantities; they frequently order merchandise manufactured to their own specifications; and in many cases they arrange for the production of their orders on a schedule which permits the supplier to sell at lower margins than he would otherwise demand. In some cases the large firms contract for the entire output of particular manufacturers, and occasionally the mail-order company is completely integrated in terms of ownership of factory outlets, although this is not common.

Apart from the economies of large-scale buying and selling, the mail-order operation offers certain other opportunities for operating economies since the mail-order plants themselves are essentially warehouses and may be located in low-rent areas. Further economies are achieved in the handling and shipping of merchandise. Machines and mechanical aids of many types are employed. Manpower is eliminated wherever a machine will be more efficient. Pneumatic tubes, endless-belt conveyers, chutes and electric trucks are used in the distribution of orders to the numerous merchandise departments into which the mail-order house is organized. Paralleling these mechanical facilities, personal effort is organized along highly specialized lines. Throughout the entire system of buying, handling and shipping, substantial savings of time and money are achieved and are reflected in the retail prices found in the mail-order catalogue, the primary selling instrument of the important mail-order firms.

The mail-order houses contributed substantially to improving the efficiency of retail distribution in the United States. Perhaps more important than any other single service was their effect in breaking the local monopolies of retail stores in once isolated areas by providing rural buyers with a feasible means for purchasing a wide variety of merchandise at relatively low prices.

While company sales volume of the largest mail-order firms is enormous, the relative importance of mail-order sales to retail trade in general is not great. Mail-order sales constituted less than 1% of the total retail sales volume in the United States in the early 1960s.

MAIMANA, a town and capital of Maimana province in northwest Afghanistan, lies 2,850 ft. above sea level in a green valley encircled by the northern foothills of the Band-i-Turkistan range, 140 mi. W.S.W. of Mazar-i-Sharif. Pop. (1962 est.) 50,967. It was formerly the capital of a small khanate, long in dispute between Bukhara and Kabul until its subjugation by Abdurrahman Khan in 1868. The khanate was allotted to Afghanistan by the Russo-Afghan boundary commission of 1885. The town's former fortified character has disappeared. On a mound from where, before its destruction in the late 1950s, the old castle dominated the town, stands a modern cinema in a park. Maimana has a small airport with services to Herat, Mazar-i-Sharif and Kabul. Roads to Herat (about 280 mi.) and Mazar-i-Sharif (about 220 mi.) are difficult and impassable during spring floods, and their eastern stretches have patches of soft sand. There is no road to the Soviet border, 30 mi. away. Maimana is a small commercial centre.

MAIMANA PROVINCE is a minor province bounded west by the Turkmen Soviet Socialist Republic, east by Shibarghan, south by Ghor and southwest by Herat. It consists of mountains with fertile valleys to the south, where are the towns of Maimana and Qaisar, and desert plains to the north, with the towns of Daulatabad, Shireen Tagao and Andkhui, another former khanate, which has preserved its picturesque character. The people are mostly Uzbeks with some Pathans and Turkmens in the north. The main occupations are carpet weaving, sheep grazing and the preparation of karakul lambskins. Pop. (1962 est.) 435,518. (X.)

MAIMBOURG, LOUIS (1610-1686), French Jesuit and

historian, an energetic defender of Gallican liberties in his *Traité historique de l'établissement et des prérogatives de l'Église de Rome et de ses évêques* (1685; new ed., 1831). Born at Nancy on Jan. 10, 1610, he entered the Society of Jesus at the age of 16. His works include *Histoire du lutheranisme* (1680) and *Histoire du calvinisme* (1682), the latter being useful to the French government as propaganda for the revocation of the Edict of Nantes. His defense of French liberties in his *Traité* was bitterly resented by Pope Innocent XI, who ordered the Jesuits to expel him. Louis XIV granted him a pension and a retreat at the abbey of St. Victor, Paris. He died on Aug. 13, 1686.

His works were published in 14 volumes (1686–87).

MAIMING, mutilation, a physical injury which involves the loss of, or incapacity to use, a bodily member. Maiming or mutilation is and has been practised by many peoples with various ethnical and religious significances, and was a customary form of punishment on the principle of an "eye for an eye." (See **MUTILATIONS AND DEFORMATIONS**.)

In law "maiming" was made a criminal offense; the old law term employed for a special case of maiming of persons was mayhem (*q.v.*), an Anglo-French variant form of the word. The punishment incurred for maiming of cattle in Great Britain was set at 13 to 14 years of penal servitude. Malicious injury to other animals was made a misdemeanour punishable on summary conviction. For a second offense the penalty was set at imprisonment with hard labour for more than 12 months under the Malicious Damage act of 1861. In both British and U.S. law maiming means the permanent injury of the animal; wounding or otherwise mistreating an animal is a separate offense.

MAIMON, SALOMON (c. 1754–1800), Jewish philosopher who was acknowledged by Kant to be the most acute of his critics, was born about 1754 at Nieswiez in Polish Lithuania and was married off by his father at the age of 11. He gained a remarkable proficiency in Hebrew, studying outside the conventional limits of the Talmud, and acquired a particular reverence for Maimonides (*q.v.*), in whose honour he took the surname Maimon instead of the original patronymic Ben Joshua. In 1770 he estranged himself from his orthodox coreligionists by a commentary on Maimonides' *Guide of the Perplexed*. Eight years later he left Poland for Königsberg to begin a life of material insecurity and wandering over northern Europe only terminated in 1790 when he was offered the retreat on the estate of Count Adolf Kalkreuth at Nieder-Siegersdorf (Silesia), where he died on Nov. 22, 1800.

Nearly all Maimon's philosophical works were published during the years 1790–1800, including the two by which he is best remembered: the autobiography edited for him as *Salomon Maimons Lebensgeschichte* by Karl Philipp Moritz (1792); and *Versuch über die Transcendentalphilosophie* (1790), formulating his objections to Kantian philosophy. In this work Maimon seizes upon the fundamental incompatibility of a consciousness which can apprehend, yet is separated from, the thing-in-itself. That which is object of thought cannot be outside consciousness; just as in mathematics $\sqrt{-1}$ is an unreal quantity, so things-in-themselves are *ex hypothesi* outside consciousness, that is to say, unthinkable. The Kantian paradox he explains as the result of an attempt to explain the origin of the "given" in consciousness. The form of things is admittedly subjective; the mind endeavours to explain the material of the given in the same terms, an attempt which is not only impossible but involves a denial of the elementary laws of thought. Knowledge of the given is, therefore, essentially incomplete. Complete or perfect knowledge is confined to the domain of pure thought, to logic or mathematics. Thus the problem of the thing-in-itself is dismissed from the inquiry, and philosophy is limited to the sphere of pure thought. The Kantian categories are, indeed, demonstrable and true, but their application to the given is meaningless and unthinkable.

By this critical skepticism Maimon takes up a position intermediate between Kant and Hume. Hume's attitude to the empirical is entirely supported by Maimon. The causal concept, as given by experience, expresses not a necessary objective order of things, but an ordered scheme of perception; it is subjective and cannot be postulated as a concrete law apart from consciousness.

Maimon's other published works include *Philosophisches Wörterbuch* (1791); *Über die Progressen der Philosophie* (1791); *Versuch einer neuen Logik* (1794); and *Kritische Untersuchungen über den menschlichen Geist* (1797).

See Hugo Bergman (ed.), *The Autobiography of Solomon Maimon*, with useful commentary (1954).

MAIMONIDES (MOSES BEN MAIMON) (1135–1204), also known from his initials, with his title rabbi, as RAMBAM; Jewish philosopher, physician and master of rabbinic literature, was born in Córdoba, Spain, of an illustrious Jewish family and educated by his learned father. When Córdoba fell to the Almohads in 1148 and the position of the Jews became intolerable, the family emigrated first to Morocco, then for a short while to Palestine and finally to Egypt. Maimonides eventually settled in Fostat, a suburb of Cairo, where he attained the position of *nagid* or accredited leader of Egyptian Jewry. He was appointed court physician to Saladin and was invited by King Richard I to come to England but refused the invitation.

Maimonides' greatest work in the rabbinic field is his *Mishneh Torah*, a kind of *summa theologiae* of Judaism, composed in an elegant and concise Hebrew, arranged in 14 books and offering a systematic presentation of the entire content of the rabbinic tradition. It was preceded by his *Commentary on the Mishna* and by the *Book of Commandments*, both written in Arabic. The *Mishneh Torah* secured for Maimonides a commanding position in the development of rabbinic law and represents the first of a series of authoritative codes. From his early youth, Maimonides was attracted to Aristotelian philosophy as taught by al-Farabi and by Avicenna. At the age of 16 he composed a *Treatise on the Terminology of Logic*; and his *Commentary on the Mishna* embodies a fair amount of philosophy, especially in the *Eight Chapters* prefacing his comments on the tractate *Avot*. The same applies to his code, which opens with an outline of his metaphysics and ethics. His celebrated *Guide of the Perplexed* contains the ripe fruit of his philosophical thinking and exercised considerable influence on both Jewish and Christian scholasticism. Written in Arabic, it seeks to interpret the biblical and rabbinic theology in terms of Neoplatonic Aristotelianism.

The first book of the *Guide* discusses the figurative meaning of anthropomorphic expressions applied to God in the Scriptures and examines the propriety of the various types of attributes or predications of God. The essence of God can be neither defined nor described. Existence is not something added to, but implied in, the essence of God. The *via negativa* is the only admissible way of speaking about God's essence; that is to say, we can deny all positive statements about God which imply a deficiency. But we may also admit "attributes of action" such as justice, love, etc., seeing that they do not touch upon the mystery of his hidden essence and describe only God's relation to the world in terms of cause and effect. The first book concludes with a comprehensive statement of the principles of the Muslim *mutakallim* and their refutation. The second book proves the existence of God by the argument of the unmoved mover and by the distinction between the necessary and the possible and between the necessary and the contingent. Aristotle's cosmology is accepted in outline and the separate intelligencies of Neoplatonic Aristotelianism moving the celestial spheres are identified with the angels of Scripture. Aristotle's doctrine of the eternity of the world Maimonides finds less acceptable, not because it contradicts the plain meaning of Scripture (this could, if necessary, be interpreted allegorically) but because it runs counter to the fundamental biblical notion of a God not bound by necessity and creating the world freely. Maimonides makes the point that unless we allow for the free operation of God's will the irregularities in the planetary motions cannot be explained. The second book also discusses the nature of prophecy: the prophets of the Bible are described as combining intellectual insight with the strongest imagination: their visions represent intuitive intellctions concerning the spiritual world and their dreams future events. Following al-Farabi's *The Model State* and Avicenna's discussion of prophecy, Maimonides sees in the type of the prophet a kind of Platonic philosopher-king, the lawgiver of the ideal state. The

third book treats of the nature of evil, of providence, of design in nature, of the historical background of the biblical ritual (this section is important as an early essay in comparative religion) and of moral virtues as steppingstones to the contemplative life. (See also JEWISH PHILOSOPHY.)

Editions of the *Guide* are: by S. Munk, Arabic text with French translation and valuable notes, 3 vols. (1856-66), English translation by M. Friedlander, 3 vol. (1881-85), and reissue, 1 vol. (1925), and German translation by A. Weiss, 3 vol. (1923). There is also an English translation of selected passages by C. Rabin, with introduction and commentary by J. Guttmann (1952).

Other texts include the *Treatise on the Terminology of Logic*, edited with English translation by I. Efros (1937-38); *Eight Chapters*, English translation by J. I. Gorfinkle (1912); and sections from the *Mishneh Torah* in English translation by M. Hyamson (1949 et seq.).

See bibliographies compiled by J. L. Gorfinkle in I. Epstein (ed.), *Moses Maimonides, 1135-1204*, pp. 229-248 (1935); and by G. Vajda in *Judische Philosophie*, pp. 20-24 (1950).

MAIN, a river of Germany, 325 mi. long and the most important right-bank tributary of the Rhine. It has two sources, the Weisser Main (White Main) which rises in the Fichtelgebirge, and the Roter Main (Red Main) which, rising on the eastern slope of the Frankish Jura, flows past Bayreuth. They unite near Kulmbach and the Main then flows northwest round the north end of the Frankish Jura to Bamberg. There it receives its chief tributary, the Regnitz (left), flows amid vine-clad hills to Würzburg and thence between the forest-covered Spessart and Odenwald ranges to Gemünden. There it is joined by the Fränkische Saale (right) and, turning abruptly south, receives the Tauber (left) at Wertheim. It flows due north to Aschaffenburg, then west passing Frankfurt to join the Rhine above Mainz. The river is navigable upstream as far as Würzburg by 1,000-ton barges and to Bamberg by 600-ton barges. The old Ludwig canal links the Regnitz and the Danube. A new canal alongside to take 1,500-ton barges is planned from Bamberg to Kelheim on the Danube.

(R. E. DL.)

MAINA (MANI) denotes that part of the Peloponnese occupied by the mountain range of Taygetus from Sparta to Cape Matapan (Tainaron), the modern eparchies of Oetylos (Oitylon) and Gythium (Ythion), Greece. The inhabitants of this natural fortress were less affected than those in more accessible regions by movements of population and political changes. They did not become Christians until the 9th century; and they resisted in turn the Byzantine administration, the barbarian invaders, the Latin princes of Achaia and the Turks. Nevertheless, the feudal keeps on the western side erected by the Latin princes in the 13th century show that the Mainotes did not entirely escape control; and during the 15th to the 17th centuries they accepted the overlordship of a family claiming to belong to the Comneni of Trebizond. Later they were brought into some measure of submission to the Turks. The real power, however, was vested in the turbulent chieftains of the hundred villages in which the Mainotes lived. As the soil was poor, many took to piracy and others migrated to Corsica.

During the 18th century the family of Mavromikhalis (Black Michael) established a supremacy and led the chieftains to join the rising of 1770 in the Peloponnese instigated by the Russians. Though defeated, the Mainotes yet managed to secure in 1777 an even greater degree of independence than they formerly enjoyed. In 1819 Petros Mavromikhalis (Petro Bey) and other chieftains joined the Philiki Etaireia. They were among the first to rise in 1821 at the outbreak of the War of Greek Independence (q.v.) and their military contribution to the cause was important. But like other Greek chieftains, Petro Bey and his captains were antagonistic to central institutions. They opposed the government in the civil war of 1823 and in May 1830 defied Kapodistrias, who was assassinated by Georgios and Konstantinos Mavromikhalis at Nauplia on Oct. 9, 1831. Maina remains one of the wildest and lesser known parts of Greece.

See P. L. Fernald, *Maini: Travels in the Southern Peloponnese* (1958).

(D. DN.)

MAINE, SIR HENRY JAMES SUMNER (1822-1888),

English jurist and historian, a pioneer in the study of comparative law, was born on Aug. 15, 1822. He was educated at Christ's hospital and Pembroke college, Cambridge, where he excelled in classical studies. From 1847 to 1854 he was professor of civil law at Cambridge university and also began lecturing on Roman law at the Inns of Court, the legal centre in London. These lectures formed the groundwork for his first book, *Ancient Law* (1861; new ed., 1930), which made his reputation at one stroke. Its object was "to indicate some of the earliest ideas of mankind, as they are reflected in ancient law, and to point out the relation of those ideas to modern thought." Historical in approach and objective in method, the work drew upon Roman law, systems of both western and eastern Europe, laws of India and primitive law in order to trace and define basic concepts. Although some of his statements necessarily were modified or invalidated by later research, Maine helped put the study of comparative jurisprudence on a sound historical footing. *Ancient Law* also was influential in political theory and, because of its controversial theories on primitive law, in anthropology.

From 1863 to 1869 Maine was a legal member of the council of the governor-general in India, where he was largely responsible for plans for the codification of Indian law. He also served as vice-chancellor of Calcutta university. Upon his return to England he became, in 1869, the first professor of historical and comparative jurisprudence at Oxford and, in 1887, professor of international law (a subject that occupied his later years) at Cambridge. The recipient of many honours during his lifetime, he died on Feb. 3, 1888, at Cannes, France.

Maine's other books include *Village Communities in the East and West* (1871); *Early History of Institutions* (1875); *Dissertations on Early Law and Custom* (1883); *Popular Government* (1885). See also JURISPRUDENCE.

BIBLIOGRAPHY.—M. E. Grant Duff, *Sir Henry Maine* (1892); W. Graham, *English Political Philosophy From Hobbes to Maine* (1899); P. Vinogradoff, *The Teaching of Sir Henry Maine* (1904).

MAINE, LOUIS AUGUSTE DE BOURBON, DUC DU (1670-1736), French prince, was born on March 31, 1670, probably at St. Germain, the eldest to survive of Louis XIV's children by the marquise de Montespan. In Dec. 1673 he was legitimated and given the title duc du Maine. He received a good education and had his first taste of military service in 1688, when he took part in the siege of Philippsburg. He served with honour and some distinction in succeeding campaigns in the Low Countries until 1702.

Maine received a great flow of honours from Louis XIV, who loved him dearly. On May 5, 1695, Louis accorded him a rank intermediate between the legitimate princes of the blood and the other peers, who bitterly resented this promotion; and on July 29, 1714, another royal decree gave him the same rank as the legitimate princes, with the right of eventual succession to the throne. The king tried to reinforce this ruling by the provisions of his will: not only was Maine given a place in the projected regency council, but he was also to have the guardianship of Louis XV and the command of the royal guards. When Louis XIV died, however, his nephew Philippe, duc d'Orléans, had himself made sole regent and withheld the command of the guards from Maine, who was left only with control over the new king's education, not the guardianship. Next, in July 1717, Maine was deprived of his status as a prince of the blood and of his right of succession; and in Aug. 1718 he lost his control over the king's education.

Maine had been married on March 19, 1692, to Anne Louise Bénédicte de Bourbon-Condé (1676-1753; see CONDÉ, PRINCES DE). At first preoccupied with brilliant social and literary festivities at Sceaux, she had turned her ambitions to politics in the last years of Louis XIV's reign. Angered by the regent's treatment of her husband, she became the moving spirit in a conspiracy between the Maines and the Spanish ambassador Antonio Giudice, prince de Cellamare, whose instructions were to try to secure the French regency for Louis XV's uncle, Philip V of Spain. Guillaume DuBois, the regent's minister, soon discovered what was afoot, and Maine, the duchesse and Cellamare were all arrested (Dec. 1718). Maine and his wife were imprisoned for just over a year. He

then retired from public life and even became reconciled with Orléans. For a time he was separated from the duchesse, who retired to the château at Sceaux to revive its former splendours to some extent. Maine died there on May 14, 1736. The duchesse died in Paris on Jan. 23, 1753.

See W. H. Lewis, *The Sunset of the Splendid Century* (1955). (B. J. R.)

MAINE (LE MAINE), an old province of France, bounded north by Normandy, east by Orléanais, southeast by Touraine, south by Anjou and west by Brittany and corresponding approximately to the modern *départements* of Mayenne and Sarthe (*q.v.*), though the province included Domfront (now in Orne) and Montoire (now in Loir-et-Cher) and did not include Le Lude, La Flèche, Château-Gontier or Craon (from Anjou).

The two Gallo-Roman *civitates* of the Cenomani and of the Diablintes, with their capitals respectively in the towns later called Le Mans (*q.v.*) and Jublains (between Mayenne and Evron), were merged in the middle of the 5th century into a single *pagus* or district of Le Mans. From the same time bishops of Le Mans are recorded. The 9th century was marked by Breton and Viking incursions. Hereditary counts, beginning with a warlord called Roger in the 890s, usurped much of the bishops' temporal authority; but in the 11th century their countyship was compressed between Normandy and Anjou. Maine fell to Anjou early in the 12th century and then, with Anjou and Normandy, to the French king Philip II Augustus at the beginning of the 13th. Louis IX of France granted it to his brother, the future Charles I of Naples, in 1232, but Charles II of Naples transferred it in 1290 to Charles of Valois, whose grandson John II of France granted it in 1356 to his son Louis (later Louis I of Naples). When the latter's great-grandson Charles died childless in 1481, Maine reverted to the French crown. Economically the great achievement of the middle ages in Maine was the clearing of wide tracts of woodland and scrub for agriculture and settlement in the 11th–13th centuries. In the Hundred Years' War the country was several times overrun by the English and occupied by them from 1425 to 1448.

In the last centuries of the *ancien régime* Maine was a province under a military governor with his seat at Le Mans, but was administered, with Anjou and Touraine, by the intendant of the *généralité* of Tours.

MAINE, popularly called the "Pine Tree" state, is the most northeasterly state of the United States and the largest state in New England; it was admitted to the union in 1820 as the 23rd state. It is bounded on the northwest by the Canadian province of Quebec; north and east by New Brunswick; south-southeast by the Atlantic ocean; and west by New Hampshire. It has an area of 33,215 sq.mi., 2,203 sq.mi. being inland water surface; in size it ranks 39th among the states.

The state capital is Augusta (*q.v.*). The white pine is the state's official tree, the white-pine cone and tassel the state flower and the chickadee the state bird. The flag is a blue field upon which is embroidered the state's coat of arms.

PHYSICAL GEOGRAPHY

Physical Features.—Maine lies between the extremes of approximately 43° 4' and 47° 28' N. lat. and 66° 57' and 71° 7' W. long. Considering the area as a whole, the surface of Maine is a gently rolling upland, above which rise mountain peaks, isolated and in clusters, and below which are numerous river valleys. The highest peak is Mt. Katahdin (5,268 ft.), other high mountains being Saddleback mountain (4,116 ft.), Mt. Abraham (4,049 ft.), Mt. Bigelow (4,150 ft.) and Mt. Blue (3,187 ft.). A little north of this line of mountain peaks is the water parting which divides the state into a north slope and a south slope. The north slope, though hilly in the middle and west, is so poorly drained that swamps abound in all sections. The south slope, which contains nearly all the mountains and is generally more hilly, has a mean descent toward the sea of about seven feet to the mile.

During the period of the great continental glaciation, Maine was overrun by the glacial icecap, which left more than 1,600 lakes scattered throughout the state. Few other states have so many large lakes of such beauty, and they contribute largely to a

constant supply of water power, for which the rivers of southwest Maine are exceptionally well adapted. Moosehead lake (about 117 sq.mi.) is the largest lake in Maine and the largest inland body of water wholly in New England; the Kennebec river is its principal outlet. Other lakes, such as the Rangeleys, the Chesuncook and Twin lakes, on the Penobscot, and the Grand lake, at the headwaters of the St. Croix river, equal Moosehead's picturesque setting.

Another important feature of Maine's physiography is the irregular coast line with its numerous islands and bays and many good harbours. The shortest distance between extremities of the coast is only 225 mi., but because of projections and indentations the coast line measures about 2,500 mi. West of the mouth of the Kennebec river are marshes and low grassy islands, but east of the river the shore becomes much bolder and rises in precipitous cliffs. Casco, Penobscot and Passamaquoddy bays are representative of the capacious and well-protected harbours.

The principal river systems of Maine are the St. John on the north slope and the Penobscot, Kennebec, Androscoggin and Saco with numerous falls and rapids, on the south slope.

Climate.—The climate of the state is moist and rather cold. The precipitation is about 42.5 in. annually and is distributed very evenly throughout the year, 10 to 11 in. of rain or its equivalent in snow falling each season. The snowfall varies from about 60 in. on the coast to more than 100 in. on the north slope, the average for the state being about 83 in. The summers are short, with a growing season of only about 4½ months. The mean summer temperature is about 62° F. (16° C.), the mean winter temperature approximately 20° F. (−7° C.). The mean annual temperature for the entire state is 42° F.

Soil.—The soil types, though exceedingly varied, are in general poor, as a result of glaciation. The most productive area of the state is the potato-growing region in Aroostook county.

Vegetation.—Maine once was famous for its virgin stands of white-pine trees, and there still exist great numbers of white pine, fir and spruce. Among the other kinds of trees are hemlock, balsam fir, red and bur oak, white and yellow birch, sugar and mountain maple, box elder, tamarack, red spruce, white cedar, black willow, aspen, beech, white or American elm (especially typical of New England), mountain ash and wild fruit trees. The flowers and blossoming shrubs are those that are common to the north temperate zone. Among the more widely distributed ones are the anemone, all kinds of asters, wild bergamot, bittersweet, black-eyed Susan, clover, daisy, blue flag, goldenrod, many varieties of lilacs and the trailing arbutus. Devil's-paintbrush, pinks, rhodaras, wild roses and violets also grow in profusion.

Animal Life.—Perhaps the most numerous of the wild animals common to Maine are deer, more than 40,000 of which are killed annually by hunters. Others are black bear, beaver, red fox, otter, mink, weasel, squirrel, rabbit, porcupine, muskrat, woodchuck and wildcat. Game birds native to the state include the Canada goose, wood duck, ruffed grouse, pheasant and many others. Other birds are the American eagle and varieties of owls and loons, and among songbirds, robins, orioles, bobolinks, kingbirds, swallows and chickadees. Trout, pickerel and salmon are plentiful in the lakes; coastal fish include tuna, cod and flounder.

Parks, Memorial Sites and Recreation.—Established in 1919 as Lafayette National park, with headquarters at Bar Harbor, Acadia National park is the only national park in New England and the oldest east of the Mississippi river. Baxter State park, in the northern Maine wilderness, has Mt. Katahdin as its chief attraction; Mt. Katahdin marks the beginning of the Appalachian trail (see APPALACHIAN MOUNTAINS). Other state parks of interest include Aroostook State park, near Presque Isle, and Fort Knox State park, at Prospect, on the site of a fortification built after the Aroostook War. Among the memorial sites are Fort Edgcomb memorial, on Davis Island, built in 1808 to defend Wiscasset harbour; Fort Machias memorial, off which the Revolutionary schooner "Margaretta" was captured early in the Revolutionary War; Fort McClary memorial, the first recorded fortification of the Massachusetts bay colony on the Maine side of the Piscataqua river; Fort George memorial, at Castine, which has earthworks and

fortifications built by the British in 1779; Fort William Henry memorial, at Bristol; and Fort Popham memorial, at Phippsburg, on a site fortified during the Revolutionary War and the War of 1812 and meant to guard the entrance to the Kennebec river.

Maine's position as a favourite resort for summer vacationists dates from about 1870, when camps, summer hotels and boarding-houses began to multiply throughout the state. Maine is now one of the nation's leading vacation spots.

HISTORY

Discovery and Settlement.—Most historical scholars believe that Maine was sighted by Norsemen about A.D. 1000, but for lack of definite evidence the credit of discovering Maine passes to others. John Cabot probably saw Maine on his second voyage to the new world in 1498. Among the explorers of the 16th and early 17th centuries who reached Maine were Giovanni da Verrazano (1524), Pierre du Guast, sieur de Monts (1604), George Weymouth (1605) and John Smith (1614). Smith explored and mapped the coast and gave to the country the name New England.

At the time of these early explorations there were probably at least 25,000 Indians of the Algonkian group living in Maine, separated from the main body of Algonkians by their bitter enemies the Iroquois. They lived in semipermanent villages along the main rivers and subsisted on fish, game and a primitive agriculture, which featured corn and other garden vegetables. Property was owned in common. The manner of government varied from tribe to tribe.

In 1603 De Monts received from the king of France a grant of all the land between the site of Philadelphia and Newfoundland, and in 1604 he established a colony on St. Croix Island, at the mouth of the St. Croix river. Samuel de Champlain, the geographer of the expedition, explored the Maine coast, ascended the Penobscot and Kennebec rivers and discovered and named Mount Desert Island, on which Bar Harbor is now located. Bitter cold and scurvy reduced the St. Croix colony to less than one-half its original size by spring, when it was decided to relocate at Port Royal (now Annapolis Royal, Nova Scotia). In 1605 George Weymouth explored the St. George river area, captured five Indians and carried them to England, where three of them lived for a time in the family of Sir Ferdinando Gorges, who was to become the leader in founding Maine. In 1607 the Plymouth company, of which Gorges was a member, sent out a colony, numbering 120 persons, under the direction of George Popham and Raleigh Gilbert. The colony was established at the mouth of the Kennebec river in August, but because of insufficient supplies about three-fifths of the company returned to England in December. Popham died during the winter and Gilbert assumed command. The next spring the news of the death of one of the colony's chief sponsors and a rich inheritance for Gilbert, together with the hardships of the winter, caused the colonists to abandon the settlement and return to England. In 1613 the French Jesuits Pierre Biard and Edmond Masse began the construction of a mission station on Mount Desert Island, but the station was destroyed by Sir Samuel Argall, acting under the instructions of the English at Jamestown, Va.

Proprietary Period and Massachusetts Ownership.—In 1620 the Council for New England, successor to the Plymouth company, obtained a grant of the country between 40° and 48° N., extending from sea to sea; and two years later Gorges and John Mason received the land between the Merrimack and Kennebec rivers under the name Province of Maine. In 1629 the territory was divided; with Gorges taking the portion between the Piscataqua and Kennebec rivers. In the early 1630s numerous land grants were made in the vicinity of Kittery, Wells, York, Saco, Scarborough and Falmouth (Portland), and permanent settlements were established. In 1635 the Council for New England surrendered its charter, but Gorges kept the land which had been granted to him, calling it New Somersetshire. In 1639 he procured a royal charter investing him with feudal powers. His charter, however, conflicted with other grants by the Council for New England; his authority was contested especially by George Cleeve, whose Lygonia patent issued by the council extended along the

coast from the Kennebunk to the Kennebec.

Simultaneously, Massachusetts, fearing the royal authority in Maine, reinterpreted its charter so as to make its northern boundary an east-west line 3 mi. N. of the source of the Merrimack river. This meant that Massachusetts laid claim to land as far east as Casco bay, or almost the whole of settled Maine. Massachusetts received the allegiance of Maine towns between 1652 and 1658. In 1677 Massachusetts purchased the claims of the Gorges family for £1,250 and held the province as a proprietor until 1691, when, by the new Massachusetts charter, Maine was extended to the St. Croix river and made an integral part of Massachusetts.

Maine was subjected to the rigours of six wars (known collectively as the Indian Wars) between 1675 and 1763. In four of these the French were active allies of the Maine Indians against the English. During the first three wars the English were virtually driven from Maine, but the tide turned permanently in their favour after the treaty of Utrecht in 1713.

During the American Revolutionary War, in 1775, the town of Falmouth (Portland) was burned as a reprisal for its defiance of British law. Benedict Arnold marched through Maine on his expedition to Quebec (1775), and the first naval engagement (the battle of the "Margaretta") of the Revolutionary War occurred off Machias. An attempt by the Americans to recapture Castine, which the British had occupied in 1779, was a dismal failure. From 1807 to 1812 the embargo and nonintercourse laws were a severe blow to Maine's shipping industry, and Eastport, Belfast and Bangor were captured and eastern Maine was occupied by the British with only token resistance in the War of 1812.

Statehood.—Maine was generally well governed by Massachusetts, but geographical separation, a heavy debt, unequal representation in the legislature and different economic and political policies (Maine was largely Democratic and Massachusetts Federalist) created a desire for independence even before the close of the Revolutionary War. After the War of 1812 the independence movement gained momentum, and in 1816 Massachusetts authorized separation if a popular vote gave a majority of five to four for separation. As the vote was only 11,969 yeas to 10,347 nays, the advocates of separation were unsuccessful. A source of strong opposition to separation was removed in 1819 when congress rearranged the customs districts so that coasting vessels from Maine, as a separate state, would not have to enter and clear on every trip to or from Boston. Consequently, separation measures were carried by large majorities that year, and a constitution was framed by a convention that met in Portland in October. The constitution was ratified by town meetings in December and Maine applied for admission into the union. Because of the controversy then current in congress concerning the admission of Missouri as a slave state, Maine's admission became an important national issue. Finally by an act of March 15, 1820, Maine was admitted, its admission being a part of the Missouri Compromise (q.v.).

Boundary Dispute.—The northeast boundary of the state, which forms the northeast boundary of the United States, was long a matter of serious controversy between the United States and Great Britain. The treaty of 1783 ending the Revolutionary War identified the boundary in part as extending along the middle of the St. Croix river to its source, from there due north to certain highlands and along the highlands "to the north-westernmost head of Connecticut river." The dispute concerned just what the St. Croix river was and the location of its source and which highlands were to mark the boundary. The exact location of the St. Croix and its source was established by a commission provided for by the Jay treaty of 1794, but identifying the highlands proved to be a more difficult problem. Maine claimed that the highlands referred to overlooked the St. Lawrence river, but Great Britain contended that they were in the vicinity of Mars hill. The king of the Netherlands was chosen as arbitrator, and in 1831 he returned a decision unfavourable to Maine, causing the federal senate to withhold its assent. The disputed area thus became the scene of a disturbance known as the Aroostook War in 1838-39. Maine erected forts along the line it claimed, and the federal government prepared to resist British efforts to exercise exclusive jurisdiction. War seemed inevitable until Gen. Winfield Scott,

who had been sent to take command on the Maine frontier, was able to arrange a truce whereby both sides withdrew their armed forces in favour of a civilian posse. Three years later the Webster-Ashburton treaty was effected, whereby Maine and Great Britain divided the disputed territory virtually in half.

19th-Century Politics.—From 1820 until 1854 Maine was classed as a Democratic state, although Whig governors were elected in 1837, 1840, 1852 and 1853. With its prohibitory laws of 1846 and 1851, Maine pioneered in regulating the liquor business. As a result of the prohibition and slavery questions there was a party disintegration between 1850 and 1855, followed by the supremacy of the Republican party from 1856 to 1878. In the latter year no gubernatorial candidate received a majority of the votes as required by the constitution and consequently a Democratic-Greenback fusion in the legislature declared the Democratic candidate, Alonzo Garcelon (1813–1906), governor. The electorate again failing to select a governor the following year (state elections were annual until 1897 when they were made biennial), Governor Garcelon and his council counted out Republicans and replaced them with fusion candidates in the legislature. On Jan. 3, 1880, the supreme court declared the governor and council in error in counting in a fusion majority, but on Jan. 7 the governor swore in a legislature with 78 fusion and only two Republican members; the governor's term having expired, the president of the senate, James D. Lamson, became governor ex-officio. On Jan. 12 the Republicans, whose organized legislature was declared legal by the supreme court, seized the legislative chambers and chose as governor Daniel F. Davis. Former Governor Joshua L. Chamberlain was largely responsible for the peaceful solution of the difficulty which had had the state on the edge of civil war for a number of weeks, and ultimately Republican legislators and a Republican governor took office. In 1880 the Democrats and Greenbackers united and elected their candidate, but after 1882 Maine was strongly Republican until 1910.

Modern Times.—In 1910 the Democrats elected a governor and also in 1914, but Republicans again dominated politics otherwise until the 1930s. Louis Brann, Democrat, was elected in 1932 and re-elected in 1934, but Franklin D. Roosevelt failed to carry the state. In 1933 Maine voted for the repeal of the 18th amendment (prohibition) and in 1934 repealed its own prohibition statute. The high hopes held for the Passamaquoddy bay hydro-electric project were dashed in 1936 when congress discontinued funds for it though President Roosevelt favoured it. In 1950 a Canadian-U.S. commission indicated that detailed study must be made before the project's revival as a joint undertaking would be possible. After World War II several army and navy airfields in Maine were closed, but construction of the huge Loring air base at Limestone was undertaken. The Presque Isle, Bangor and Brunswick air bases were reactivated in 1951 and became increasingly important in the national defense system. The principal ground station for the communications satellite Telstar I was completed near Andover in 1962 and took part in the exchange of telephone messages and television programs between the U.S. and Europe. The Andover station used a 177-ft.-long horn antenna, traveling wave tubes, lasers and a special feedback circuit to receive and amplify signals received from the satellite.

Maine's traditional Republicanism was shaken in 1954 when Democrat Edmund S. Muskie won the governorship; he easily won re-election in 1956, and in 1958 he became the state's first popularly elected Democratic U.S. senator. Adding to the Democratic trend was the election in 1956 of a Democratic congressman, Frank M. Coffin, who was re-elected in 1958 and joined by another Democratic congressman, James C. Oliver, to give the Democrats two of Maine's three seats in the house. Clinton A. Clauson, Democrat, won election that year as Maine's first four-year-term governor; on his death on Dec. 30, 1959, however, he was succeeded by the Republican president of the state senate, John H. Reed. In 1960 Reed defeated Coffin for the governorship. He was elected to a full term in 1962, but was upset by Democrat Kenneth M. Curtis in 1966, when Republican Sen. Margaret Chase Smith was elected to her fourth term. In presidential elections Maine voted Democratic in 1964 for the first time since 1912.

GOVERNMENT

Maine was long noted as the only state to hold elections in September, but a constitutional amendment approved by the voters in 1957 moved its election day to the November date of other states, effective in 1960. The state has had only one constitution ratified in Dec. 1819. It admits of amendment by a two-thirds vote of both houses of the legislature, followed by a majority vote of the electorate at the next election; or, as provided by an amendment adopted in 1875, the legislature may by a two-thirds vote of each house summon a constitutional convention. Among the most important amendments adopted have been those which granted the franchise to the Indians, authorized a \$20,000,000 bond issue for a state industrial mortgage program, changed the election date from September to November and established the four-year term for governor.

Executive.—The governor is the only executive officer of the state elected by popular vote. There is no lieutenant governor; the president of the senate succeeding to the office of governor in case of a vacancy. There is also a council of seven members elected by the legislature (not more than one from any one senatorial district), whose sole function is to advise the governor. His power of appointment is unusually extensive, but the advice and consent of the council (instead of that of the senate as in other states) are required for his appointments. He appoints judges, medical examiners and notaries public, besides all other civil and military officers for whose appointment neither the constitution nor the laws provide otherwise. His removal power extends even to the locally elected sheriffs and county attorneys. Besides the seven members of the council, the secretary of state, the treasurer, the attorney general, the commissioner of agriculture and the auditor are elected by the legislature.

Legislative.—The legislature meets on the first Wednesday in January in odd-numbered years. It is composed of a senate of 34 members and a house of representatives of 151 members. Members of each house are elected for terms of two years, senators from counties roughly on the basis of one for each 30,000 inhabitants, and representatives approximately according to the population of towns and cities, with a maximum of seven for any one municipality. In 1908 a constitutional amendment provided for referendum and initiative by the people.

Judiciary.—At the head of the judicial branch is the supreme judicial court, which consists of a chief justice and five associate justices appointed by the governor and council for terms of seven years. The court's chief function is to hear appeals on points of law, but it renders advisory opinions when requested by the governor, council or either branch of the legislature. Below the supreme court is a seven-member superior court, whose members are also appointed for seven-year terms. Each judge goes on circuit in various counties as assigned by the chief justice of the supreme court.

The superior courts are the only jury courts in Maine. They hear appeals from the local courts and hear the more important civil and criminal cases as courts of first instance. In 1961 legislation was adopted to replace part-time municipal and trial justice courts with full-time district courts.

Local Government.—The principal units of local government are the town (or township), the plantation, the county and the city. As in other parts of New England, the town or city is the most important of these. At the regular town meeting, ordinarily held in March, the electorate of the town assembles, decides what shall be done for the town during the ensuing year, elects officers to execute its decisions with limited discretion and votes money to meet the expenses. The principal officers are the selectmen (usually three), town clerk, assessors, collector, treasurer, school committee and road commissioner. Maine is the only state in the union that retains what is known as the organized plantation. This is a governmental unit organized from an unincorporated township having at least 200 inhabitants, and its principal officers are the moderator, clerk, three assessors, treasurer, collector, constable and school committee. The city-manager form of government was introduced in Maine in 1917 in the city of Auburn. The county is an intermediate organization between the state and the towns, to

assist chiefly in the administration of justice, especially in the custody of offenders. Its officers are three commissioners, a treasurer, a register of deeds, a judge of probate, a register of probate, a clerk of courts, a county attorney and a sheriff.

Finance.—Before 1912 the state constitution forbade the borrowing of money in excess of \$300,000, except for the suppression of a rebellion, for war purposes or for repelling an invasion. In that year an amendment to the constitution was adopted allowing the state to incur a debt not exceeding \$2,000,000 for state highway purposes. Between 1912 and 1935, 12 amendments dealt with state debt and bond issues, gradually increasing the debt limit. An amendment adopted in 1950 removed all debt limitations and permitted bonds to be issued at the discretion of the legislature, by a two-thirds vote of each house, subject to popular referendum.

In order of importance, the chief sources of state funds in the second half of the 20th century were federal grants, gasoline tax, liquor, registrations and drivers' licences, general property tax, cigarette and tobacco taxes and public utility and insurance company taxes. These accounted for about three-fourths of the operating funds. Revenue was more than \$100,000,000 annually, about 20% of which was from federal grants. Lacking an income tax or general sales tax, the state had a narrow tax base until 1951, when the legislature enacted a general 2% sales tax (exempting, however, food). In 1957 the rate was increased to 3%. With the additional revenue thus provided, the state was able to increase substantially its services, particularly in the fields of education and health and welfare. At that time, expenditures were about \$110,000,000 annually. The bonded debt was about \$40,000,000. The major expenditures were for highways, health and hospitals, education, and public welfare. Total expenditures nearly doubled between 1950 and 1960, but revenues maintained a similar pace. Per capita income rose from \$1,188 in 1950, nearly \$300 below the national average, to \$1,843 in 1961.

POPULATION

The census of 1820, the year Maine entered the union, revealed that the state had a population of 298,335. This placed it 11th among the 27 states and territories that then composed the union. The population was classified as a little more than 97% rural. The decade between the censuses of 1790 and 1800 was the period of most rapid growth—the population showed an increase of 57.2% in 1800 over that of 1790. At mid-19th century the state had a population of 583,169 (86% rural) and was 16th in population among the 37 states and territories. During the decade between 1860 and 1870 Maine's population declined by about 0.2%. In 1900 the population was 649,466 (66% rural) and ranked the

state 31st in the union. The 1950 population figure was 913,774 (35th among the states), 51.7% of which was urban. In 1960 Maine had a population of 969,265, an increase of 55,491 or 6.1% over 1950. The total urban population for 1960 was 497,114 or 51.3% of the total. The standard metropolitan statistical area of Portland had a population of 120,655 in 1960, an increase of 713 over 1950. The population per square mile in 1960 was 29.2, as compared with 49.6 for the United States as a whole.

Distribution by colour and nativity in 1960 was as follows: 93.2% native white; 6.1% foreign-born white; and 0.6% non-white. Of the foreign-born white population, 72.1% were Canadians, 6.7% were born in Great Britain and 3.6% in Ireland. Of the total population, 10.8% was 65 years old or over. Of the population 14 years old and over, 50.9% was in the labour force.

EDUCATION

Public Schools.—The first school in Maine was a mission established in 1696 by Father Sebastian Rasle on the Kennebec river. Other Jesuit missions were shortly afterward established at Passamaquoddy and at Indian Island. The first town school was established at York in 1701. Characteristic of the early days of education in Maine were the "moving schools," which traveled from place to place, remaining only a few weeks in one location. Greater organization was introduced in 1789 when Massachusetts, of which Maine was then a part, adopted a law requiring liberal instruction for all children and college training for all teachers. When Maine became a separate state in 1820, its educational system was patterned after that of Massachusetts. In 1828 the income from certain state lands was designated a public-school fund. Legislation passed in 1873 provided for the creation of free public high schools; education was made mandatory in 1875.

The state department of education is administered by a commissioner selected by an unpaid state board of education, consisting of ten members serving five-year overlapping terms. The department supervises the distribution of state subsidies to local areas on the basis of complex legislative formulas, designed to secure uniform minimum standards and to aid the less wealthy communities. The department exerts considerable control over school-building design, curriculums, teaching methods and teacher training, certification and placement. It is also responsible for education in the unorganized townships where there is no local government. Still further, it groups towns and small cities into unions which are administered by locally chosen superintendents of schools. Towns and cities retain considerable local autonomy in school affairs. A sizable quantity of school-building districts were created by special legislative acts to allow municipalities to circumvent the constitutional debt limit (usually 5% of the assessed valuation).

In 1957 the legislature passed the Sinclair bill, designed to encourage the formation of school districts and the consolidation of small high schools. At that time Maine had more than 125 high schools with fewer than 100 pupils.

Children between the ages of 7 and 15 are required to attend school. The free public elementary and secondary schools are supplemented by numerous parochial schools and more than 50 private schools and academies. At mid-20th century Maine was spending about \$222 annually per pupil, or about \$70 less than the national average.

Higher Education.—The state department of education (see above) administers the state teachers' colleges, at Gorham, Farmington, Fort Kent, Machias (Washington State) and Presque Isle (Aroostook State); and a trade school, the Vocational Technical institute, at South Portland. The state also operates a maritime academy at Castine.

Chief among the state-controlled institutions of higher learning is the University of Maine, at Orono, established in 1865 as the State College of Agriculture and the Mechanic Arts; the name was changed to University of Maine in 1897. The university is composed of schools and colleges of arts and sciences, agriculture, home economics, technology and education, forestry, nursing, and physical education and athletics. The school of law is in Portland. The university also has a division of graduate study; co-operative

extension service; agricultural experiment station; technology experiment station; and department of industrial co-operation. In 1957 the university absorbed the Portland junior college, after which the latter was operated as a branch under the name of the University of Maine in Portland.

Among the private institutions of higher learning is Bowdoin college, founded in 1794 at Brunswick (*q.v.*). Other colleges are Bates college (Lewiston, nonsectarian, 1864) and Colby college (Waterville, nonsectarian, 1813).

HEALTH AND WELFARE

The state's welfare activities were co-ordinated in 1931 by an act establishing the department of health and welfare. The department was composed of three bureaus, health, welfare and institutional service, having authority over the state's welfare program. In 1939 the legislature removed control of state institutions from health and welfare to a new department of institutional service.

The penal and reformatory institutions consist of the state prison, at Thomaston; the reformatory for men, at South Windham; the reformatory for women, at Skowhegan; the state (reform) school for boys, at South Portland; and the state (reform) school for girls, at Hallowell; the state schools are not places of punishment, but reformatories for delinquent boys from 8 to 16 years of age and girls from 6 to 16 years of age who have been committed by the courts for violations of law, or, in the case of girls, who, by force of circumstances or association, are "in manifest danger of becoming outcasts of society." The inmates in these schools get instruction in various trades and occupations so as to be able to earn a living when discharged.

Paupers formerly were cared for chiefly by towns and cities, those wholly dependent being placed in almshouses and those only partially dependent receiving aid in their homes. Federal-state funds for old-age assistance, aid to dependent children, aid to the blind and aid to the permanently and totally disabled are administered by the department of health and welfare. Unemployment compensation is administered by an employment security commission of three members.

The mental and charitable institutions maintained by the state are: the Augusta State hospital, at Augusta; Bangor State hospital, at Bangor; Central Maine sanatorium, at Fairfield; Pineland Hospital and Training School for the Feeble-minded, at West Pownal; Military and Naval Children's home, at Bath; and the Maine School for the Deaf, at Portland.

THE ECONOMY

Agriculture.—Agriculture is less important than it once was in Maine, the number of farms having declined from around 50,000 at the time of World War I to about 18,000 in the second half of the 20th century. Maine ranks first among the states in potato production, with Aroostook county as the leading producing centre. Production usually amounts to more than 60,000,000 bu. annually. To avoid a one-crop economy Aroostook county has begun raising peas, oats and beef cattle. Other important state crops are corn, barley, hay, beans, McIntosh apples and blueberries. Market gardening is important in the area around Portland. Dairying has long rivaled potatoes in importance. The most significant agricultural development after World War II was the raising of poultry, especially broilers. In ten years the number of broilers raised multiplied more than five times, to more than 50,000,000. Belfast is the centre of the industry.

Industry.—The construction of wooden ships was a principal industry in Maine until the middle of the 19th century, with some building of wooden (principally "downeasters" and schooners) and steel ships continuing, especially during World Wars I and II. Bath remains the chief centre of this activity. Cotton, woolen and paper mills, built in large numbers in the 19th century, were located on rivers to take advantage of the abundant water power. Sawmills were numerous from early colonial days. Later a variety of woodworking industries was established. After World War I there began a decline in textile manufacturing, which continued after World War II. Paper mills, shoe factories and food proc-

essing plants replaced the textile factories. The paper and textile industries were the leaders in the value of their products, but the leather products industry, especially shoes, employed the largest number of persons.

Minerals.—Maine formerly produced bricks, lime, granite and slate in sizable quantities, but output of these materials has dwindled. The state's principal mineral products in order of value are cement (New England's only cement plant is located at Thomaston), sand and gravel, stone, sheet mica, feldspar (about 25% of all the feldspar produced in the U.S.) and beryllium ore concentrates, with an average annual value in excess of \$12,000,000. Maine, however, produces less than 1% of the total mineral output of the U.S.

Fisheries.—Fishing is an important coastal industry, affording employment to about 10% of the state's population. The catching and packing of young herring under the trade name of sardines represents the largest annual catch but is greatly exceeded in value by the lobster catch. Other fish of commercial importance include cod, haddock, hake, pollack, mackerel, ocean perch, alewives and flounders. Clams, sea scallops and crabs are also abundant in Maine waters. A rapidly growing activity is the collection of bloodworms and sandworms for bait. Average annual landings at Maine ports in the second half of the 20th century totaled about 300,000,000 lb. valued at approximately \$20,000,000. Lobsters alone accounted for about 55% of these revenues.

Forestry.—More than four-fifths of the land area of Maine is forested (after Alaska the largest per capita acreage in the nation), and more than one-half of the land area is unorganized territory, with no local government and few permanent inhabitants. A forest district tax on timberlands finances fire protection and other services performed by the Maine forest service.

Lumbering has always been Maine's chief industry. In colonial days Maine pine trees were the chief source of masts for the British navy. In the 19th century the forests sustained the many shipyards, and Maine was long the leading producer of wooden ships in the United States. In the 20th century the same forests supplied pulpwood for the paper mills and lumber for the building trades. The annual production of pulpwood in the second half of the 20th century was more than 1,900,000 cords and that of lumber exceeded 500,000,000 bd.ft. Hardwoods, such as maple, beech and birch, were also widely used to make plywood, spools, dowels, toothpicks, skis, furniture, toys and novelties. Wood-using industries employed more than one-third of the wage earners of the state.

The Allagash region of northern Maine has been the major source of pulpwood. In the 1960s the establishment of an Allagash national recreation area was proposed to preserve about 300,000 ac. of wilderness including more than 60 lakes and 360 mi. of rivers and streams.

Transportation and Communications.—The southwestern part of the state, where the manufacturing, quarrying and much of the older agricultural district are located, always has had satisfactory means of transportation either by water or rail. The first international railroad in North America, the Atlantic and St. Lawrence (now a part of the Canadian National system), connected Portland and Montreal in 1853. During the American Civil War the chief railroad system in Maine was begun when the Maine Central was formed out of two short-line railroads connecting Lewiston and Bangor. It was not until the last decade of the 19th century that the forests, farmlands and summer resorts of Aroostook county were reached by rail. In the second half of the 20th century, following considerable contraction, particularly in the less populous areas, the total railway mileage was slightly less than 2,000. Formerly there were five narrow gauge lines (two feet between the rails) and numerous electric lines operating in the state, but they have all become defunct. Many branch lines have been abandoned and passenger service on the Maine Central ceased in 1960.

Maine's coast line has many excellent harbours. The Kennebec river is navigable for coast vessels to Augusta, and the Penobscot to Bangor. For decades steamboats regularly plied between Maine ports and Boston, New York and several Canadian ports.

but none have operated since just before World War II. In 1956 the Canadian National railways instituted a daily ferry service between Bar Harbor, on Mount Desert Island, and Yarmouth, Nova Scotia. This service proved attractive to the tourists who annually visit Mount Desert Island and Acadia National park.

Maine is connected with the other states by commercial airlines. Plane, auto and truck transportation have all but eliminated rail passenger service and drastically reduced rail freight traffic. Modern highways have been built in many parts of the state, including a turnpike running from the state capital, Augusta, to the New Hampshire line. Highways totaled more than 20,500 mi.

See also references under "Maine" in the Index.

BIBLIOGRAPHY.—There is no satisfactory complete history of Maine. *Maine, A History*, 2 vol. (1919), ed. by Louis C. Hatch et al., treats the state's history to the date of its publication. Bibliographical aids are: Joseph Williamson, *Bibliography of the State of Maine From the Earliest Period to 1891* (1896); H. W. Bryant, *Check List of Maine Town Histories* (1902-04); A. J. Huston, *Check List of Maine Local Histories* (1915); Elizabeth Ring (ed.), *A Reference List of Manuscripts Relating to the History of Maine*, 3 vol. (1938-41). See also Henry S. Burrage, *The Beginnings of Colonial Maine, 1602-58* (1914); Gorges and the Grant of the Province of Maine, 1622 (1923); H. M. Sylvester, *Maine Pioneer Settlements*, 5 vol. (1909); J. P. For population etc., see also U.S. *Census Reports*; *Minerals Yearbook*. For description, see L. L. Hubbard, *Woods and Lakes of Maine* (1883); W. Emerson, *When North Winds Blow* (1922).

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition.

(R. M. Y.)

MAINE DE BIRAN, MARIE FRANÇOIS PIERRE GONTHIER (1766-1824), French philosopher, was born at Bergerac on Nov. 29, 1766. The name Maine he assumed from an estate called Le Maine which belonged to his father. Maine de Biran entered the king's lifeguards and defended Louis XVI at Versailles on Oct. 5 and 6, 1789. He then retired to his estate at Grateloup, near Bergerac, and pursued his studies in mathematics and philosophy until, after the fall of Robespierre, he entered public life as an administrator in the *département* of the Dordogne. He became a member of the Corps Législatif in 1809 and was among those who expressed public opposition to Napoleon in 1813. After the Restoration he became treasurer to the chamber of deputies. He died in Paris on July 16, 1824.

Maine de Biran first became known in the intellectual world as one of the *Ideologues*. These philosophers developed the anti-metaphysical and empiricist aspects of Locke's philosophy in the manner of Condillac; and Maine de Biran's philosophical importance consists in his gradual and detailed discovery of the inadequacies of this point of view. His diary, in which he commented on his administrative and political activities as well as on his philosophical reading, throws valuable light on the thoughts and struggles of a diffident philosopher forced to play a decisive part in politics. Both as philosopher and as diarist his interest is in the inner life of man.

His first important philosophical writing and one of the few published during his lifetime was *Influence de l'habitude sur la faculté de penser* (1802; Eng. trans. by M. D. Boehm, *The Influence of Habit on the Faculty of Thinking*, 1929). In it, developing an idea of Destutt de Tracy's, he stresses the role of the will in our perception of the physical world and argues that the result of becoming habituated on a being that possessed only sense-experience would be that it would lose consciousness altogether. These themes of the importance of the will and of the impossibility of analyzing the self entirely in terms of sensation and feeling were developed in later works. In his *Mémoire sur la décomposition de*

la pensée (1804), Maine de Biran criticizes Descartes for confusing the self considered as subject with the self considered as a substance in the natural world and is thus led to suppose that the methods appropriate to the study of nature are incapable of revealing the essence of selves or subjects. In his *Essai sur les fondements de la psychologie* (1812), Maine de Biran concluded that there is a "hyperorganic" element in the self, even though "my body and myself form a single being." In his *Nouveaux essais d'anthropologie* (1823-24) he describes the self as developing through an animal, purely sensitive phase (*vie animale*) to a human phase of will and freedom (*vie humaine*) and culminating in experiences which transcend humanity (*vie de l'esprit*).

BIBLIOGRAPHY.—The edition of Maine de Biran's works by P. Tisserand, 14 vol. (1920-49), is supplemented by those of his *Journal* by H. Gouhier, 3 vol. (1954-57), and of his *De l'aperception immédiate* by J. Echeverria (1963). See also V. Delbos, *Maine de Biran et son oeuvre philosophique* (1931); G. Le Roy, *L'Expérience de l'effort et de la grâce chez Maine de Biran* (1938); Gerhard Funke, *Maine de Biran: philosophisches und politisches Denken zwischen Ancien Régime und Bürgerkönigium in Frankreich* (1947); Henri Gouhier, *Les Conversions de Maine de Biran* (1947); A. Huxley, *Themes and Variations* (1950); A. Cresson, *Maine de Biran, sa vie, son oeuvre* (1950); P. Hallie, *Maine de Biran: Reformer of Empiricism* (1959). (H. B. A.)

MAINE-ET-LOIRE, an inland *département* of western France, formed in 1790 for the most part from the southern portion of the ancient province of Anjou (q.v.), and bounded north by the *départements* of Mayenne and Sarthe, east by Indre-et-Loire, southeast by Vienne, south by Deux-Sèvres, southwest by Vendée and west by Loire-Atlantique. Area 2,787 sq.mi. Pop. (1962) 556,272. The *département* is traversed from east to west by the broad valley of the Loire river, which in the centre receives an important right-bank tributary, the Maine, formed from the confluence above Angers of the Mayenne, Sarthe and Loir. The western part of the *département*, on the old schist rocks of the Armorican massif, is rather hilly, pastoral country, concerned mainly with livestock farming. This *bocage* of fragmentary woodlands and farmland that consists of a patchwork of small fields enclosed by quickset hedges contrasts strikingly with the open grain lands (*plaines*) of the east, on platforms of younger calcareous rocks trenched by the alluvial valleys of the Loire, Loir and Sarthe. The Loire valley, known there as the Val d'Anjou, is a strip of rich meadows, market gardens, orchards and vineyards. Hemp was formerly widely grown, but has given way to other, more profitable crops. The rainfall is moderate and the climate notably mild in winter, when mists are a feature of the weather. Delicate plants flourish out of doors and vegetables can be produced very early. The north of the *département* lies on the northern limit of viticulture, however, and vineyards are found chiefly in the Loire valley and in the south of the *département* astride its left-bank tributary, the Layon, where the schist soils give the wine a distinctive character. The warm weather that persists into late autumn is responsible for the special degree of maturation of Angevin wines. Saumur is famous for its sparkling white wine. In the western and northern parts of the *département* large quantities of cider apples are produced. The slates of the Armorican massif are quarried in places, especially at Trélazé, and deposits of high-grade iron ore that occur in a belt across the north of the *département* are worked in the vicinity of Segré. Electrical engineering developed after World War II at Angers, but there is generally little manufacturing and the *département* is almost entirely agricultural, the towns being essentially markets and rural service centres. Such are Angers, Saumur, Segré and Cholet, the centres of the four *arrondissements* into which the *département* is divided.

Angers (pop. [1962] 109,614), the largest town and *préfecture* and the ancient capital of Anjou, situated at an important junction of routes on the Maine river 5 mi. above its confluence with the Loire, is also the seat of a bishopric that is coextensive with the *département*. It has a court of appeal, but for educational administration the *département* comes under Rennes. The great 13th-century castle and the cathedral, dominating the town, together with other old buildings and museums that house fine collections of tapestries, paintings and other art objects, make Angers one of the most attractive old towns of France. The castle at Saumur and the abbey at Fontevault-l'Abbaye, with a fine Romanesque

church where the first Plantagenets were buried, are also especially noteworthy. The interesting old town of Les Ponts-de-Cé, built partly on islands in the Loire, with seven bridges, provided the only bridge crossing of the river between Nantes and Saumur until after the French Revolution. Although the Loire and Mayenne, and to a lesser degree the Sarthe, are navigable, they no longer carry much traffic.

(AR. E. S.)

MAINE RIVER, France, is a right-bank tributary of the Loire (q.v.) which it enters at La Pointe below Angers. The Maine itself (7 mi. long), located in Maine-et-Loire *département*, is formed from the confluence of the Mayenne, Sarthe and Loir rivers. The Mayenne, rising in the hills of Normandy, flows south past Laval through the hilly pastoral country of the easternmost part of the crystalline Armorican massif. The Sarthe and its tributary the Huisne, which joins it at Le Mans, rise in the hills of the Perche. Before joining the Mayenne, the Sarthe receives the Loir, flowing westward from the margins of the limestone platform of Beauce. The dry, sandy platforms of Maine, which the Sarthe and Loir traverse, are far from fertile and carry much woodland, but the broad river valleys, with their alluvial floors, are exceptions, with strips of rich cultivation, including orchards and vineyards at their northern limit. Below Angers, the Maine valley enters the wide alluvial trench of the Loire, there known as the Val d'Anjou. The navigable waterway of the lower Loire is continued by the Maine, and the Mayenne is navigable by small craft as far as Brives and the Sarthe less satisfactorily to Le Mans.

(AR. E. S.)

MAINPURI, a town and district in the Agra division of Uttar Pradesh, India. The town lies 68 mi. E. of Agra city and consists of two distinct parts: Mainpuri proper and Ganj or Mukhamganj. Pop. (1961) 33,610. The main places of interest are the raja's palace or *Garhi*, the mission buildings including a high school, and the Lanegunj market. The town is well known for its carved wooden articles inlaid with brass wire and for chewing-tobacco. Its industries include cotton ginning and electric-lamp and glass works. The Agra branch of the Grand Trunk road passes through the town, which is also served by the Northern railway.

MAINPURI DISTRICT lies in the Ganges-Jumna doab. Pop. (1961) 1,180,894; area 1,680 sq.mi. It consists of an almost unbroken plain wooded throughout with mango groves; isolated clumps of babul trees occasionally relieve the bareness of its usar (saline) plains. On the southwestern boundary the Jumna flows in a deep alluvial bed, in some places sweeping under high banks and elsewhere leaving a strip of fertile soil between the river and the upland plain. The district is watered by the Upper and Lower Ganges canal. Its main crops are wheat, gram, barley and rice.

Mainpuri formed part of the great kingdom of Kannauj (q.v.), and after the fall of that state was divided into a number of petty principalities. It fell to the Moguls on Babur's invasion in 1526, passed in the late 18th century to the Marathas, and later became a part of Oudh province. When this part of the country was ceded to the British in 1801, Mainpuri town became the headquarters of the extensive district of Etawah, which was in 1856 reduced by the formation of Etah and Mainpuri into separate collectorates.

MAINTAINED PRICE: see FAIR TRADE LAWS.

MAINTENON, FRANÇOISE D'AUBIGNÉ, MARQUISE DE (1635-1719), the second and secret wife of Louis XIV of France, was born at Niort in Poitou, where her father, Constant d'Aubigné, the disreputable son of the great Huguenot soldier and poet Théodore Agrippa d'Aubigné, was a prisoner of state under relaxed surveillance; her mother, Jeanne de Cardilhac, whom Constant had married in Dec. 1627 (during the first months of his detention) had already had three other children by him. Baptized as a Catholic on Nov. 28, 1635, Françoise was brought up as a Huguenot by her aunt, Mme de Villette (Louise Artémise d'Aubigné), till Constant's release (1642). Constant was in 1645 appointed governor of the West Indian island of Marie Galante, but found nothing to do there and installed his family on Martinique before returning to France; he died at Orange on June 17, 1647. When Françoise was brought back to France, Mme de Villette took charge of her again; but soon the comtesse de Neuillant

(Louise Tiraqueau) obtained the custody of the child and proceeded to reconvert her to Catholicism. In April or May 1652 Françoise, by this time probably an orphan, was married to the deformed and invalid writer Paul Scarron (q.v.).

How Mme Scarron lived with her husband's mixed entourage in Paris is a matter of some uncertainty. Later her enemies alleged that she found lovers among the gentlemen who visited the impecunious household—in particular the marquis de Villarceaux (Louis de Mornay). Yet on Scarron's death (Oct. 1660) she would have been almost destitute if certain ladies had not induced the queen mother, Anne of Austria, to allow her an annual pension of 2,000 livres, which enabled her to live decently.

Through her connection with noble ladies the widow Scarron was introduced to the marquise de Montespan (q.v.); and when the latter began to have children by Louis XIV she chose the widow as their governess (1669). At first these births were kept secret, and Mme Scarron conceived a deep affection for her clandestine charges, especially for the eldest son, later duc du Maine (q.v.). At the end of 1673, however, the children were legitimated, and in 1674 Mme Scarron appeared publicly with them at Versailles. In the spring of 1675 she bought the lordship of Maintenon, near Chartres.

The interest that Louis XIV began to take in the beautiful and intelligent widow (nearly three years his senior) soon excited Mme de Montespan's jealousy, and relations between the two women became strained. Maintenon was raised to a marquise in 1678, and Mme de Maintenon was appointed lady-in-waiting to the dauphine (Marie Anne Christine of Bavaria) in 1680. When Mme de Montespan fell definitively from favour after the Affair of the Poisons (q.v.), Mme de Maintenon was left in undisputed command of the king's affections; but she was devoutly anxious to avoid the scandals that his previous liaisons had provoked. The queen, Marie Thérèse, was delighted at the consideration with which she was now treated.

The queen died in Mme de Maintenon's arms on July 30, 1683. At a date that is still controversial, Louis XIV secretly married Mme de Maintenon. For the date, modern conjectures are divided between Oct. 1683 and April-May 1697.

The influence of Mme de Maintenon from the 1680s to Louis XIV's death was considerable in so far as she was habitually consulted by the king and also by his ministers, who always preferred to have her on their side; but while her views counted for much in matters of detail and, especially, in matters concerned with the domestic life of the royal household, they were not supreme in public affairs. A pious Catholic, she was largely responsible for the graver atmosphere at court after the licence of earlier years; and she was an assiduous converter of Huguenots, though she cannot be blamed for the savageries accompanying the revocation of the edict of Nantes (1685). The duc de Saint-Simon, whose portrait of "the hag" in his *Mémoires* has done much to blacken her reputation, regarded her as an upstart hypocrite in league with the Jesuits for the ruin of the Jansenists, the Quietists and Fénelon; but he hated her chiefly for promoting the elevation of her former pupils, the royal bastards. During the War of the Spanish Succession she maintained an intimate political correspondence with the princesse des Ursins (q.v.).

Deeply interested in Catholic education and mindful of her own past, Mme de Maintenon already in 1681 sponsored a home for poor girls at Rueil, which the king transferred to Noisy in 1684; her great achievement was the founding of an institution for poor girls of the nobility at St. Cyr, endowed by the king in 1686.

Louis XIV died on Sept. 1, 1715. Mme de Maintenon then retired to seclusion at St. Cyr. The regent Orléans continued her pension of 48,000 livres. She died at St. Cyr on April 15, 1719. There are editions of her letters by T. Lavallée (1856 and 1865-66) and by M. Langlois (1935-39).

Louis XIV et Madame de Maintenon (1958).

MAINZ (French MAYENCE), one of the oldest cities of Germany and a port on the Rhine river, which after partition of the nation following World War II became (1950) the capital of the Land (state) of Rhineland-Palatinate, Federal Republic of Germany. It lies on the left bank of the Rhine, opposite the junction of that river and the Main in the Rhenish wine-growing area. At the intersection of two federal highways (*Bundesstrassen*), Mainz is also a railway junction and is about 30 km. (18½ mi.) S.W. of the Rhine-Main international airport (near Frankfurt am Main). Including suburbs on the right bank of the Rhine, the city had a population of 158,533 in 1939; excluding the right-bank communities, which were later separated from Mainz, the population was 75,020 in 1946. Pop. (1961) 134,375.

Mainz was a pre-Roman settlement. Its strategic importance was early recognized by the Romans, who in the 1st century A.C. established a military camp that became known as Maguntiacum or Mogontiacum. A town gradually arose round the camp, which became the capital of Germania Superior. In about 451 the Romans abandoned the Rhine area. Mainz, already destroyed by Alamanni in 368 and by Vandals and Slavs in 406, was left unprotected against the mass migrations, and first found peace again under Frankish rule. In the 6th century, under Bishop Sidonius, a new Mainz arose, which in 747, under St. Boniface, became the ecclesiastical centre of Germany, and later (c. 780) an archbishopric. Charlemagne, who had a palace in the neighbourhood, gave privileges to Mainz, which grew rapidly in wealth and importance. In 1118 it attained certain rights of self-government and in 1244 it became a free city. In 1254, known as "Golden Mainz," it became the centre of a powerful league of Rhenish towns. But a decline in its commercial prosperity soon followed.

Mainz is noted for its association in the 15th century with Johann Gutenberg (q.v.) and the development of printing. In 1462 there was warfare between two rival archbishops. The citizens espoused the losing cause and were deprived of their privileges; many of them were driven into exile and thus carried into other places knowledge of the art of printing.

During the Thirty Years' War (1618-48), Mainz was occupied by Swedish and French troops. The French again occupied the fortress in 1792, when a small group of citizens, members of a Jacobin club who welcomed the ideas of the French Revolution, collaborated with them. After a long siege and much damage, Mainz was handed over to Prussian and Austrian forces in 1793. It was ceded to France by the treaty of Campo Formio in 1797 and again by the treaty of Lunéville in 1801. In 1814 Mainz was restored to Germany, and in 1816 it was given to the grand duke of Hesse. It was a fortress of the German confederation and later of the Reich. After World Wars I and II, Mainz was occupied by French troops. About 80% of the city was destroyed during World War II; however, reconstruction was rapid and extensive.

Roman remains include the rests of pillars of an aqueduct (the so-called Roman stones) and the Eichelstein (the sole of a monument believed to have been erected by the Roman legions in honour of the general Nero Claudius Drusus). Relics are housed in the Central Roman-Germanic museum.

St. Martin's cathedral towers over the city. Originally erected under Archbishop Willigis (975-1009), it is a Romanesque edifice that in the course of the centuries acquired additions of nearly every existing style. It was burned repeatedly and was continually rebuilt. Henry II, Conrad II and Frederick II were anointed and crowned emperor in the cathedral. Other noteworthy churches include St. Ignatius (18th century), St. Stephen, built 1257-1328 and restored in 1857, and St. Peter (18th century), all renovated after World War II. The University of Mainz (chartered in Nov. 1476, declined during the period of French dominance and was closed in 1816.

Mainz was revived as a university city in 1946 on the establishment of Johannes Gutenberg university, with which various faculties and special institutes are associated. The Max Planck Institute of Chemistry and the Academy of Sciences and Literature are there, and the Institute of European History was established in the building of the old university.

The Gutenberg monument, by Bertel Thorvaldsen and Charles Crozatier, was erected in 1837. The Gutenberg museum houses various exhibitions concerning printing and paper.

The archbishopric was one of the seven electorates of the Holy Roman empire, and became a powerful state during the middle ages, retaining some of its importance until its secularization in 1803. Its archbishop was president of the electoral college, arch-chancellor of the empire and primate of Germany. The lands of the electorate were on both banks of the Rhine; their area at the time of the French Revolution was about 3,200 sq.mi. The lands on the left bank were seized by France in 1801; at the secularization some of those on the right bank were given to Prussia and to Hesse, while others were formed into a grand duchy for Karl von Dalberg. The archbishopric itself was transferred to Regensburg, and Mainz became a bishopric only.

Trade and Industry.—Favoured by its site but hampered by its military importance and, until 1462, by the illiberal rule of its archbishops, the city developed its commerce in strong competition with Frankfurt am Main. Under Napoleon, Mainz suffered a sharp decline. Later it became the centre of the Rhenish wine traffic. Industries produce and export chemical and cosmetic products, sparkling wine, brandy, foods, luxury items, optical products and measuring instruments, glassware, paper, musical instruments, machinery and cement. Chief imports include pit coal, coke, grain and pig iron.

See also references under "Mainz" in the Index. (A. F. Pr.)

MAIORESCU, TITU (1840-1917), Rumanian philosopher, critic and statesman, who represents a western critical influence in modern Rumanian culture, was born at Craiova on Feb. 15, 1840. He studied at Vienna, Berlin and Paris, and taught for many years at Iași before becoming professor of philosophy at Bucharest university in 1884. He tried to reconcile the philosophical systems of Kant, Hegel and Schopenhauer, and translated Herbert Spencer's *A Plea for Liberty* in 1893. His sober, critical essays on culture and literature and his lifelong struggle against the absurdities of the Latinist school and against the new state's empty and false forms of civilization inaugurated a new era.

A leader and reformer of public opinion in the 1890s and after the turn of the century, he exercised a deep literary influence through the periodical *Convorbiri Literare* (1867) and through his teaching in the University of Bucharest. The literary society *Junimea*, created by him in Iași in 1863, developed into a conservative party to counteract the liberal party. He was prime minister and presided at the peace conference of Bucharest after the Balkan Wars (1913). He died at Bucharest on July 7, 1917.

See E. Lovinescu, *T. Maiorescu*, 2 vol. (1940). (G. Ns.)

MAIRET, JEAN (1604-1686), French dramatist, the fore-runner and rival of Corneille, was born in Besançon on May 10, 1604, and seems to have worked chiefly in Paris, where he secured important patrons, notably the duc de Montmorency and the comte de Belin. This enabled him to launch a series of plays which showed the growing taste of the public for regular drama. He started with pastorals, imitating the *Astrée* of Honoré d'Urfé (q.v.) in *Chryside et Arimant* (1625; ed. H. C. Lancaster, 1925) and more freely still in *Sylvie* (1626; ed. J. Marsan, 1905) and in *La Sylvanie ou la mort vive* (1630, ed. R. Otto, 1890). These, with a comedy, *Les Galanteries du duc d'Ossone* (1632), renewed conventional themes by dramatic skill and witty writing; it is known that Mairet and Paul Scarron used to practise *pointes* (witticisms) together. The preface to *Sylvanie* shows Mairet concerned to satisfy the public with the new "regular" Italian style of drama, observing rules of place and time and a new standard of verisimilitude and decency. He had even greater success in exploiting this regularity in tragedy: *Virginie* (1633), *Sophonisbe* (1634, ed. K. Vollmöller, 1888), *Le Marc-Antoine, ou la Cléopâtre* (1635), *Le grand et dernier Soliman* (1637). Finally he tried tragicomedy: *L'illustre Corsaire*, *Roland furieux*, *Athénaïs* and *Sidonie*, all acted between 1636 and 1641. After this he seems to have abandoned the theatre, for unknown reasons. In the quarrel over *Le Cid* he had bitterly opposed Corneille (q.v.), but there is no evidence that his pique continued. There are signs of political activity, culminating in the Fronde (q.v.), but nothing is known of

his last years. He died at Besançon on Jan. 31, 1686. His importance as an artisan of French classical drama is fully appreciated by modern critics. His characters, his verse, his situations were all used by contemporaries. Before Corneille, he brought to the stage the famous Cornelian figures Sophonisbe and Pulchérie, and he anticipated Racine's Roxane.

See H. C. Lancaster, *A History of French Dramatic Literature in the Seventeenth Century*, part 1, vol. 1 (1929); A. Adam, *Histoire de la littérature française au XVII^e siècle*, vol. 1 (1948). Dating of the plays has caused confusion because dates of publication and of acting vary; in this article dates of acting are given, and follow Adam.

(W. G. Mz.)

MAIRONIS, the pen name of the Lithuanian writer JONAS MAČIULIS-MAČULEVIČIUS (1862–1932), the most important poet at the time of the national awakening in Lithuania, who was born on Nov. 2, 1862, at Passandravys, Siluva. From 1883 to 1884 he studied literature at Kiev university, then theology at the seminary in Kaunas and at the Catholic academy, St. Petersburg. He became professor of moral theology at the seminary in Kaunas, and then at the Theological academy, St. Petersburg. In 1909 he was appointed rector of Kaunas seminary and, in 1922, became professor at Kaunas university. He died in Kaunas on June 28, 1932. In his lyrics, contained in *Pavasario balsai* (1895), satirical poetry, in *Rasėnių Magdė* (1909) and *Mūsų vargai* (1920), and poems, in *Jaujoji Lietuva* (1908), first published in 1895 as *Terp skausmų į garbę*, Maironis tries to awaken national feeling suppressed by foreign rulers. Importance of national consciousness is still more stressed in his dramatic trilogy idealizing ancient kings of Lithuania: *Kęstučio mirtis*, *Vytautas pas kryšiuočius* and *Vytautas Karalius* (1922–30). These won him great popularity in his country.

In the 20th century, Lithuanian literature tended toward both realism and neo-romanticism; Maironis turned to the latter, combining it with patriotic idealism. His verse is clear, direct, has harmonious form and is rhythmically versatile, and it was he who introduced syllabic metre into Lithuanian poetry.

See J. Tumas, *Jonas Mačiulis-Maironis* (1926). (J. A. A.)

MAISTRE, JOSEPH DE (1753–1821), French polemical writer and diplomat who, uprooted by the French Revolution and profoundly disturbed by its implications, became the first, as he remains the greatest, of the uncompromising exponents of the conservative tradition. He was born at Chambéry on April 1, 1753, the son of François Xavier de Maistre, president of the senate of Savoy. He studied with the Jesuits at Turin, entered the civil service of Savoy and became a member of the senate in 1787; he married Françoise de Morand in 1786. His intellectual formation was influenced by liberalism, freemasonry and illuminism, which seem at odds with his later opinions. His earliest writing was a *Mémoire au duc de Brunswick sur la Franc-Maçonnerie* (1781). On Sept. 22, 1792, Savoy was invaded by republican troops, resistance collapsed and the duchy was annexed. De Maistre left Chambéry for Geneva and lifelong exile; the shock impelled him to his vocation as a writer. He frequented Mme de Staël's salon at Coppet, and his *Considérations sur la France* (1796) was the outcome of controversy with Benjamin Constant, the French writer and politician. In 1793 he was established at Lausanne as official correspondent to Charles Emmanuel IV, king of Sardinia, who summoned him to Turin in 1797, made him chief magistrate of the Sardinian kingdom in 1799 and in 1802 appointed him envoy extraordinary and minister plenipotentiary at St. Petersburg, where he arrived on May 13, 1803. There he wrote all the works of his maturity, only one of which was published during this period: the *Essai sur le principe générateur des constitutions politiques* (1810). There he remained, separated from his wife and children, until June 1817, when he was recalled. In 1819 he was reappointed chief magistrate and made minister of state; he published *Du Pape* in that year. He died at Turin on Feb. 26, 1821.

Baudelaire asserted that De Maistre had taught him to think, and if the art of thinking is the relentless pursuit of logical consequences from an accepted premise, Joseph de Maistre is supremely a thinker. His personal experience of revolution compelled him to posit a spiritual absolutism, the sole principle of stability and continuity, from which all temporal order, including

monarchy, must be derived. He placed this absolutism in a sovereign pontiff, the pope, and his treatise *Du Pape*, with its pendant *De L'église gallicane*, examines all the corollaries of this conviction. But De Maistre's unflinching determination to follow his thought through to the end is displayed in his greatest, though unfinished, work, *Les Soirées de St. Petersbourg* (1821), with its acclaim of the public executioner as the guardian of social order, and in the *Lettres sur l'Inquisition espagnole*, with its apologia for the necessity of the Inquisition's punitive role. It is scarcely surprising to discover the animated virulence of his pages on Bacon, John Locke, Jean Jacques Rousseau and Voltaire—the rigorous prose rising to the apocalyptic visions of exile.

M. Cioran (1957).

(H. G. Wx.)

MAISTRE, (FRANÇOIS) XAVIER (JOSEPH MARIE) DE (1763–1852), French novelist and essay writer, younger brother of Joseph de Maistre, whose best-known work, *Voyage autour de ma chambre*, charmingly expresses the idea that happiness is found within oneself, was born at Chambéry on Nov. 8, 1763. He intended to be a painter but joined the Sardinian army and became an officer. When the French revolutionary armies overran Sardinia he left the country and in 1799 joined the Russian army in Switzerland, subsequently becoming one of Marshal Aleksandr Suvorov's aides. He lived in Moscow as a painter from 1800 until 1805 when, through his brother's influence, he became director of the naval library and museum. Returning to active service in 1810, he served in Persia and the Caucasus (where he was wounded), and became a major general in 1813, the year of his marriage. He left the army in 1816. He regarded painting and writing as mere pastimes, but his books are still remembered, especially *Voyage autour de ma chambre* (1795), written when he was temporarily confined to quarters as a young soldier. Still a model of fantasy and wit, it passed through many editions and translations and was much imitated. Other works include *Le Lépreux de la cité d'Aoste* (1811), a moving book which reflects his brother's political ideas; *La Jeune Sibérienne* (1823); and *Les Prisonniers du Caucase* (1825). He was also interested in science and published a *Mémoire sur l'oxydation de l'or* (1811). He died in St. Petersburg on June 13, 1852. (R. D.)

MAITLAND, EDWARD (1824–1897), English eccentric mystic and humanitarian, was born the son of a Brighton clergyman, at Ipswich, Oct. 27, 1824, graduated from Caius college, Cambridge, in 1847 and began his career by participating in the Californian and Australian gold rushes. Returning to England in 1857 he became best known for his association with the even more eccentric Anna Kingsford, variously vegetarian, antivivisectionist and theosophist, with whom he published *The Keys of the Creeds* (1875) and *The Perfect Way: or the Finding of Christ* (1882), and founded the Hermetic society in 1884 "to promote the comparative study of the philosophical and religious systems of the East and of the West." After her death he founded the Esoteric Christian union and wrote her *Life and Letters*, incorporating much autobiographical material (1896). He died at Tonbridge on Oct. 2, 1897. (G. F. A. B.)

MAITLAND, FREDERIC WILLIAM (1850–1906), English jurist and historian of law, whose special contribution was in bringing the historical and comparative methods to bear upon the development of English law and institutions, was born on May 28, 1850, in London. Educated at Eton and at Trinity college, Cambridge, he was called to the bar in 1876. Trained as a conveyancer, he later turned to legal history and comparative jurisprudence and was appointed reader in English law (1884) and then Downing professor (1888) at Cambridge. As a historian he has been ranked with Gibbon and Macaulay. Despite delicate health, his publications were numerous. Among the most important are *Justice and Police* (1885), *Bracton's Note-Book* (1887), *Memo-randa de Parlamento* (1893), *History of English Law*, with Sir F. Pollock, 1895; 2nd ed. 1898), *Domesday Book and Beyond*

(1897), *Township and Borough* (1898), *Canon Law in England* (1898) and *English Law and the Renaissance* (1901). His papers were published in *Collected Papers* (1911) and *Selected Historical Essays* (1957). He edited several important volumes for the Selden society, founded by him and others for the study of English law. His works are characterized by vigour, clarity and grace of style; they reflect immensity of intellectual grasp, vast knowledge, mastery of original sources, and the most exacting standards of scholarship. He died at Las Palmas, Canary Islands, on Dec. 19, 1906.

MAITLAND, JOHN (MAITLAND OF THIRLESTANE) (1543–1595), chancellor of Scotland (1587–95) and prominent adviser to James VI, was the second son of Sir Richard Maitland of Lethington and the younger brother of William Maitland of Lethington. He was born in 1543 and after completing his education in France succeeded his father as keeper of the privy seal in April 1567 and became a lord of session in June 1568. He was forfeited in May 1571 for supporting Mary Stuart and was imprisoned for a time in Tantallon castle by the regent Morton. After Morton's fall Maitland was restored to the bench in 1581, became a member of the privy council in 1583 and was knighted and appointed secretary in 1584. On the fall of the powerful favourites, James Stewart, earl of Arran, and Patrick, master of Gray, at which he connived, Maitland became the principal adviser of James VI in 1586, pursuing a policy of an alliance with England, compromise with the kirk and the creation of an official class independent of the aristocracy. He was appointed chancellor on July 29, 1587, and was created Baron Thirlestane on May 17, 1590. His great influence aroused the jealousy of the nobles, of the queen and particularly of Francis Stewart, earl of Bothwell. After the murder of the earl of Moray by the earl of Huntly in Feb. 1592, which was popularly attributed to the chancellor, his enemies combined to bring about his fall. Maitland had to leave the court for a time, and although he sponsored the so-called golden act (1592) recognizing the presbyterian structure of the kirk and was subsequently reconciled with the queen and others, he never recovered his earlier power. Nevertheless, he retained the chancellorship until his death on Oct. 3, 1595.

See M. Lee, *John Maitland of Thirlestane and the Foundation of the Stewart Despotism in Scotland* (1959). (J. Lx.)

MAITLAND, SIR RICHARD (LORD LETHINGTON) (1496–1586), Scottish poet, lawyer, statesman and compiler of an important collection of Scottish verse. "Manly Maitland," as he was called in an epitaph, was the son of Sir William Maitland of Lethington, who was killed at Flodden. He studied law at St. Andrews and Paris, served James V and was keeper of the Great Seal (1562–67) under Queen Mary. Although he went blind about 1561, he remained active as a judge until 1584 and busied himself with writing and collecting Scottish poetry. He died on March 20, 1586. Maitland's poems reflect the troubled condition of Scotland in his time. Many have social and political themes, which they treat sometimes satirically, sometimes with the meditative seriousness of an old and blind man who loves his country and who asks his more fanatical and intolerant contemporaries, "How suld our commonweill endure?" They have frequently a nice and laconic strength and a metrical expressiveness, both reminiscent of his English contemporary, Sir Thomas Wyatt. Maitland included his own poems in his valuable collection of Scottish poetry known as the *Maitland Folio Manuscript* (begun about 1570), and his daughter added others while she compiled the smaller anthology called the *Maitland Quarto Manuscript* (1586). The 183 leaves of the folio and the 138 leaves of the quarto also contain a selection of works by Robert Henryson, William Dunbar, Gavin Douglas and other poets of the period. Maitland's services to Scottish history and literature were commemorated by the foundation of the Maitland club in 1828 to continue their study.

Smith, *Specimens of Middle Scots* (1902); the Maitland Club's editions of Maitland's *Poems* (1830) and his *Historie and Chronicle of the Hous of Seytoun* (1829). See also G. Eyre-Todd, *Scottish Poetry of the 16th Century* (1892).

(E. G. M.)

MAITLAND, WILLIAM (MAITLAND OF LETHINGTON) (c. 1528–1573), Scottish statesman and staunch supporter of Mary Stuart, was the eldest son of Sir Richard Maitland and was born, probably at Lethington, c. 1528. Educated at St. Andrews university and on the continent, he became secretary to the regent, Mary of Lorraine, in 1558. Joining the lords of the congregation in 1559, he helped to expel the French from Scotland by the treaties of Berwick (Feb. 1560) and Edinburgh (July 1560). He became secretary to Mary Stuart and a lord of session in 1561, and thereafter his overriding aim was to secure her recognition as successor to the English crown. He believed that this would pacify religious issues in Scotland by abating the political influence of Mary's Roman Catholicism. He also tried to restrain the Protestant extremists by holding a public debate with John Knox in 1564 on resistance to an idolatrous prince. Maitland favoured Mary's marriage to Henry Stewart, Lord Darnley, in July 1565, but after the murder of David Rizzio, the queen's favourite, the ascendancy of James Hepburn, earl of Bothwell, forced him to flee the court in fear of his life. He was reconciled to Bothwell in Sept. 1566, but after Darnley's murder (in which Maitland was implicated) in Feb. 1567, he opposed Mary's marriage to Bothwell and joined the opposition.

On Bothwell's flight, Maitland worked persistently for reconciliation and the restoration of Mary. At the York and Westminster conferences in 1568–69, he tried to exculpate the queen from the Darnley murder and to promote her marriage to the duke of Norfolk. Maitland broke with the regent Moray's party over this and was arrested in Sept. 1569 for complicity in Darnley's death, but he was later rescued and led the queen's supporters in the civil war following Moray's murder (1570). Maitland held Edinburgh castle until forced to capitulate in May 1573 and subsequently died in prison at Leith on or about June 9, 1573.

Accused by contemporaries of faithlessness, he tried to promote the best interests of Mary Stuart, often in defiance of her own actions, but he allowed his own policy to become obsessive and underestimated the force of contemporary religious feeling.

See E. Russell, *Maitland of Lethington* (1912). (J. Lx.)

MAITLAND, a city of New South Wales, Austr., situated in the lower valley of the Hunter river, 20 mi. N.W. of Newcastle. Pop. (1961) 27,353. Maitland is subject to flooding, but its suburbs, East Maitland, Morpeth, Tenambit, Lorn, Telarah and Ruthersford, are on high ground to the east and west. In the adjacent farming area, mixed farming is extensively practised, as well as dairying and beekeeping. Lucerne, corn (maize), millet, potatoes and vegetables are grown. Maitland is the market centre for stock and processes meat for local, metropolitan and export markets. Industries include the manufacture of rayon and textiles, clothing, bricks, tiles and pipes, and light engineering. There are bus services to all centres within 30 mi. and the city is served by the Newcastle suburban railway, while express train services link the district with Sydney and the northern half of New South Wales.

Cessnock (pop. [1961] 35,281) lies 18 mi. S.W. of Maitland and is the market town of the south Maitland coal fields, which cover an area of about 100 sq.mi. and contain more than 1,500,000,000 tons of reserves. Average annual production is about 9,000,000 tons of excellent quality coal. Cessnock is also the centre of a good agricultural district.

MAITRAKA, the name of an Indian dynasty that ruled in Gujarat and Saurashtra (Kathiawar) from the end of the 5th to the 8th century A.D. The capital of the Maitrakas was Valabhi, the modern Wala (Vala), near the eastern coast of the Saurashtra peninsula. The founder of the line, Bhatarka, was a general who apparently profited by the decay of the Gupta empire and established himself as the ruler of the region. Although the early Maitraka kings were loosely feudatory to the Guptas, they were in fact independent. Under the powerful Siladitya I (end of 6th century) the kingdom became very influential, and its rule extended

into Malwa and Rajasthan. Later, however, the Maitrakas suffered at the hands of the Chalukyas of the Deccan and of Harsha (q.v.) of Kannauj.

The Maitrakas revived after the death of Harsha and became fully independent, but in the 8th century new enemies appeared. These were the Arabs, who established themselves in Sind in 712. Thenceforward the Maitrakas were continually attacked by them, and the last Maitraka king, Siladitya VI, apparently perished when Valabhi was razed to the ground (c. A.D. 780). The invaders did not hold the territory, however, and the region came under the influence of the rising Rashtrakuta dynasty of the Deccan.

The Maitraka kings were great patrons of religious foundations. Their kingdom was an important centre of Buddhism and, according to tradition, it was in Valabhi that the Svetambara Jain canon was codified.

See Niharranjan Ray, "The Maitrakas of Valabhi," *Indian Historical Quarterly*, vol. iv, pp. 453-474 (1928); Krishnakumari J. Virji, *Ancient History of Saurashtra* (1955). (A. L. BA.)

MAITREYA (literally, "benevolent"), the name of the Bodhisattva who is to be the next future Buddha. Buddhism holds that its truths have been and will be taught by numerous Buddhas, who arise in succession. Maitreya (Pali, Metteyya) is believed to be the next after Sakyamuni (see GAUTAMA BUDDHA), or the fifth among 1,000 Buddhas. The theory of recurrent Buddhas may not be primitive but it certainly arose before the close of the Pali canon, as Metteyya is mentioned there (*Digha Nikaya*, no. 26; *Buddhavamsa*, ch. 27, etc.). According to the later belief he is the lord of the Tushita heaven, due to be born in this world after the lapse of 5,670,000,000 years and to save living beings.

Maitreya or Maitreyanatha is also the name of a Buddhist master (c. A.D. 270-350), the founder of the Yogacara school, who was later identified with Maitreya Bodhisattva. He was the teacher of Asanga, a great Buddhist philosopher, and composed some philosophical works.

Abegg, *Der Messiasglaube in Indien und Iran* (1928); Hakuji Ui, "Maitreya as an Historical Personage," in *Indian Studies in Honor of Charles Rockwell Lanman* (1929); G. Tucci, *On Some Aspects of the Doctrines of Maitreya (māiha) and Asaṅga* (1930), and *Minor Buddhist Texts* (1956). (H. NA.)

MAIZE (CORN or INDIAN CORN), the principal food plant of America. The word maize, derived from the Arawak Indian word *mā-hiz*, was formerly preferred in international usage since corn, the term by which the plant is known in the United States and Canada, was in many countries synonymous with grain and was applied to any cereal. The botanical name is *Zea mays*. The Spanish equivalent, *maíz*, is still used in the Spanish-speaking countries of America, but elsewhere in the world wherever English is commonly spoken the word maize is giving way to corn. In southwestern United States maize means specifically a variety of sorghum, milo maize. See CORN; see also references under "Maize" in the Index.

MAJANO (MALANO), **BENEDETTO DA** (1442-1497), Italian sculptor, was born at Majano, near Florence. His earliest surviving work is the shrine of S. Savino (1468-70) in Faenza cathedral. Between 1470 and 1475 he was engaged on the altar of Sta. Fina in the Collegiata at S. Gimignano, in a chapel designed by his elder brother Giuliano (1468) and decorated with frescoes by Ghirlandajo. The connection between Benedetto da Majano and Ghirlandajo is reflected in the five narrative reliefs in Benedetto's masterpiece, the pulpit in Sta. Croce in Florence (probably 1472). A bust of Pietro Mellini (Museo Nazionale, Florence), by whom the pulpit was commissioned, is dated 1474 and reveals the same accumulation of naturalistic detail as is found in the male portraits of Ghirlandajo. The ornate decorative parts of the Sta. Croce pulpit are of great distinction and have a counterpart in the marble doorway of the Sala dei Gigli in the Palazzo Vecchio, Florence.

After this time Benedetto was employed on two major works for the church of Monte Oliveto in Naples, the tomb of Mary of Aragon (d. 1470), begun by Rossellino, and an altarpiece of the Annunciation (1489). Concurrently, he was employed by Filippo

Strozzi, of whom he made a portrait bust (marble in the Louvre, Paris; terra cotta in the Kaiser Friedrich museum, Berlin) and whose tomb in Sta. Maria Novella, Florence, he completed after 1491. His last major works, the altar of S. Bartolo in S. Agostino at S. Gimignano (1493-95) and an unfinished group representing the "Coronation of Ferdinand of Aragon" (Museo Nazionale) show some decline in quality.

As a sculptor Majano occupies a place above Mino da Fiesole and below Andrea del Verrocchio, and his work depends for its effect less on invention and originality than on unflinching taste and an exceptionally high level of technical skill. He was also an architect. Majano died on May 24, 1497.

See L. Dussler, *Benedetto da Majano* (1924).

(J. W. P.-H.)

MAJESTY awe-inspiring greatness, in particular the attribute of divine or sovereign power. The ancient Romans spoke of the majesty (*maiestas*) of the republic or of the Roman people, violation of which entailed a charge "of injured majesty," *crimen laesae maiestatis*; i.e., of lèse-majesté or treason (q.v.). Under the principate the majesty of the state was transferred to the emperor's person, whose *maiestas augustalis* was protected from disrespect by extension of the law of treason. An early example of the modern usage of the term as an honorific form of address occurs in a letter of Q. Aurelius Symmachus to Theodosius I, whom he calls "Your Majesty," after which it becomes frequent in addresses to the western emperors (cf. the *megaleiotes* of the Byzantines).

In the middle ages the Holy Roman emperors had "majesty" from the time of Louis the Pious but kings (e.g., Henry II of England), popes, cardinals and archbishops also enjoyed it occasionally; Hugh, count of Champagne, even referred to his own in a letter to the monks of St. Remy (1114) and the citizens of Ghent ascribed it to Philip the Good, duke of Burgundy (1453). In these instances, however, one of the parties to the communication recognized the other as his superior: no precedent was therefore established for solving the problems that obstructed diplomacy when the emperor proved unwilling to accord "majesty" to other sovereigns who claimed it. Having withheld it from Francis I of France at the signing of the treaty of Cambrai (1529), Charles V eventually allowed it to him at the peace of Crépny-en-Laonnois (1544), with the distinction however that Charles's "majesty" was there specified as "Caesarean" while Francis' was only "Royal." The kings of Spain, on the other hand, managed to retain the "majesty" acquired when Charles was both king of Spain and emperor.

Embarrassments recurred (notably in the preliminaries of the peace of Westphalia) until the solution adumbrated in 1544 was generally adopted in the 18th century, when the "majesty" of the several kings was determined by qualification with the special epithets that the papacy had given them as kings: the king of France then, as "Most Christian king," became "His Most Christian Majesty"; the king of Spain, "His Catholic"; and the king of Portugal, "His Most Faithful." Maria Theresa, during the War of the Austrian Succession, had "Apostolic Majesty" as undisputed successor of the "Apostolic kings" of Hungary; later, their right to the empire established, she and her successors had "Imperial and Apostolic."

The sovereign of the United Kingdom is "His" or "Her Britannic Majesty" for international purposes. "His Majesty" is usually enough for any ruler within his own realm but may be amplified: "His Sacred" (16th-17th century), "His Most Gracious" and "His Most Excellent Majesty" are English forms.

MAJOLICA, a name properly applied to a species of Italian ware in which the body is coated with a tin enamel, on which a painted decoration is laid and fired. It is also applied to similar wares made in imitation of the Italian ware in other countries. The word in Italian is *maiolica*. See POTTERY AND PORCELAIN.

MAJOR, a military rank standing above captain. Originally the term was used adjectivally in the title sergeant major, the "third principal officer in a regiment" (Ward, 1639), now the major. In the 16th and 17th centuries there was a similarity between the duties of the sergeant, sergeant major and sergeant major general, in that they attended to the drill and administration of a com-

pany, a regiment and an army, respectively. In conversation, sergeant major was abbreviated to major and sergeant major general to major general, whence the modern titles of major and major general derive. In the case of sergeant major the sergeant was dropped about 1660.

In the 17th century the duties of a major were a combination of those now performed by the major (second in command) and sergeant major, but on the introduction of adjutants he was relieved of much of the routine work. The brigade major corresponds in a higher sphere to the adjutant of a battalion. Such expressions as town major and fort major indicate the purpose of the appointment.

The rank of major has always been below that of lieutenant colonel. In a regiment commanded by a colonel, he was the third in command; in a battalion commanded by a lieutenant colonel, he was second in command. In the larger organizations of the 20th century a regiment might have three or more majors, each commanding a battalion.

Drum major was an ancient title in the British service and was adopted by the U.S. army early in its history. The drum major was responsible for training the regimental drummers and often had the additional functions of regimental postman and banker. The title sergeant major was introduced as a noncommissioned rank in the British service early in the 18th century and was elevated to warrant rank in 1881. In the U.S. army it has usually indicated the principal administrative noncommissioned officer of a unit, the chief assistant to its adjutant.

See also **INSIGNIA, MILITARY; OFFICERS, MILITARY**. For the musical meaning of the term major see **HARMONY**. (F. P. T.)

MAJORCA (Sp. **MALLORCA**), a Spanish island, the largest of the Balearic Islands, located in the western Mediterranean sea. Area 1,405 sq.mi. Pop. (1960) 363,156. Palma (*q.v.*) is the capital of Majorca and of Balears province.

Two mountainous regions, trending southwest-northeast and each about 50 mi. in length, occupy the western and eastern thirds of the island, being separated by a depression which terminates in Palma bay on the south and Alcudia and Pollensa bays on the north. The northwestern mountains are the higher range, Puig Mayor attaining 4,734 ft. Precipitous cliffs, often over 1,000 ft. high compose much of the north coast. The varied landscape includes pine forests, olive groves, torrent gullies, intensively terraced slopes and fertile valleys such as those of Valldemosa and Sóller. The much less rugged southeastern hills are especially famous for their extensive limestone caves and subterranean lakes. The central lowland, benefiting from the shelter provided by the northwestern mountains, is a rich agricultural zone with the typical two-tier cultivation of olives, figs, apricots, oranges, almonds and vines with crops of cereals, lucerne and legumes among the trees, and stock raising.

The island's economy is based principally on these agricultural products and on the tourist industry, although marble and building-stone quarries, superphosphate works and light industries manufacturing pottery, glassware, shoes, rugs and souvenirs provide some employment. The wines produced are light but of good quality, those of Felanitx and Binisalem being especially notable.

The road system fans out from Palma to all parts of the island. Four railway lines link Palma with Inca (pop. 13,816 [mun.]) and La Puebla (9,931 [mun.]), Manacor (19,224 [mun.]) and Artá (5,401), Felanitx (11,797 [mun.]) and Lluchmayor (10,664 [mun.]), and Santafí (5,082 [mun.]). The other principal municipalities are Pollensa (8,975 [mun.]) and Sóller (9,473 [mun.]) in the northern mountains. Maritime services connect the island with the mainland and the other Balearic islands. There are regular air services to Barcelona and Paris.

The fairs and colourful ceremonies, such as those of Pollensa during Holy Week, the mountain scenery, benign climate and the island's rich historical heritage attract thousands of visitors each year. At Valldemosa is the abandoned monastery where Chopin and George Sand stayed in Majorca and where Chopin wrote some of his finest mazurkas and preludes.

For history and archaeology see **BALEARIC ISLANDS**.

(G. J. B.)

MAJORIAN (**JULIUS MAJORIANUS**), Western Roman emperor from A.D. 457 to 461, was born of a distinguished military family and had himself served under Aëtius (*q.v.*). An old friend of Ricimer (*q.v.*), Majorian helped to overthrow the emperor Avitus (*q.v.*) in 456. Appointed master of the soldiers in 457, he inflicted a defeat on Alamannic invaders at Bellinzona, and on April 1, supported by Ricimer, was proclaimed emperor at Ravenna. In the summer he repulsed a landing in Campania of the Vandals of Gaiseric (*q.v.*). He was interested in the administration of his realm and tried to remove abuses in the collection of taxes and to protect the provincials from other forms of oppression. Most of his legislation dates from the year 458. In that same year he began to build a fleet with a view to recovering Africa from the Vandals. But he had not yet secured recognition in Gaul, where there was a movement to appoint Marcellinus as emperor. Majorian accordingly went to Gaul in 460, was praised in an extant panegyric by Sidonius Apollinaris, formed an alliance with the Visigothic king Theodoric II, and on March 28 was in Arles, assured of the support of the Gallo-Romans. His preparations for a war against the Vandals were now complete and in May 460 he crossed the Pyrenees into Spain. He marched to Cartagena, where the 300 ships of his fleet were assembled. But Gaiseric's fleet made a sudden descent on the Spanish coast and, aided by treachery, captured the larger part of the imperial navy in the bay of Alicante. Majorian was obliged to make a humiliating peace with the enemy and returned to Gaul. He then crossed the Alps, but having disbanded his army he fell into Ricimer's hands on Aug. 2, 461 and was compelled to abdicate. Five days later he was put to death at Tortona and several months afterward was succeeded as emperor by Libius Severus. His legislation and character make Majorian the only Western emperor of the 5th century to have some claim to greatness.

See J. B. Bury, *History of the Later Roman Empire*, vol. i, ch. 10 (1923); E. Stein, *Histoire du Bas-empire*, vol. i (1959). (E. A. T.)

MAJUNGA, the second largest town of the Malagasy Republic (Madagascar), lies on the northwest coast at the mouth of the Betsiboka river, whose estuary widens there into Bombetoka bay. Pop. (1963 est.) 41,648, of whom about 14,000 were foreigners; but immigrants from the Comoro Islands are almost as numerous as the Malagasy. Situated on the northeast corner of the bay, the town fronts both the estuary and the sea. It surrounds a low eminence and includes some fine streets, notably a water-front boulevard lined with coconut palms. Old buildings are confined to the harbour quarter which has some 19th-century Arabian houses; modern buildings include the Roman Catholic cathedral.

As a port, Majunga is of significance chiefly for transshipment, and about 300,000 tons of shipping are handled annually. It is linked by road with Diégo-Suarez and with Antananarivo (Tananarive), the capital (about 225 mi. S.S.E.). Air services to other centres in the republic use Fleuret Davioud airport, 4 mi. from Majunga. Industries include the processing of agricultural products (raffia, sisal, rice, edible oils), meat canning and the manufacture of soap, sugar and cement.

Majunga served as the base for the French expeditionary force that in 1895 advanced on Antananarivo and established a protectorate over the country.

MAJUNGA PROVINCE (pop. [1963 est.] 730,533; area 57,924 sq.mi.) rises eastward to the Tsaratanana massif in the central highlands. Coffee, rice, sugar, cassava and fibres are cultivated, hardwood timbers are exploited and beef cattle are raised. The offshore island of Nosy Be (*q.v.*) in the Mozambique channel is part of the province. (J. Ar.)

MAKARIOS III (**MIKHAIL KHRISTODOULOU MOUSKOS**) (1913–), archbishop and primate of the Orthodox Church of Cyprus and national leader of the island's Greek population, was born at Ano Panaya, near Paphos, on Aug. 13, 1913. Educated at the Pan-Cyprian gymnasium in Nicosia and at the University of Athens, he was ordained priest in 1946 with the name of Makarios. He went to the United States to continue his studies at Boston university, but returned to Cyprus in 1948, when he was elected bishop of Citium. He at once began to engage in politics and organized a national movement for *enosis* (union) with Greece.

In 1950 he was unanimously elected archbishop and ethnarch (national leader) of Cyprus. In 1955 he proposed that the British government should recognize the Cypriot people's right to self-determination. In March 1956 he was deported to the Seychelles Islands. Released from exile on March 28, 1957, he did not return to Cyprus until March 1959, after the signing of the London agreement on the future of Cyprus. On Dec. 14, 1959, he was elected president of the Republic of Cyprus, taking office on Aug. 16, 1960, when Cyprus attained full independence. In Oct. 1963, convinced that the 1959 constitution was unworkable, he suggested its revision to the Turkish Cypriot minority. The rejection of his proposal by the Ankara Turks (Dec. 1963) precipitated a new and serious crisis. See also *CYPRUS: History*.

MAKART, HANS (1840–1884), Austrian painter, who became the most celebrated painter of the great bourgeois epoch in Vienna, was born in Salzburg on May 29, 1840. He got his decisive training in Munich under Karl von Piloty, the leading historical painter at that time. He gave himself over entirely to a superficial, idealized historicalism, even in his portraiture, taking the 16th-century Venetians and Van Dyck and Rubens as his models in composition and colour. Makart lived in Vienna from 1869 and died there, Oct. 3, 1884. In 1879, when he was at the peak of his fame, he undertook to design the festal procession which was to celebrate the silver wedding of the emperor Francis Joseph I and the empress Elizabeth.

Makart's art, with its riotous, decorative grandiloquence, was in general the kind which is destined to fade quickly. But it is not difficult to recognize in many details and in individual works no small talent as a painter and an unusual gift for colour.

Important works are in the galleries of Vienna, Berlin, Hamburg and Stuttgart. He also executed a series of decorative lunettes for the Kunsthistorisches museum in Vienna. His historical pictures include "Caterina Cornaro" (1873), "The Entry of Charles V Into Antwerp" (1878) and "The Plague in Florence" (1867–68); other works are "The Burg Theatre Actress Charlotte Wolter as Messalina" (1876) and "The Triumph of Ariadne" (1873).

See Emil Pirchan, *Hans Makart* (1954). (F. NY.)

MAKASAR (MACASSAR), the chief port and largest city in the island of Celebes (Sulawesi), Indonesia, and capital of the province of Sulawesi Selatan/Tenggara (South-Southeast Sulawesi). Pop. (1961) 384,159 (municipality), including a large number of foreign nationals, particularly Chinese. The city is picturesque when seen from the sea. Parallel roads run from the harbour through the old city with its rows of 17th-century houses built close together and its open squares to the old Fort Rotterdam, originally built by the Portuguese. Facing the fort is a large green square, surrounded by official buildings and business premises. Gaily coloured, plaited basketry is an outstanding feature of Makasarese markets. The city lies on the western side of the most southerly peninsula of Celebes. Its situation is low and the immediately surrounding country swampy. The forest-clad hills of Maros, however, and the beautiful waterfall of Bantimurung are nearby attractions. Near the city is the grave of Dipa Negara (Diponegoro), leader of the Java rebellion in 1825 against the Dutch, who was exiled and died at Makasar.

The people, the Mangkasaras or Makasars, are a branch of the Malay people, similar to but not completely identical with the Bugis (q.v.), who inhabit the same region. (See *CELEBES: People*.)

The development of the port of Makasar was retarded by lack of harbour and wharf facilities until 1925, when new wharves, breakwaters and storage facilities were built. These were later modernized and extended. The main commodities exported from Makasar are copra, gums and resins, rubber, coffee and rattan; minor exports include kapok, ebony, maize, spices, hides and skins. The port is also a great centre for the distribution and transshipment of imports destined for other parts of Celebes, the Moluccas and the Lesser Sunda Islands. Makasar is connected by sea with the other ports of Indonesia and neighbouring countries, and by air with the major towns of Indonesia. A steam tramway runs from Makasar to Takalar, and good roads link Makasar with the hinterland.

Already a flourishing port when the Portuguese came to Indonesia in the 16th century, Makasar came under the control of the Dutch, who built a trading station there in 1607 (under the name of Vlaardingen) and who finally shattered the power of the sultan of Makasar in 1667. From that time it was in Dutch hands and was a useful base for their operations against the sultans of Celebes. The city was occupied by the Japanese from Feb. 1942 until 1945. In 1946 it was made the capital of the Dutch-sponsored state of East Indonesia (Indonesia Timur), and in 1949 it became part of the Indonesian republic.

MAKEMIE, FRANCIS (c. 1658–1707/08), American colonial Presbyterian clergyman and leader in forming the first American presbytery, was born in County Donegal, Ire., about 1658 and was educated at the University of Glasgow. In 1682 he was ordained by the Presbytery of Laggan, Ire., to go to America in response to a plea from a Colonel Steveris in Maryland. Makemie preached in Somerset county, Md., and in the Barbados for a number of years, supplementing his meagre income by trading. About 1690 he married the daughter of a wealthy merchant of Accomack, Va., and took up residence there. A year later he was in London, where he was associated with Increase Mather of Boston, with whom he had corresponded for several years, and with other Presbyterian and Congregationalist leaders.

For ten years he preached and traded between Accomack and the Barbados, and sought also to unite the various struggling Protestant churches of these areas in a common cause. However, Anglican attempts to silence him by arrest, and a severe controversy with George Keith, first a Quaker and then an Anglican zealot, awakened Makemie to the peril of the Dissenting churches in the colonies. His ties with the Boston ministers were continued, and in 1706 Makemie seems to have been the leading spirit in uniting several scattered churches and pastors in Virginia, Maryland, Pennsylvania and New Jersey into a presbytery. The following year Lord Cornbury of New York imprisoned Makemie and a colleague, John Hampton, for preaching on Long Island without licences. After several months of imprisonment, and a long and costly trial, Makemie was acquitted. Cornbury was soon recalled to London. Thereafter the provisions of the Toleration act in England were claimed by all Dissenters in the American colonies. In his trial Makemie had been aided by the Boston Congregationalist ministers, leading Dissenting ministers in London and prominent New York citizens.

Makemie's death occurred in late 1707 or early 1708. Six of his several controversial and sermonic publications are extant.

MAKE-UP (STAGE, MOTION PICTURE AND TELEVISION). As long as dramatic exposition has existed it has presumably been accompanied by some form of masquerade for the purpose of transforming the actor into the part he portrays. The use of make-up for cosmetic purposes dates from earliest historical times (see *COSMETICS AND COSMETOLOGY: COSTUME DESIGN, THEATRICAL*).

A suggestion of the simplicity and crudeness of the earliest make-up may be found in the religious rites of primitive races in modern times. The Patagonians, whose only form of dramatic movement was the swaying of their bodies and a monotonous mumbling of incantations, made up for the occasion by smearing their faces with chalk. Among the Australian aborigines, who rank somewhat higher in the ethnological scale, ritual ceremonies are enhanced by bodily adornments of wreaths, flowers and feathers worn over greased bodies and faces daubed with white clay.

The Aleuts use painted wooden masks representing demons and sea animals for their mystic rites, while the natives of the South Sea islands dress their heads with helmetlike structures into which are built masks of wood, reeds, tortoise shell and human skulls, sometimes decorated with vegetable substances to represent hair. Some of these islanders, e.g., the members of the Aru societies, discarded the mask and painted their faces red and their bodies black. The Indians of North America decorated their

bodies and faces with variously hued war paints; and their medicine men dressed for rituals in the skin and head of elk, bear, wolf or panther. See also MASK.

STAGE

Early.—The Chinese and Siamese theatre not only handed down an old tradition of masks but also made use of grotesquely painted faces of blue, green, ochre, vermilion and ghastly white for demons and spirits. Ancient Egyptian kings and priests wore wigs during official ceremonies; excavations dating back to 5000 B.C. reveal that eye and face paints were widely used. Persian warriors wove strands of jute into their marcelled beards.

In the procession of Dionysus (out of which grew the Greek drama) the god was represented with long hair and a long beard, two small horns projecting from his forehead, while the reeling Bacchantes appeared with faces smeared with wine dregs or mulberry juice. Some of the followers in the train portrayed dead souls clad in shrouds with their faces covered in white lead.

Medieval.—For miracle plays of the 14th century and onward, actors made up with startling realism as animals, devils, saints and angels. Much ingenuity in facial disguise was used in a medieval play called *The Acts of the Apostles*, wherein the spectators saw the eyes of St. Matthew drawn out of his head and watched Simon Magus change his face several times. In an early English Passion play, Christ and the apostles wore gilt wigs; the evil spirits appeared with bodies painted a reptilelike green and with huge ox and ram horns ornamenting their heads.

Renaissance.—A favourite farce actor in Paris during the reign of Henry IV was known as Gros Guillaume. His face make-up consisted of a thick coating of flour, which at comic moments, he sent flying into the eyes of his fellow actors by puffing out his fat cheeks; on his chin he wore a piece of white lamb's skin to represent a beard. The popular *commedia dell'arte* (q.v.) of the Italian theatre of the 16th and 17th centuries was performed by actors masked always in the typical grotesquerie of Harlequin, Pantaloon, Scaramouch, Capitano, etc. The white face of the modern circus clown is a direct inheritance from the French Pierrot, who in the 19th century discarded the mask of the *commedia dell'arte* clown, Pedrolino, and powdered his face with flour.

The English stage of Elizabeth I did away with the mask as a means of facial make-up. Instead of wearing the set expressions of the disguised Harlequins and Pantaloons, actors appeared in their own faces or were painted, bearded and wigged as the character required. Cosmetics were applied simply and obviously as there was no artificial lighting to soften disguise deficiencies. The theatre of Molière encountered few make-up difficulties. The customary long ringlets of the court were worn whatever the period of the play, whether Roman or contemporary, and the only beard necessary was the partly shaved mustache of the prevailing mode.

The 19th Century.—The ignoring of archaeological verity in make-up was characteristic of the English stage until after the time of David Garrick, who, for nearly every character, wore the white court wig of George III and as Romeo appeared as a British gentleman of his day. The art of make-up was studied but little before the beginning of the 19th century. Costume was clumsy and wigs and beards for character parts were of crude material. The early method of acting Shylock was as a comedy part that roused audiences to laughter. Thomas Doggett, a celebrated Shylock, wore a ridiculous red wig and beard for the part. The first actor to redeem the character from buffoonery was Charles Macklin, who presented him as sinister and black-bearded. Since Macklin, actors have varied the aspect of Shylock according to their fancy. Sir Henry Irving, for example, portrayed him as an elderly aristocrat.

The stage lighting of the period, provided first by candles and later by oil lamps, was dim and ineffectual; consequently, crudity in make-up passed unnoticed. When illuminating gas and calcium (lime) lights were introduced the necessity arose for greater circumspection in appearance. Make-up material, however, was still somewhat elemental and natural-appearing heads and complexions

were a rarity. (See also STAGE LIGHTING.)

(O. SK.; M. F.)

Modern.—With the introduction of electric lights into the theatre came the need for new make-up materials and more skilful techniques of application. Crude, inartistic effects could not be hidden under the revealing light of electricity. A new era of realism was dawning. Stick grease paint, a revolutionary invention, soon made its first appearance, and by 1890 the demand for stage make-up had warranted its manufacture on a commercial scale.

The importance of modern stage make-up cannot be overemphasized. If it were not used, the performer would discover quickly that the stage lighting system had removed all the colour from his complexion. Therefore, make-up is necessary to restore this colour and define the features of the face to ensure a natural appearance. It also helps the player to look and feel the part, and for most character interpretations it is absolutely essential. Standardized charts show the correct shades of make-up for various types of men, women and children.

MOTION PICTURES

During the early days of motion pictures, specially created make-up for the new medium was not available. The few players who wore make-up borrowed both materials and techniques from the stage. Characters invariably were standard types: hero, heroine and villain. The hero and heroine were heavily made up with painted lips, chalk-white faces and dark eyes. The villain depended only upon long "moustachios" and heavily painted black eyebrows. Stick grease paint of the theatre, however, was not satisfactory. Necessarily heavy applications made it impossible for the actor to appear natural looking in close-ups and the limited range of colours failed to meet requirements of motion-picture lighting and photography.

The first make-up designed expressly for motion pictures was created by Max Factor and was introduced by him in 1910. It was a light, semiliquid grease paint that was made available in jars in a precisely graduated range of tan-tone shades suitable for the lighting and orthochromatic film emulsion of that period. A short time later, this new grease paint became the first make-up to be made available in tubes.

Prior to 1928, there were no established standards for motion-picture lighting or the selection of make-up colours. But with the advent of panchromatic film and incandescent lights on the sets, a complete gradation of make-up shades was created that allowed every player, from those with the lightest to those with the darkest complexions, to appear true to type on the screen. In Feb. 1928, the Society of Motion Picture Engineers conducted a special series of tests to standardize the film, lighting and colours of make-up that were most effective for motion pictures. Obviously, the principal consideration was the appearance of the players and it was quickly determined that the make-up colours that had been used with orthochromatic film and arc lighting would have to be

(RIGHT, CULVER PICTURES, INC.)
LON CHANEY (LEFT) IN MAKE-UP FOR QUASIMODO IN "THE HUNCHBACK OF NOTRE DAME" AND (RIGHT) WITHOUT MAKE-UP

BY COURTESY OF TWENTIETH CENTURY FOX FILM CORPORATION
(LEFT) EARLY FILM MAKE-UP TECHNIQUES FOR THE ROLE OF CLEOPATRA AS PLAYED BY THEDA BARA, ABOUT 1915, AND (RIGHT) MODERN MAKE-UP APPLIED TO ELIZABETH TAYLOR FOR THE 1963 FILM "CLEOPATRA"

changed. As a result of these experiments, Max Factor created a completely new range of make-up colours called panchromatic make-up. For this achievement, he won a special Academy of Motion Picture Arts and Sciences award.

The main requisite in making-up a film player is the foundation colour, which is supplied in many distinctive tones ranging from a faint tan to a warm brown. Lipstick shades from light red to deep red are used, depending on the effect desired photographically. Eyeshadow and lining colours are selected in shades that are best suited to the individual. These may include blue and green as well as the panchromatic colours.

Motion-picture make-up is both corrective and creative. Make-up always must be applied skilfully, delicately and subtly so that facial expression will have natural freedom. The inexperienced person should remember that on the screen, particularly in close-ups, the face may be magnified many times larger than life-size. Consequently, every complexion flaw or crudely applied make-up artifice is clearly discernible. As a corrective art, make-up serves to (1) cover blemishes; (2) provide the face with a smooth and even colour tone for the most effective photography; (3) clearly define the facial features for more visibly expressive action; (4) make the player appear more attractive; and (5) ensure a uniform appearance before the camera. As a creative art, make-up enables the player to take on the appearance of almost any type of character. It can be his means of achieving a distinctive "screen personality." It can make the young appear to age believably and the old appear to look young again. Countless special make-up devices, effects and tricks are available. Tears can be produced by blowing fumes from a menthol tube into the eyes; the opening of the tube must be covered with gauze, however, to avoid blowing crystals into the eyes. Weird or comedy effects may be created by blocking out teeth with black tooth enamel. Realistic scars are made by applying nonflexible collodion with a brush.

Wigs, hairpieces and mustaches also are an integral part of the motion-picture make-up art and the ancient art of wigmaking has kept pace with the general advancement and perfection of make-up. Modern wigs and hairpieces are made of human hair. Each individual strand of hair is tied with a special needle into a lace-like foundation, which is stretched over a wooden wig block sculptured in the size and shape of the head contours. The most artistic beards and mustaches usually are made with crepe hair, which comes in various shades and is applied with spirit gum. Prepared beards and mustaches also are available. These are made on lace and can be used indefinitely. The bald or balding actor necessarily relies upon a hairpiece as a means of regaining a youthful appearance, but players of all ages and types depend upon hair goods to achieve realistic characterizations. The film *Marie Antoinette* (1938) called for 903 ornately fashioned white wigs and 1,200 less elaborate wigs for peasant extras. Another period

movie, *Forever Amber*, required 4,402 wigs. In Cecil B. De Mille's *The Ten Commandments* approximately 7,500 hairpieces, including beards and mustaches, were used. (See also WIG.)

Make-Up for Colour Films.—The introduction of colour to motion pictures brought make-up problems of the most serious nature. Existing grease paint made some players appear to have jaundice. Other faces became bright red, blue or green on the screen. As colour film processes were improved, the need for a new type of make-up became mandatory. The problem was not one of merely developing new colours. Entirely new materials had to be created. After initial tests were conducted with a liquid make-up, which did not prove satisfactory, experiments were started in a completely new field of make-up principles. This resulted in the introduction of a spectacularly successful solid (Pan-Cake) make-up that was applied with a moist sponge. Instead of covering and concealing skin surfaces, the new material provided a light, transparent film of colour. It was first used in *Walter Wanger's Vogues of 1938* and later in *The Goldwyn Follies*. For the first time in history players appeared realistic and lifelike enough to convey the impression that they might at any time step down from the screen into the theatre. Soon Pan-Cake Make-up started replacing grease paint to a large extent, even for black-and-white films. Another highly successful material introduced for colour motion-picture use was a creamy foundation in semi-solid stick form. Make-up charts show the correct colours to use for each type of colour film.

The basic techniques of applying make-up for colour photography are virtually the same as those for black-and-white photography, except that colour photography demands even greater skill and perfection in application methods.

TELEVISION

Special make-up for television was created in 1932 as the result of tests conducted in collaboration with the pioneer Don Lee experimental television station, W6XAO, in Los Angeles. Four major phases of technical development have occurred in the evolution of television make-up. The first creation was a light-coloured monotone. Next came the "painted Indian" effect that employed the multiple colours that televised most naturally during the intermediate period of television. This was followed by the development of the modern series of colours in solid and semisolid foundations for black-and-white television. The fourth step was the creation of special materials and shades for colour television.

Although 11 shades of make-up eventually became available for black-and-white television, the average foundation make-up needs for the medium could be fulfilled with 6 colours from the middle range (4 to 9) of numbers. Colours in the lower numbers are light pastel pinks and beiges. In the higher numbers, they are tan, brown and dark brown. Without make-up, performers cannot expect to have attractive complexions on television. Light complexions become ghostly white. Dark complexions look dirty. Men who may be closely shaved appear to need a shave. Everyday make-up shades used by women televise too light or too dark and ordinary lipstick colours usually wash out. Screen make-up shades are equally unsatisfactory.

For colour television, various new materials and countless variations of colours were tested. The success of colour television depends largely on presenting natural-appearing human skin tones. It might be relatively unimportant if a green dress appeared blue on a colour-receiving set, but a performer with a green face would be ludicrous. The problem is complicated by the requirement that faces must appear lifelike on colour television and at the same time appear natural in the simultaneous black-and-white telecast. The make-up for colour television is available in about 12 shades in both solid and semisolid forms.

MAKEYEVKA, a town of Donetsk (formerly Stalino) *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the headwaters of the small Grusekaya river, 11 km. (7 mi.) E. of Donetsk city. Pop. (1959) 857,575. The town was founded in 1899, with the establishment of a metallurgical works, and has grown into a major industrial centre. Modern industries include large integrated iron and steelworks and a steel tubes plant. Makeyevka has become one of the largest coal mining centres of the Donetsk basin or Donbass and second in population in the *oblast* only to Donetsk. There are also other metalworking and coke-chemical plants and factories for pneumatic machinery, shoemaking and food processing. In the 1920s it was known as Dmitrievsk.

(R. A. F.)

MAKHACHKALA, a port and administrative centre of the Dagestan Autonomous Soviet Socialist Republic, U.S.S.R., stands on the western shore of the Caspian sea, at the northern end of a narrow coastal plain. Pop. (1959) 119,334. It was founded as the Petrovskoye fortress in 1844, became Port Petrovski in 1857 and was renamed in 1921, after Mohammed Ali DaKhadaev Makhach, a Dagestani national hero. Deposits of petroleum occur nearby and a pipeline runs from the Grozny field 90 miles distant. There is a refinery and much oil is shipped. A fishing fleet is based there, and industries include textile and footwear manufacturing, brewing, fish canning and cement making. Makhachkala has a branch of the Soviet Academy of Sciences; medical, agricultural and pedagogic institutes, and it has a Kumyk national theatre.

(R. A. F.)

MAKÓ, a town in the steppelands of the southeastern extremity of Hungary, 217 km. (135 mi.) from Budapest by rail. Pop. (1960) 29,897 (mun.). It is the administrative centre of Csanád megye (county) and lies near the north bank of the Maros river, a few miles upstream from its junction with the Danube. Makó is in tradition and appearance a "village town," surrounded by a fertile countryside. The municipality was for long in possession of much farming land; this produced abundant grain and onion crops. The herds of large-horned cattle were also much prized. Makó has long-established milling industries and more recent textile factories. It is a market centre and a crossing point of secondary and minor roads. The journalist Joseph Pulitzer was born in Makó.

(H. G. S.)

MAKONDE, a Bantu-speaking people of southeastern Tanganyika, numbering about 285,000 in the 1960s. They are closely related to the neighbouring Mwera (120,000) and Makua (95,000). Both Makonde and Makua spread into Portuguese East Africa (the population figures are for Tanganyika only). All these peoples reckon matrilineal descent; they lack centralized chieftainship and are cultivators of grain crops. Many of them now emigrate to other parts of the east African coast, and there are several thousands in Zanzibar. They are renowned for their wood-carving. By 1967 they were contributing many guerrillas to the war being waged through the Mozambique Liberation Front against the Portuguese. See also TANZANIA, UNITED REPUBLIC OF; AFRICA: Ethnography (Anthropology): East Africa.

See J. Dias, *Portuguese Contribution to Cultural Anthropology* (1962).

(J. F. M. M.)

MAKRAN (MEKRAN; Persian MOKRAN), the coastal region of southeastern Iran and southwestern Pakistan, extending along the Gulf of Oman for about 600 mi. from Ra's (cape) al Kuh to Las Bela (southeast Baluchistan). The Makran of Pakistan is sometimes known as Kech-Makran; to distinguish it from the Iranian region. The two together constitute Makranat, a term used by several historians. The long lateral valley of the Kech (Kej) river and the name Makran are associated in early geographies, thus the area was called Kej-Macoran by Marco Polo, who visited it in 1294. The name is applied in particular to a former province of Iran, now included in Iranian-Baluchistan (q.v.), and to one of the former Baluchistan states, which became a district of the Kalat division on the integration of the state into the new province of West Pakistan in Oct. 1955.

The region consists mostly of mountains, the parallel ranges of which have a general structure east to west, including narrow valleys. Makran's 200-mi.-long sandy coast line in Pakistan is broken

by the magnificent cliffs of Malan; the headlands of Ormara and Gwadar, the precipitous coast of Jabal Zarain (near Pasni), the bays of Charbar (Chah Bahar) and Gwatar (Gavater) and the inlet near Ra's-e Meydani. The volcanic action that preceded the upheaval of recent strata and the folding of the edges of the interior highlands is evidenced by occasional volcanoes of boiling mud. The coast is indented with several harbours: Ormara East and West bays (Dimi Zarr and Padi Zarr), Khor Kalamat, Pasni, Gwadar and Charbar, all of which are rather difficult of approach because of the sand bar apparently extending all along the coast, probably the remains of a submerged ridge. They are all subject to lively surf under certain wind conditions. Gwadar, which, with about 300 sq. mi. of hinterland, belonged to the sultanate of Muscat and Oman till 1958, is the most important harbour. Except in the Kech (upper Dasht) valley and that of the Bolida, an affluent of the Kech, there is not much cultivation. These two picturesque valleys have thick date palm groves, croplands and orchards. The principal spring crops (*jopag*) are wheat and barley, and the autumn crop (*eraht*) is jowar. Dates are, however, the crop par excellence of Makran. *Laghati* (compressed dates) constitutes the staple food of the poor. Subterranean channels (*karez*), pools in river beds (*kaurjo*) and springs are, besides floods, the sources of irrigation. Hills are generally barren with sun-cracked crags and ridges, with parched valleys between. The Rakhshan and Mashkel rivers, sweeping down from the Kalat highlands in Pakistan and the Kuh-e Bam Posht uplands of Iran, unite to break through the hills northward and form the lake and swamps of the Hamun-i-Mashkel and define the northern limits of Makran. In their valleys are narrow strips of very advanced cultivation, especially of dates. The Makran coastal waters are famous for the quality of their fish.

The etymology of the name is uncertain. Some scholars regard Makran as a corruption of Mahi-Khoran ("fish eaters"), identified with the Ichthyophagi (now represented by the Meds) who were mentioned in the *Indica* of the Greek historian Arrian. According to Lord Curzon, who was governor general of India (1899-1905), the name is Dravidian, which appears as Makara in the *Brihat Sanhita* of Varaha-mihira in a list of tribes contiguous to India on the west. The country was the ancient Gedrosia of the Persian and Macedonian empires and was the scene of the famous retreat of Alexander from India in 325 B.C. Lying on the route from west to east, it has been significant in the history not only of Baluchistan but also of Iran and India. The suzerainty over Makran gravitated sometimes to the west and sometimes to the east. Local tradition relates that, of the indigenous races, the Rinds, Hot and Maliks, who held sway after the Arabs, were followed by Buledais, who in their turn were ousted by the Gichkis from India. These fell under the suzerainty of Kalat in the mid-18th century.

There is a prominent Arab element, for the Arabs held Makran before they conquered Sind. More than half are Balochi, who are middle-class cultivators. Darzadis, regarded as of aboriginal descent, form the second largest group. They have a fine physique and are mainly artisans. The fishermen are chiefly Meds and Koras. The coastal Negroes are descended from imported slaves.

MAKRAN DISTRICT of Pakistan had a population (1961) of 146,990. Turbat (4,578), formerly the capital of the state, is now the district headquarters. Panjgur (2,032) in the Rakhshan valley is the chief town in the interior, and Pasni the largest town on the coast. Its port is being developed on modern lines. (K. S. Ad.)

MALABAR CHRISTIANS, the name usually given to the autocephalous Eastern Church of the southwest coast of India acknowledging the Syrian Orthodox patriarch of Antioch as its spiritual head. The existence of an ancient church on the Malabar coast was made known to the west by the Portuguese, c. 1500. Its members, who believed that their founder was the apostle Thomas (q.v.), knew nothing of the papal obedience nor the Chalcedonian decrees. Regarded as Nestorian heretics and schismatics, they were made to accept the pope at the synod of Diamper (1599), but in 1653 about half became Syrian Orthodox in allegiance (see ANTIOCH, SYRIAN ORTHODOX PATRIARCHATE OF). In the 19th century, under the influence of English missionaries, a

reforming group broke away and came to be known as the Mar Thoma Church. A few families became Anglican. Thus, there are four sections: the Syrian Roman Catholic, the Syrian Orthodox, the Mar Thoma and those former Malabar Anglicans now in the Church of South India.

In the first half of the 20th century the Syrian Orthodox were deeply divided, one section recognizing the jurisdiction of the patriarch of Antioch, the other the Indian catholicos of the east. After much litigation, these two churches were again united in 1958. In worship and doctrine the Malabar Christians are purely Syrian; their liturgical language is Syriac, though largely translated into Malayalam. In culture and ways of life, however, they are Indian, and their family pride and communal exclusiveness enabled them to fit easily into the Hindu caste system. The 20th-century breakdown of caste and renewed contact with other churches has given them a wider outlook; they are to be found all over India.

See L. W. Brown, *The Indian Christians of St. Thomas* (1956).

(L. M. Sc.)

MALABAR COAST, a term long applied to the southern part of the western coast of India, roughly from Goa southward. Occasionally it has been extended to the whole western coast of peninsular India. Until 1956 Malabar was also the name of a district (whose chief town was Kozhikode or Calicut) in Madras. The Malabar coast is perhaps best defined as being coextensive with the old kingdom of Chera, thus including most of Kerala state together with parts of Kanara (now in Mysore) and lying between the Western Ghats or their southern extension and the sea. The people speak Malayalam and have many customs and traditions peculiarly their own. Cochin is the only important port.

The coast trends in a south-southeasterly direction with a few headlands and small bays. Powerful waves breaking on shore during the period of the southwest monsoon have piled up a continuous belt of sand dunes largely clothed with coconut palms that yield coconuts and coir. Behind this belt is an almost continuous succession of shallow lagoons and backwaters round which are rice-growing lands and numerous villages. Connected by artificial canals, they form sheltered waterways much used by local traffic. Inland the land rises in wet forested hills, with valuable timber, to the crest of the Ghats. The Southern railway from Madras, passing through the Palghat gap, reaches the coast south of Kozhikode and is continued northward to Mangalore.

(L. D. S.)

MALACCA, a state of Malaya in the Federation of Malaysia (*q.v.*), constituted in 1957 under a governor appointed on the advice of the federal government; a town of the same name is its administrative capital.

The state was previously a civil division known as Settlement of Malacca, a British colony which it became in 1824 by arrangement with the Dutch in exchange for Bencoolen (Bengkulu) and a few other minor places in west Sumatra following the Napoleonic Wars. (See *MALAYSIA*.) The state, covering 640 sq.mi., has a population of 361,152 (1963 est.); the racial composition according to official returns was 49.1% Malaysian, 41.5% Chinese and 8.1% Indian. It is shaped like a triangle and is framed by the west coast and boundaries with Johore to the south and Negri Sembilan to the north and east. Low hills reach the sea to form a coast that was more hospitable to settlement than were other parts of the west Malayan lowlands.

Substantial agricultural production of *padi* ("rice") was possible from early times. Malacca now has less forest than any other Malayan state; by the early 1960s it had about 27,000 ac. under *padi*, chiefly along the slow-flowing rivers, and 215,000 ac. under rubber. The rubber production indicates an evolution of highly commercialized agriculture consequent to early established overseas trade connections. Malaccan Chinese, now about a third of the rural population, were the first to go into rubber planting following its introduction by the British and there are now large areas of Chinese estates and small holdings. In the Kesang river to the south there is a little mining for tin (by Chinese) but production in the 1960s was insignificant. The Malays maintain their rice-growing tradition but, profiting by long contact with resident Chinese, many have also taken to small rubber holdings.

The state has mosques in the rural areas and Chinese temples in the villages; a strong Roman Catholic tradition is also maintained. There are small market towns at Alor Gajah and Jasin.

MALACCA town (pop. [1957] 69,848), roughly midway along the coast, lies astride the sluggish Malacca river 125 mi. N.W. of Singapore. Immediately to the south on a low hill stand the ruins of a 16th-century fort built by Afonso de Albuquerque, viceroy of the Portuguese Indies, who conquered Malacca to acquire the rich far eastern trade already established there by Chinese, Indians and Arabs. The small Malacca estuary, then kept open only by two long moles that deflected the heavy longshore drift, sheltered the Asian sailing craft from the strong local squalls, which were dangerous because of shallows, banks and rocks offshore. Early trading vessels were attracted there by local food supplies and freshwater springs at the foot of the Malacca hills. The approaches proved inadequate as European shipping increased in draft and volume.

Until World War II a railway spur linked Malacca to the main lines through the peninsula, but ocean-going commerce thereafter declined and the harbour facilities (limited to offshore anchorage) are negligible. Peninsular trunk-road traffic bypasses the state which however retains road links to Kuala Lumpur and Singapore, the Singapore road being hindered by ferries across the rivers of Johore.

The town is a sun-drenched, sleepy backwater with single-storied houses, including many relics of the Dutch and Portuguese colonial periods. It is now mostly occupied by Chinese, some of whose families have been settled there for four centuries and have adopted the dress and speech of the Malays, with whom they have intermarried; this mixed strain, together with Malay-Portuguese-Dutch admixtures, is a feature unique in Malayan peoples.

THE STRAIT OF MALACCA, a sea link between latitudes 6° N. and 1° N. from the Indian ocean to Singapore strait and the South China sea, has a funnel shape, barely 40 mi. wide in the south, broadening northward to 300 mi. between Sabang and the Kra isthmus. Subject to tides from the Indian ocean, the strait is silting on both sides, particularly south of Medan, where it has formed the huge, low-lying swamp forest of east Sumatra. It has been the scene of major historic movements of early Hindu colonists, of Arabic merchants trading oriental produce to classical and medieval Europe and of Portuguese, Dutch and British navigators and traders. During the 20th century the strait was the channel by which Chinese immigrants moved to trade and to settle along both Sumatran and Malayan shores, where all towns and villages contain large numbers of Chinese. The strait continues to be one of the world's most used shipping channels, almost a natural Suez canal, but intra-coastal trade is negligible. See also references under "Malacca" in the Index.

(E. H. G. D.)

MALACHI (MALACHIAS). BOOK OF, the last book of the English Protestant and the Eastern Orthodox Old Testament (followed in Roman Catholic Bibles by the Books of Maccabees) one of the 12 Minor Prophets; in the Hebrew Bible it appears at the end of the Prophets, the second of the three major divisions of the Hebrew canon (Law, Prophets and Writings). The book is anonymous, the name Malachi ("my messenger") being taken from the opening words of ch. iii, "Behold, I send my messenger to prepare the way before me." Since the two preceding sections of the canon of Scripture (Zech. ix-xi and xii-xiv) are also by general agreement anonymous compositions, and also, like Malachi, each begins with the curious word "oracle" (or, as in the King James and Douai versions, "burden"), it seems probable that these three collections of unidentified prophetic discourses were at one time simply added to the end of the book of the Minor Prophets as an appendix. Later, when it was felt desirable to have exactly 12 divisions, the first two of these anonymous collections were included in the Book of Zechariah while the third, of very different character and origin, was set apart as a separate division and given a title arbitrarily derived from iii, 1.

Contents and Themes.—The book may be outlined as follows:

- | | |
|-------------|------------------------------|
| i, 1: | superscription |
| i, 2-5: | punishment of the Edomites |
| i, 6-ii, 9: | corruption of the priesthood |

- ii, 10-16: degradation of marriage
 ii, 17-iii, 5: divine judgment to come
 iii, 6-12: sins of the common people
 iii, 13-iv, 3: argument based on the coming judgment
 iv, 4-6: conclusion

The time was one of spiritual depression. The promised age of supernatural prosperity and universal dominion which should have followed the end of the Babylonian Exile (Isa. xlviii, 20 ff.; xlix, 22 ff.; liv, 1 ff.) had failed to materialize; the small body of faithful people who had attempted to restore the glories of ancient Israel found that life in their ancestral land was a series of discouragements—poverty and famine (Hag. i, 6), drought (Hag. i, 11), internal strife and social disorder (Isa. lix, 3-15). As a result, the services of the Temple were neglected and there was widespread skepticism in regard to the justice of God and his good will toward his people. It was to this situation that the oracles preserved in the Book of Malachi were addressed. The prophet had a threefold answer to those who doubted the justice of God: First of all, he pointed out that God had but recently manifested his continuing favour toward the people of Israel ("Jacob") by punishing their treacherous neighbours, the Edomites ("Esau"), who had been driven out of their homeland by Arabs from the desert (the Nabataeans). In the second place, if Israel failed to be prosperous, it was not to be wondered at in view of the nation's shameful neglect of the Temple services, a neglect to which no parallel could be found even among the heathen (i, 11). Finally, even though there might seem to be grounds for complaint in the apparent inequities of the present age, these would be eliminated in the final divine judgment which was to come, when it would be evident who had served God faithfully and who had not (iii, 18).

Literary History.—Although neither the name of the prophet nor the events of his life are known, there is a general consensus as to his date and the historical circumstances in which his oracles were uttered. The land was ruled by a governor (i, 8), not a native king; the Temple had been rebuilt (i, 10; iii, 1, 10) and the services had been carried on long enough for both priests and people to become somewhat weary of them (i, 7, 12, 13); the lethargic spiritual life of the community had not yet been stirred by the reforms of Nehemiah and Ezra (whose activity is almost certainly to be dated after 444 B.C.); while the Law code presupposed by the book seems to be that of Deuteronomy (introduced in 621 B.C.), rather than the later Priestly Code, which modern scholars are inclined to associate with the work of Ezra. All these indications point to a date in the Persian period toward the middle of the 5th century B.C. Inasmuch as the abuses attacked by the prophet are similar to those that were to be the principal concern of Nehemiah, the book may safely be dated shortly before his arrival, and therefore c. 450 B.C.

The last three verses of ch. iv, important as background for certain passages in the New Testament, are not properly a part of Malachi but are rather a late editorial conclusion to the entire collection of the Twelve (Minor) Prophets.

Interpretation.—Brief as it is, Malachi contains several remarkable passages which are worthy of special notice: In i, 11 the prophet suggests that the worship that the gentiles ignorantly offer to God may be more pleasing than the careless, though better instructed, worship of his own people (the translation of the Revised Standard version is to be preferred). In ii, 10 (with which cf. i, 6), the doctrine of God's Fatherhood is made the major premise of an argument that men (the Jews, at least) should live as brothers. In the following verses this principle is applied specifically to the manner in which the privilege of divorce was currently abused, the passage concluding with the striking words "I hate divorce, says the Lord" (ii, 16). These magnanimous sentiments, which are scarcely paralleled elsewhere in the Old Testament, show that a priestly and ritualistic type of Judaism such as that represented in this book was not necessarily incompatible with profound ethical sensitivity.

BIBLIOGRAPHY.—The chief modern commentaries in German are those by F. Horst (1936, 1954) and K. Elliger (1956); in English, there are commentaries by G. A. Smith (1898, 1927), S. R. Driver in the *Century Bible* (1906), J. M. P. Smith in the *International Critical Commentary* (1912), and R. C. Denton in the *Interpreter's Bible* (1956).

(R. C. DE.)

MALACHITE, a bright green mineral, consisting of a basic copper carbonate. It is one of the commonest ores of copper and perhaps the most conspicuous, being a useful guide in prospecting. It is found in the upper oxidized portions of copper deposits, and is formed by the action of water, air and carbon dioxide on primary copper sulfides, especially where calcium carbonate is present. The soluble copper salts set free by oxidation of the sulfides react with limestone or other carbonates and precipitate the insoluble malachite. The mineral is found in nearly all copper-mining districts; specially fine specimens have come from various mines in the U.S.S.R., where it has often been used as a polished ornamental stone. Other well-known localities for good specimens have been the Copper Queen mine, Bisbee, Ariz., the old Burra Burra mines, Koorunga, South Australia, and southwest Africa.

The composition of malachite is $\text{CuCO}_3\text{Cu}(\text{OH})_2$. It belongs to the monoclinic system, but rarely forms good crystals, occurring mostly as nodular, botryoidal (grape-like) or reniform (kidney-shaped) masses, with pronounced radial and concentric structure, successive layers often varying much in colour. It may also be quite compact or earthy and often forms thin films or mere stains on rocks. It is very commonly associated with the deep blue azurite (*q.v.*). The density is about 4 and the hardness 3.5-4.0. It is soluble in acids with effervescence. (R. H. RA.)

MALACHOWSKI, STANISLAW (1735-1809), Polish statesman who dominated the historic Four Years' diet of 1788-92, was born at Konskie, the son of the grand chancellor of the crown, Jan Malachowski (1698-1762). When the diet met in 1788, he was elected its marshal or speaker. Tactful, authoritative and conspicuously honest, he worked tirelessly for reform of the Polish state in order to give it sound finances and a strong army; and he was one of the framers of the constitution of May 3, 1791, exceeding all his colleagues in liberalism and advocating the extension of the franchise to the towns (*see* POLAND: *History*).

In 1807, during the Napoleonic Wars, Malachowski was appointed head of the executive committee set up in Warsaw after its evacuation by the Prussians; and when the duchy of Warsaw was created he became president of the senate. In the negotiations with the Austrian government concerning the Galician salt mines he assisted the treasury by mortgaging all his estates as an additional guarantee. He died in Warsaw in 1809.

See E. Michalski, *Stanisław Malachowski, marszałek Sejmu Czteroletniego* (1936).

MALACHY, SAINT (MAEL MAEDOC UA MORGAT) (1094-1148), archbishop of Armagh and papal legate in Ireland, the prominent figure of church reform in the 12th century, was the son of the *ard fer leigin* (chief lecturer) at the school of Armagh, Mugron Ua Morgair. Before 1119, Malachy put himself under the spiritual direction of the recluse Imar Ua hAedagain. He was ordained priest in 1119. When Cellach, the reforming bishop of Armagh, took into his hands the bishopric of Dublin, vacant by the death of Samuel (1121), he appointed Malachy to rule Armagh. The young priest undertook to bring the Irish church to accept the general reformation then in full motion on the continent and associated with Pope Gregory VII. Malachy later returned to the monastic life, at Lismore, under the guidance of another reformer, Mael Isa Ua hAinmire (Malchus). In 1124 he was consecrated bishop of Connor (and Down) and restored the monastery of Bangor (County Down), but violent disputes about the succession compelled him to go south again to Lismore.

Cellach on his deathbed (1129) tried to persuade Malachy to abandon his monastic retreat and to accept the succession of Armagh, both as abbot and as archbishop, in a way of devolution directly contrary to time-honoured Irish custom, thus to establish the cardinal principle of reform throughout Ireland. Malachy felt that opposition would be too strong just then, but three years later, deferring to the instances of Bishop Malchus and of Gilla Espuic (Gillebertus), bishop of Limerick, he went north to take up his burden. For five years he ruled the diocese and the whole province of Armagh without setting foot in the city, leaving the temporalities to Muirchertach and to Niall, son of Aed, who came after him. At last, in 1137, he had Gilla mac Liag (Gelasius), the abbot of Derry, appointed in his stead at Armagh, and returned to Down.

In 1139 he set out from Ireland to solicit from the pope the pallium for Gilla mac Liag. Innocent II made him papal legate in Ireland, but refused to grant the pallium until it had been unanimously applied for by a "general council of the bishops, clergy and nobles." Malachy took the opportunity to visit Clairvaux and thus began his friendship with St. Bernard. He introduced the Cistercians to Ireland by founding Mellifont (1142). To promote the reform of the Irish dioceses, Malachy also introduced the canons of Arrouaise, who followed the rule of St. Augustine, to serve the cathedrals. On his second journey to Rome to make fresh application for the pallium he died in the arms of St. Bernard at Clairvaux in the night between Nov. 2 and 3, 1148. The object of his life, the establishment of a regular hierarchy, was realized at the council of Kells (1152). He was canonized in 1190 and his feast day is Nov. 3.

No writings of St. Malachy are known to exist, but his name was attached to the Prophecy of the Popes by a 16th-century forger whose sources, though not his motives, have been demonstrated. It consists of a list of mottoes supposed to fit the popes from the mid-12th century to the end of time (the last being Peter II). Up to c. 1590 they allude to the popes' names, places of origin and careers before their election, never to their activities as pontiffs; the remaining mottoes, supposed to predict the future, are vague devices deprived of any connection with historical realities. It was first published (and ascribed to Malachy) by a Belgian Benedictine monk, Arnold Wion, *Lignum vitae*, book ii, ch. 40 (1595), and often reprinted. The critical view is set forth by H. Thurston and by E. Vacandard. An alleged prophecy of St. Malachy on the length of English domination in Ireland and a third on the succession of the kings of Castile are still more modern concoctions.

(Pl. Gn.)

MALACOSTRACA, the largest subclass of Crustacea (*q.v.*), including the shrimps, crabs, lobsters, beach "fleas," sowbugs and their near relatives. Excepting the Leptostraca, they may be defined as Crustacea having the body composed of 19 somites, all typically bearing appendages, the trunk limbs differentiated into two series, a thoracic of eight and an abdominal of six pairs; and the genital openings of the female on the sixth, those of the male on the eighth thoracic somite.

ORIGIN AND RELATIONSHIPS

On the basis of the comparative morphology of the Malacostraca a scheme for the probable course of evolution of the group may be drawn up that is, at least, not contradicted by the scanty knowledge of its fossil representatives. According to this scheme, the earliest Malacostraca exhibited what has been called the "caridoid facies"; that is to say, they were shrimplike in general form, with a carapace enveloping but not coalesced with the thoracic somites; with stalked eyes; two-branched, or biramous, antennules, and a scalelike exopodite on the antenna; with the thoracic limbs forming walking legs having swimming exopodites and branchial epipodites and a tendency for one or more of the anterior pairs to be assimilated to the mouth parts as maxillipeds; and with the abdominal appendages forming biramous swimmerets, except the last pair, which are large, lamellar, and form with the telson a "tail-fan."

The earliest fossils that can be definitely referred to the Malacostraca occur in the Carboniferous rocks and present, with little modification, the caridoid facies described above. Some of them (*Pygocephalus*) have a brood pouch formed by overlapping plates (oostegites) from the bases of the thoracic legs and appear, there-

fore, to be referable to the order Mysidacea. From the caridoid Mysidacea a series can be traced in which the carapace is progressively reduced, the thoracic exopodites are lost and the eyes become sessile. Although paleontology gives no help, the steps of this series are indicated by the specialized offshoots that have given rise to the orders the Cumacea, Thermosbaenacea, Tanaidacea and Isopoda. The Amphipoda belong to the same series but their precise place in it is less clear. The other orders of Malacostraca have no brood pouch and appear to have diverged very early from the primitive stock.

Already in Carboniferous times the Syncarida had lost the carapace and had much the same general structure as the recent *Anaspides* and its allies. Another series in which the carapace coalesced with the thoracic somites gave rise to the great group of the Decapoda, from which the Euphausiacea are perhaps an offshoot. The Decapoda, beginning with caridoid forms, have, in several independent lines, assumed the crablike or "carcinoid facies" by reduction of the abdominal region (Brachyura or true crabs, and crablike Anomura). The Stomatopoda had assumed nearly their typical structure in Jurassic times, but their earlier history is unknown.

This phylogenetic scheme so far has dealt with only certain groups of the series Eumalacostraca. The rest of the malacostracans, belonging to the series Leptostraca, are generally considered primitive, forming a link with the subclass Branchiopoda. They differ from the other Malacostraca in having an additional somite in the abdomen, the telson terminating in a "caudal fork," and a bivalve carapace provided with an adductor muscle. The thoracic limbs are more or less flattened and leaflike and have a general resemblance to the trunk limbs of the Branchiopoda though a close comparison is difficult. The existing genera, *Nebalia* and its allies, are believed to show affinity with the fossil *Ceratiocaridae*, the earliest of which appear in Cambrian rocks and are thus vastly more ancient than any other Malacostraca. Recent work, however, tends to diminish the significance of the differences between the Leptostraca and Eumalacostraca, and, in particular, the recognition of a vestigial seventh abdominal somite in certain primitive Mysidacea suggests that the Leptostraca may be related more closely to the peracaridan malacostracans than has been supposed.

CLASSIFICATION AND SURVEY

The six superorders of Malacostraca assigned to the Leptostraca (1) and to the Eumalacostraca (2-6) are as follows:

Phyllocarida.—This group, the sole superorder under the series Leptostraca, may be characterized in part by a large carapace that is not fused with any of the thoracic somites, by stalked eyes and by an abdomen of seven segments (six in all other Malacostraca). The single order, *Nebaliacea*, includes only three or four living genera, all marine mud burrowers, in part scavengers. They are widely distributed in all seas, usually occurring at moderate depths. Some, such as the large *Nebaliopsis typica*, which attains a length of more than 1½ in., live at depths exceeding 1,000 fathoms. The doubtful affinities of these Leptostraca are mentioned above.

Syncarida.—A small group of fresh- and alkaline-water survivors of crustaceans that lacked a carapace and were more widely distributed in Carboniferous and Permian times. Included are the stalk-eyed mountain shrimp (*Anaspides*) of Tasmania; the sessile-eyed *Koomunga* in the Australian region; and the Bathynellidae minute, blind, subterranean forms from central Europe, Africa, South America, India and some Indo-Pacific islands.

Pancarida.—The Thermosbaenacea are the only order of this superorder. The known species are minute, blind crustaceans, up to several millimetres long, with a carapace covering thoracic segments one to three and forming a dorsal marsupium characteristic of the group. One, *Thermosbaena mirabilis*, is found in Tunisian hot springs (temperature 120° F. or more); a few closely related species of *Monodella* occur in fresh and brackish subterranean waters in Italy and Yugoslavia.

Peracarida.—A carapace, if present, is not fused with more than four thoracic somites; eyes, when present, are stalked

(Mysidacea, stalks movable; Tanaidacea, stalks fixed) or sessile (Cumacea, Isopoda, Amphipoda). The Mysidacea comprise generally small shrimp-like swimming forms, nearly all marine. They are called "opossum" shrimps because of the brood pouch formed of oostegites attached to the coxae of the thoracic legs, in which the young undergo their entire metamorphosis after hatching out as nauplius larvae. Their size range is considerable, running from the tiny *Anchialus pusillus*, $\frac{1}{8}$ in. long, to *Gnathophausia ingens*, which may attain almost 14 in. in length. Probably all serve as the food of other animals. Several species occur in fresh water. One of these is *Mysis relicta*, a widely distributed lake dweller in the northern hemisphere.

The Spelaeogriphacea are cave-dwelling forms scarcely more than half a centimetre long, with club-shaped, movable ocular plates, or lobes, lacking visual elements or pigment. As in other Peracarida the brood pouch or marsupium is ventral. Cumacea are marine mud burrowers but the males are, to some extent, free swimming. Tanaidacea are also part of the microfauna of the sea bottom, less able to swim than the Cumacea.

Isopoda are a very varied and successful group, creeping, mud-burrowing and sometimes actively swimming in the sea and a few in fresh water. The destructive wood-boring crustaceans are principally isopods. The most widely distributed of them in both Atlantic and Pacific oceans, the gribble (*Limnoria lignorum*) is often accompanied by a boring amphipod, *Chelura terebrans*. Next to the molluscan shipworms or teredos, the tiny gribble ($\frac{1}{8}$ to $\frac{1}{2}$ in. long) is the worst known destroyer of submerged timbers. Infested piling may carry 300–400 individuals to the square inch of surface in favoured localities. An untreated test piece of Oregon fir 5 ft. long by 3 in. square, set in Port Jackson, Austr., was 60% destroyed in six months by a combined attack by *Limnoria* and *Chelura*. By the time nine months had elapsed, it was utterly riddled, with the assistance of shipworms that had by this time invaded the timber. Several species of *Sphaeroma*, though larger ($\frac{1}{4}$ in. long, more or less), also attack wood, but not so generally as *Limnoria*, and less in American than in Australian waters. *Sphaeroma quoyana* is reported to have honey-combed claystone or "papa rock" used in harbour works in New Zealand to such an extent that blocks of concrete overlaying it sank several feet.

Parasitism appears in many different families and leads to extremes of specialization and degeneration. One suborder, Oniscoida, consists of the terrestrial, air-breathing wood lice. Creeping and swimming forms of Amphipoda, another varied and successful order, abound in fresh water and in the sea. A few of these sand-hoppers or beach "fleas" may become wholly terrestrial. The vast majority of amphipods belong to one suborder (Gammaridea), that includes both free-living and parasitic forms; members of a smaller suborder (Hyperiidea) are planktonic, occur at times in vast swarms and are consumed in great quantities by seals, cetaceans and other marine animals; a third suborder (Caprellidea) contains the exclusively parasitic family Cyamidae, the whale lice.

Eucarida.—This group is recognized by stalked eyes and the carapace fused dorsally with all thoracic somites. The order Euphausiacea is a small group of planktonic, phosphorescent shrimps, except for a few living in the deep sea at 1,000 fathoms or more. The pelagic, open-sea species are important food of whale-bone whales. The Decapoda, on the other hand, form the most extensive and diversified of all the orders of Crustacea. It includes the largest representatives of the class and, indeed, of all living Arthropoda, and, since many of them are used for food, they are more generally familiar and more thoroughly studied than any other Crustacea. They are classified into two suborders:—Natantia, comprising the shrimps and prawns; and Reptantia, comprising three sections, burrowing shrimps, true and spiny lobsters, crayfishes and their relatives (Macrura); hermit and lithodid crabs, sand bugs and allied forms (Anomura); and true crabs (Brachyura). The headquarters of the group is in the sea but many of its members have invaded fresh waters (river prawns and river crabs in the tropics and crayfishes in temperate regions). Although a few are so far terrestrial as to deserve the name of land crabs, and may—like the coconut or robber crab—even climb

lofty trees, they all pass their young stages in salt or fresh water.

Hoplocarida.—The members of this superorder differ from all other Malacostraca in having the first antennae and the stalked eyes attached to movably articulated segments of the head. The carapace is small and shallow, fused with two or three thoracic somites, leaving four well-developed somites free. Species of the single order Stomatopoda are sometimes known as "mantis" shrimps from the resemblance of their large prehensile claws to those of the mantis insect. They are exclusively marine, burrowing in sand or lurking in crevices in the shallow waters of all the warmer seas. A few go into brackish water. Many species are rare, known only from a few specimens, yet others are found in greater abundance, such as *Squilla investigatoris*, of which 500 were taken in a single haul from 110 fathoms in the Indian ocean.

Despite their vicious claws, they have numerous enemies among the fish and octopuses. They are much used for food in the Mediterranean region, in the Philippines, Malaya and elsewhere. In Japan they are cheaper than other edible crustacea. One of the largest stomatopods on record is a Philippine specimen of *Lysiosquilla maculata*, slightly more than 15 in. in length.

(W. T. C.; W. L. St.)

MÁLAGA, a city of southern Spain in the region of Andalusia, the capital of a province of the same name. It is situated on the Mediterranean in the centre of the Costa del Sol, 140 km. (87 mi.) S.W. of Granada by road. Pop. (1960) 301,048. The Guadalmedina river, which before the construction of the dam at Agujero caused frequent severe flooding, flows through Málaga from north to south, while above the city towers the Monte de Gibralfaro, crowned by an ancient Arab fortress. Sheltered from the north winds by the surrounding sierras, Málaga enjoys a mild climate throughout the year, the temperature almost never falling to the freezing point. Nearby are a number of shallow beaches some of which, e.g., Marbella and Fuengirola, have pine woods reaching to the seashore. The city is a popular centre for water sports.

The main streets of the city are the Calle del Marqués de Larios, with fine marble paving; the Calle de Granada; and the Avenida del Generalísimo Franco. At no. 16 in the Plaza de la Merced is the house where the artist Pablo Picasso was born. The cathedral, in the centre of the old city, was begun in 1528 on the site of a mosque; the interior, main façade and one of the towers were completed in 1782, but the second tower remains unfinished. The choir contains carvings by Pedro de Mena. Other important churches are those of Santísimo Cristo de la Salud, Sagrario and Victoria, the latter being notable for the macabre decorations on the tomb of the Villalcázar de Sirga. The provincial museum of art has a collection of 17th-century masterpieces, as well as modern works including some by Picasso. The Muslim castle, the Alcazaba, has been reconstructed as a museum and garden, but the Gibralfaro fortress remains in its original form.

Málaga is the foremost Spanish port on the Mediterranean after Barcelona. Its harbour can accommodate more than 30 vessels of medium tonnage and it possesses a silo for wheat with a capacity of 4,000 tons and automatic operation. There is a dry dock capable of handling small vessels. The main exports are dried fruit, almonds, iron, olive oil, oranges, lemons, olives, canned anchovies and the famous Málaga sweet wine; principal imports are petroleum, manufactured goods, corn, chemicals, iron and steel. A railway connects Málaga with Granada, Córdoba and other points in Spain. Air services to Madrid operate from Churriana airport 8 km. (5 mi.) S.W. The principal industries of the city are concerned with the manufacture of building materials and foodstuffs.

Málaga was founded by the Phoenicians in the 12th century B.C. It was conquered successively by the Romans and the Visigoths, and was taken by the Moors in 711. Under Muslim rule it became one of the most important cities in Andalusia. When the caliphate of Córdoba disintegrated, the kingdom of Málaga was founded, ruled over by amirs who named it "terrestrial paradise." After several unsuccessful attempts, the Christians took the city on Aug. 14, 1487. It was occupied from 1810 to 1812 by the French. In 1831 it was the scene of an abortive revolutionary attempt by

53 insurgents who landed there from Gibraltar.

MÁLAGA PROVINCE, one of the eight modern subdivisions of Andalusia, is bounded on the west by Cádiz, north by Seville and Córdoba, east by Granada and south by the Mediterranean. Area 7,276 sq.km. (2,809 sq.mi.). Pop. (1960) 775,167. The northern half of the province belongs to the Andalusian plain watered by the Guadalquivir; the southern is mountainous and rises steeply from the coast, along which there is a narrow strip of lowland. The Sierra de Alhama, separating the province from Granada, rises above 5,700 ft.; it continues westward in the Sierra de Abdalagis. Not far from the Cádiz boundary the sierras of Ronda, Mijas, Tolox and Bermeja converge in a summit of nearly 6,500 ft. The principal river is the Guadalhorce, rising in the Sierra de Alhama; the only other considerable stream is the Guadiaro. There is an extensive salt lagoon near the northern boundary. The province is largely agricultural, and fruits, vegetables, olives and grapes are raised along the coastal lowlands and in the rich interior valleys. The vineyards were severely affected by the *Phylloxera* outbreak of 1878. There are considerable mineral resources in the mountains, chiefly iron and lead. Besides Málaga, the most important cities in the province are Ronda, with its 330-ft.-deep gorge separating the old and modern parts of the town, and Antequera, which has in its neighbourhood the famous Menga, Viera and Romeral caves. The almost tropical climate of the coast makes it a popular tourist resort; the district of Torremolinos, 7 mi. (12 km.) S.W. of Málaga, is noted for its beaches. There is a national hunting region in the Serranía de Ronda, 7 mi. (12 km.) from Marbella. (A. C. A.)

MALAGASY REPUBLIC (RÉPUBLIQUE MALGACHE) occupies the island of Madagascar and minor adjacent islands in the Indian ocean off the east coast of Africa. It was a French colony from 1896 to 1946, a territory of the French Union until 1958 and thereafter a member state of the French Community.

Madagascar is one of the largest islands in the world. Its area is 226,657 sq.mi., with a maximum length of 995 mi. and a maxi-

mum width of 360 mi. It lies in the southern hemisphere between latitude 11° 57' and 25° 38' S. and longitude 43° 12' and 50° 17' E. and is thus almost entirely within the tropics; the Tropic of Capricorn crosses the southern end of it. The Mozambique channel separating it from Africa is 248 mi. wide at its narrowest part. Madagascar is surrounded, at a distance of 185 mi. to 560 mi., by small groups of volcanic islets: the Comoro Islands, the Mascarene Islands and the Seychelles (q.v.). This article is divided into the following sections:

PHYSICAL GEOGRAPHY

Geology and Paleontology.—The former hypothesis that the island of Madagascar was at one time part of Gondwanaland (q.v.) an immense continent joining southern Africa to India, is now disputed. It seems probable that a gulf corresponding to the southern part of the Mozambique channel existed from the end of the Paleozoic era and that the subsidences or slow driftings that have brought the island to its present position took place at the beginning of the Mesozoic era. Very ancient Pre-Cambrian foldings have affected an assemblage of paragneissic formations with granitic intrusions. On these formations rest three more recent series, also traversed by granitic intrusions of which the youngest, schists and quartzites, are of the Devonian period; they have been distorted by movements of the Hercynian orogenesis, as is shown by the faults and subsidences that divide up the central massif. The interior of the island has the appearance of a horst to which are opposed the western plateaus with their regular sedimentary layers. From the foot of the hills to the Mozambique channel the strata run from Carboniferous to Middle Jurassic; these formations are called Karroo by analogy with the similar African ones. At the end of the Cretaceous, the sea invaded the east coast for the first time; the advances and withdrawals of the sea occurred from then on in regular succession and different layers accumulated: Upper Jurassic marls, Cretaceous marl-sandstone deposits, Eocene and Miocene limestones that seem to mark the end of marine sedimentation. The Neogene is continental everywhere yellow sands on the west coast, southern clay sheets passing into the Androy sands laterally, lacustrine deposits in the interior. Tertiary movements have only slightly modified the sedimentary layers of the coastal regions, but have on the other hand violently affected the old shelf. Ancient fractures have come together again and new ones have appeared, accompanied by volcanic manifestations everywhere. Cretaceous eruptions showed in basaltic flows. Miocene eruptions in the extreme north, pro-Quaternary eruptions represented by basaltic flows and the recent systems of the Montagne d'Ambre, of the Ankaratra and of the Itasy. Violent earthquakes have often shaken the island and still bear witness to the strength of orogenic forces.

Numerous fossil remains have shown the existence of a whole giant fauna, giant land tortoises and Lemuridae (*Megaladapis* *Archoeindris*) much bigger than the modern species. A giant bird, *Aepyornis*, was perhaps contemporary with the first inhabitants of the island. It was about the size of an ostrich, but it was completely wingless and had enormous feet. Its eggs, whose fossils have been found until recently, were bigger than ostrich eggs. Reptiles also seem to have been very large, e.g., the *Bothriospondylus*.

MAP OF MALAGASY REPUBLIC SHOWING PHYSICAL FEATURES, MAJOR TOWNS AND TRANSPORTATION ROUTES

dylus, related to the *Diplodocus*, which measured more than 66 ft. Finally, traces of fossil fishes whose species have disappeared are very often found in the lacustrine deposits.

Relief and Drainage.—Madagascar consists of three large parallel longitudinal zones: the central plateau formed from ancient systems; a narrow littoral strip to the east; and a zone of sedimentary formations comprising low plateaus and vast plains to the west.

The Plateau.—Between 2,500 and 4,500 ft. the plateau is composed of ancient crystalline and eruptive rocks. It has been several times folded and worn down and is tilted to the west where the slope is less sheer than it is to the east. The whole is covered with a red soil, a lateritic clay resulting from the breakdown of the rocks by rain and heat, which owes its colour to the iron oxide it contains. Where this red soil is covered with humus it bears forests and crops, but where it has been leached it forms a sterile lateritic covering.

Three massifs of the plateau are over 6,500 ft. in height: the Tsaratanana in the north, separated from the rest of the plateau by the ridge of Androva, whose volcanic summit (9,468 ft.) is the highest point on the island; the Ankaratra in the centre, an enormous volcanic mass whose summit, Tsiafajavona, is 8,674 ft. high. The Ankaratra is a watershed separating three basins: the Imerina in the centre of the island where Tananarive (Antananarivo) stands on the Betsimitatra plain; the Itasy with its famous lake of volcanic origin; the Vakinankaratra, full of extinct volcanoes and hot springs. Farther south, the Andringitra, a vast granitic massif, dominates the Betsileo district. The plateau slopes more regularly toward the extreme southern plain but its boundaries to east and west are more abrupt. To the east it descends in a sharp fault by steps of 1 to 200 ft. This cliff, called the Great cliff or Cliff of Angavo, is often impassable and is itself bordered by an escarpment (Betsimisaraka) that overhangs the coastal plain. Behind the scarp face are the remains of ancient lakes (Alaotra). To the south the two steep gradients meet forming the plateaus of the Mahafaly and the Androy, which in most places overhang the sea in precipitous cliffs. Toward the west, on the other hand, the descent is made in a series of steps, like the Tampoketsa which leads to the plains of Majunga or the plateaus of the Isalo. Sometimes, however, the plateau is bordered by an escarpment, less high than that of the east but still impassable (Cliff of Bongolava). Finally, to the extreme north, the plateau is separated by the low sedimentary belt of the Ambre massif, which includes a series of volcanic craters.

The Eastern Coastal Zone.—This zone has an average width of 30 mi., and is a narrow alluvial plain terminating at the sea in a low coast line bordered with extensive lagoons linked together by the Canal des Pangalanes. To the south of Farafangana, the coast becomes rocky but still inhospitable, and it is only in the southeastern tip of the island that there are little bays. There, at Sainte Luce and Fort-Dauphin, were the first French settlements.

The Western Zone.—This is everywhere broader, being from 62 mi. to 124 mi. wide. Its sedimentary layers slope toward the Mozambique channel and produce a succession of hills, especially in the Sakalava country. One side of these steep hills dominates the hollows formed in the soft sediments, while the other descends to the sea in rocky slopes (Borna-Bamaraha). The coast itself is straight, bordered by small dunes and fringed with mangroves. The currents in the Mozambique channel have favoured the deposit of alluvium and the growth of deltas. On the north-western coast there are estuaries and bays (Diégo-Suarez). This coast is bordered by coral reefs and volcanic islands like that of Nosy Be which protects the bay of Ampasindava.

The hydrography of the island is also to be explained by the asymmetry of its relief. The rivers of the east are short, turbulent and have an abundant flow. They discharge either into the lagoons through sandy mouths which are constantly shifting, or directly onto the coast with rapids and waterfalls. These are the rivers Maningory (whose source is Lake Alaotra), Loky, Bemarivo and the northern Mananara in the northeast; the Ivondro, Mananary Faraony, Manatsatrana rivers in the east. The most impor-

PLATEAU LANDSCAPE NEAR TANANARIVE (ANTANANARIVO)

tant rivers are those which have captured plateau streams: the Mangoro, in the centre, which drains part of the intermediate slope and receives the Onive from the plateau; and the southern Mananara, which receives two tributaries from the slope and one from the plateau. The western rivers are much longer, regular and often navigable over long stretches, but they carry masses of alluvium which block their estuaries. The chief are the Sofia; the Betsiboka, which is in Tananarive province and navigable for over 150 mi.; the Tsiribihina, formed by three rivers of which two come from the plateau; the Mangoky, which ends in a huge delta; and the Onilahy, which flows through arid country and has a less abundant flow (it has a well-sheltered estuary to the south of Tulear).

All these rivers are very important, not only for navigation but because, intersected by dams, they can provide power and water for irrigation of crops. There are numerous lakes of volcanic origin (Itasy, to the west of the Ankaratra, Titiriva near Antsirabé). Lake Alaotra is the last survivor of the immense lakes that once occupied the eastern slope. To the southwest Lake Tsimanampetsotsa is a salt lake covering 74 sq. mi. without outlet.

Climate.—The individuality of Madagascar's climate is explained essentially by the asymmetry of the relief and the winds. The plateau forms a permanent obstacle to the winds and is the major factor in the differentiation of the climatic regions.

The winds are of three kinds: sea breezes, trade winds and monsoons. The sea breezes have only a local effect in cooling the shores, and their influence is hardly felt inland. The trade is the dominant wind. Caused by the anticyclone situated over the Indian ocean between Madagascar and Australia, it blows from the southeast almost continuously, but is particularly violent during the southern winter (May to September). The east coast is thus to windward and has a high rainfall (139 in. per year at Maroantsétra in Antongil bay). But once past the Cliff of Angavo and over the plateau, the trade wind loses its humidity and behaves like a föhn; it does not bring rain to the Sakalava country, which receives its rainfall from the monsoon. The latter is most noticeable during the southern summer (October–April) when the sun is near its zenith. It comes from the north as a continuation of the Indian monsoon but produces northwesterly winds because of deviation (Majunga has a rainfall of 64 in. from November to April, and an annual total of 65 in.). The southwest receives scarcely any rainfall, except from occasional storms, and so is a semidesert region. The central plateau enjoys a tropical

mountain climate with well differentiated thermal seasons (at Antananarivo the hot season lasts five months, the cool season seven) and there are 53.5 in. of rainfall, of which only 4 in. occurs during the six winter months. Lastly, the influence of the cyclones must be noted as they devastate the island periodically. Madagascar lies in the path of the southwestern cyclones of the Indian ocean, and Tamatave is one of the most exposed places.

Vegetation.—The vegetation zones are likewise longitudinal. The screw pines and palms of the east coast dunes are succeeded inland by the reeds of the lagoons and by the *viha*, a kind of wide-leaved arum which grows in the marshes, and, on the low hills, by scrub. Most of the swamps have been turned into rice fields and the slopes have been planted. Toward the escarpment the vegetation becomes more dense: the *savoka* is sometimes formed by scrub (*Longozo*, *Haronga*, *Citrus*) and sometimes by a denser brushwood (*Ravenala*, the traveler's-tree, with giant leaves at the top of a smooth trunk; *sevabe* and *dingadinga*, varieties of bamboo), but it is never suitable for timber. The true forest (*ala*) is higher up though it now covers only a small area (about 7% of the island). It consists of small, thin trees 65–80 ft. high and of varied kinds. At their base grow ferns, dwarf palms and grasses; there are also numerous lianas and epiphytes. The plateau is an area of grassland, and there are no trees except round the villages. The grasses are mostly burned by the cattle raisers and gradually disappear allowing the red earth to be seen. In the plains of the west the grassland gives place to savanna: the grasses, which are taller, are scattered with fire resisting trees like the *satrana*, a large variety of palm. The savanna, which produces a very monotonous countryside, is tending to spread into the Sakalava country and into the forest of deciduous trees that formerly wooded the whole west of the island. On the western plateaus, however, there remain the baobab trees and in the lower parts the raffia palm.

In the north and northeast (Montagne d'Ambre, Tsaratanana, Nosy Be) the vegetation is the same as in the east, *savoka* (secondary forest) tending to replace the original forest. By contrast, the Androy region in the extreme south is characteristic. It is the region of Karroo scrub, with spiny succulents. A great number of the plants in the island are unique and many are in danger of becoming extinct through constant burning.

Animal Life.—The unique form of Madagascar animal life is equally remarkable. At first, the island had no monkeys, deer or snakes. It has, nevertheless, three-quarters of the known Lemnidae of the world; about 40 species are found there, including the *Indri*, 39 in. high (eastern forests, around Tamatave and Antongil bay) and the *Microcebus*, the size of a fist. *Propithecus* is found in the south and east and it has been possible to tame other species of lemur like the maki and the varika.

The nocturnal aye-aye (*Daubentonia madagascariensis*) is a species peculiar to Madagascar. Other vertebrates include many kinds of hedgehogs, bats, civet cats and rodents. Birds are very numerous: guinea fowl (*akanga*), partridge, pigeons, herons, ibis, flamingoes, egrets, owls, birds of prey (*papango*, *voromahery*). Crocodiles are found in all waters, except in the coldest parts of the plateaus.

Various land and sea tortoises are found, chameleons of all sizes, geckos, lizards, snakes, including the *do*, which is 10–13 ft. long but is harmless. There are few fresh-water fish, but marine fish and crustaceans abound on the coasts and in the lagoons. Certain species are peculiar to the island, like the globe fish, bristling with spines, and the cofferfish. Insects abound: grasshoppers, termites, cockroaches, all sorts of mosquitoes (some of which attack cattle), the Madagascar *Bombyx* (moth) which gives a valuable silk and more than 800 species of butterfly. Man has imported domestic animals: the zebu, which has great importance in Madagascan life, the fat-tailed sheep, dogs, poultry and pigs, these last being mostly raised by Europeans.

(J. D.)

THE PEOPLE

The people of Madagascar, collectively known as Malagasy (in French Malgache), appear to be a mixture from very ancient times of Indonesians and Africans who arrived there by sea at various

periods. The majority exhibit a blend of Indonesian and African characteristics. In general one can distinguish 18 peoples who correspond to geographical regions or to kingdoms no longer existent. The principal peoples are as follows: (1) In the east the Betsimisaraka ("the inseparable multitude"); the Antemoro, of whom the noble orders claim Arab descent and who use Arab script; the Tanala ("people of the forest"); the Antesaka (Antaisaka); and the Antanosy. These peoples are in general of medium stature and dark. (2) On the plateau the Merina (*q.m.*), around Tananarive, of whom the higher castes, the nobles (Andriana) and the bourgeois class (Hova) are often of an almost pure Indonesian type; the Betsileo (around Fianarantsoa); the Sihanaka around Lake Alaotra; to the north the Tsimihety; to the south the Bara who are tall and of African type. (3) In the west the Sakalava; the Vezo, who are fishermen; the Mahafaly and the Antandroy ("people of the brambles"), who inhabit the dry southern region; and some Makoa, who came from Africa, often as slaves, and are distributed among the Sakalava.

Language.—The Malagasy language belongs to an Indonesian group, with some peculiarities of its own such as the vocalization of final letters, the existence of a definite article and the "relative" mood of verbs. It contains some words of Bantu, Swahili, Arab, English and French origin. The existence of dialects, involving changes in certain consonants and final letters and some differences in vocabulary, does not affect the basic unity of the language.

From 1820 the Merina dialect, written in Latin characters, has become the official language. In this the letter *o* is pronounced as French *ou* (English *oo*); final *a* and *y* are almost silent. Malagasy literature includes proverbs, orations, stories, folk tales and poems. The soft and musical quality of the language has earned it the title of "the Italian of the Indian ocean."

Religion.—The traditional religion is founded on ancestor worship. The dead are mostly buried in stone tombs, by family or clan, and are believed to keep watch over the living and to reward or punish them according to their deserts. They are invoked, either on special occasions of illness or disaster, or in special ceremonies such as the festival of the dead in the southeast and the Famadihana, "festival of returning," when the dead are moved from one tomb to another, on the plateau. The supreme being, called Zanahary, "the Creator," or Andriamanitra, "the Fragrant One," stands above the dead in the divine hierarchy and is associated with them in the ceremonies. There is also a belief in invisible beings who inhabit trees and stones, in water spirits

EDITIONS HOA-QUI

CARVED WOOD GRAVE MARKERS OF THE MAHAFALY TRIBE, TULEAR DISTRICT
MALAGASY REPUBLIC

and in certain animals as ancestors or kin. Divination is employed, based mainly on *sikidy*, akin to Arab geomancy. The mass of taboos (*fady*), imposed either by custom, by the date of birth or by sorcerers, fill the life of the Malagasy with inhibitions, and there is also the fear of spellbinders.

Formerly various kinds of trial by ordeal were practised in order to discover spellbinders and criminals. Notable among these was the tanghin poison ordeal. Now almost half of the people, especially among the Merina and the Betsileo and in the towns, have been converted to Christianity about equally divided between Protestant and Catholic. In the northwest there are about 70,000 Muslims.

Social Customs.—The traditional Malagasy family is patrilineal and includes collateral branches. The title of father and mother is given to all the elders, and that of children to all the younger generation. The clan (*foko*) includes families of the same origin. The *fokon'olona* is that part of a clan which lives in the same village and whose decisions are taken by the heads of its families. This patriarchal system is on the decline in the Christian areas and in the towns, but respect for elders persists. The artificial relationship of blood brotherhood between two persons can be created by a special ceremony. Malagasy society is divided into castes, which are in most cases limited to three: nobles, freemen and former slaves. Intermarriage between the castes is prohibited in principle. Polygamy has disappeared in the Christian areas. Marriage involves various ceremonies: a delegation to the prospective bride's family, sacrifices, the carrying off of the bride, etc. Children are always desired and the chief fear of women is sterility. Adoption is easy and is frequently undertaken.

The Malagasy house is always rectangular with the long sides running from north to south, the door on the west and an acutely angled roof. The materials vary with the region: clay is used in the central area, wood and branches on the coasts. On the east coast the houses are built on piles or stilts. Clothing consisted formerly of the loincloth (of bark or cotton), the sheath dress (of rush matting or raffia) and the *lamba*, a kind of toga made of cotton or silk. These are giving way increasingly to imported clothing and materials. Traditional art, which is much less rich than that of Africa, comprises wooden statues, rush matting and coloured baskets, and decorated plates and spoons. Musical instruments betray especially African or Indonesian ancestry; notable is the *valiha*, a kind of zither made from bamboo. The same is true of the traditional dances that still accompany certain festivals. A love of music and poetry is a characteristic of the Malagasy.

HISTORY

The island was certainly inhabited during the Iron Age by Indonesian and African navigators. For many centuries the Malagasy have been divided into a number of peoples, separated from one another by a wide extent of uninhabited country.

The Indian ocean was frequented during the early middle ages by Indonesians and the Indians, who left traces in the population of Madagascar. From the 9th century the "Arabs" (correctly, Muslims of diverse origins), already established on the east coast of Africa and on the Comoro Islands, formed settlements on both the northwest and southeast coasts of the island. In the southeast they became merged in the general mass of the people, especially among the Antemoro. In the northwest were several large "Arab" colonies, which occupied the ports of Anorotsangana, Mojanga (Majunga) and several others, retaining their distinct nationality.

Early European Connections.—The Alexandrian geographer Ptolemy speaks of an island called Menuthias, which might be Madagascar. Marco Polo has a chapter upon "Madeigascar," but his accounts of it are confused with those of the mainland of Africa, even the name later adopted for the island being a misunderstanding of that of the mainland port of Mogadishu.

The first European voyager to see the island was a Portuguese named Diogo Dias, captain of one of the ships of a fleet bound for India. Separated from his companions by a storm near the

Cape of Good Hope, he sighted the eastern coast of the island on Aug. 10, 1500. That day being the feast of St. Lawrence, Madagascar was named the "Isle of St. Lawrence." Portuguese missionaries between 1600 and 1619 made unsuccessful efforts to convert the tribes on the southeast and western coasts. In the time of Charles I unsuccessful attempts were made to form English settlements in the southwest and on the island of Nosy Be. From 1642 the French held the extreme southeast point of the island at Fort-Dauphin, and the governor, Étienne de Flacourt, gave the first substantial description of the island. But in 1674 the garrison was partly massacred and partly evacuated. The king of France, however, maintained his claims to the sovereignty of the whole island.

In the late 17th and early 18th centuries Madagascar was the haunt of many pirates, including John Avery, Captain Misson and William Kidd. Between 1768 and 1786 two fresh attempts at settlement were made by the French, one by the comte de Modave at Fort-Dauphin and the other by D'Aladar de Benyowski at Antongil bay. In 1750 the island of Sainte Marie became French. In 1803 Sylvain Roux set up a French agency at Tamatave, which was occupied by the English in 1811.

The First Kingdoms.—Trade in arms and slaves allowed the development of Malagasy kingdoms. At the beginning of the 17th century the most important, those of the Antemoro, Antesaka, Betsileo and Merina (Hova), were still confined to small areas, the last named to the neighbourhood of Tananarive. In that century a southern Sakalava chief, Andriandahifotsi, conquered all the western plains, and his son conquered the northwest (Boina) and the extreme north. The Sakalava dominions, held by descendants of the founder, occupied half the island, but they disintegrated in the 18th century. In this century the half-caste Ratsimilaho (son of an English pirate) set up the kingdom of Betsimisaraka, which very soon disappeared. At the end of the 18th century the disunited Merina kingdom was unified by the great king Andrianampoinimerina (1787-1810). Imerina was soundly organized and the Sakalava incursions checked. Turning his attention to expansion, the king brought the Betsileo into subjection. At his death he bequeathed to his son Radama a single political ambition: "The sea will be the boundary of my ricefield" (i.e., of his kingdom).

Merina Rule.—Radama I (1810-28) was a shrewd and enterprising man. He was helped by the British governor of Mauritius, Sir Robert Farquhar, who, failing to obtain the backing of the British government to replace the French in Madagascar, adopted a policy of supporting the Merina. Radama saw that his people must be educated and civilized, and, making a treaty with Farquhar to abolish the export of slaves, he received in compensation an annual subsidy of arms, ammunition and uniforms, as well as British training for his troops. He was thus enabled to establish his authority over a large part of the island. For some years a British agent, James Hastie, resided at Radama's court. During the same period (1820) Christian teaching was begun in the capital by the London Missionary society. The language was reduced to a systematic written form, and the art of printing introduced; the Scriptures were translated and many schools were formed.

The bright prospects thus opening up were clouded by the death of Radama at the age of 36 and the seizure of the royal authority by his first wife, Queen Ranavalona I. She looked with much suspicion upon the European ideas then gaining ground. In 1835 the Christian religion was declared illegal. Of the Christian Malagasy about 200 suffered death, while many hundreds were punished by fine, degradation, imprisonment and slavery. A few Europeans remained in Madagascar, notably the Frenchman Jean Laborde, who introduced many industries and was influential with the queen. During the queen's rule there were frequent rebellions and distant provinces were desolated by barbarous wars; for some years all Europeans were excluded, and foreign commerce almost ceased. An ill-managed attack upon Tamatave in 1845 by a combined British and French force ended in failure.

This reign of terror was brought to an end in 1861 by the death of the queen and the accession of her son, Radama II. He opened up the kingdom to Europeans, and signed a concession, giving great

powers to a French company. But his weakness soon brought an end to his reign and his life. He was put to death in his palace (1863) and his wife Rasoherina was placed on the throne. The new sovereign refused to ratify the agreement with the French company, but treaties were concluded with the British, French and United States governments. Besides the London Missionary society; other Christian agencies were permitted to work, including the Jesuits and the Anglicans, the Society of Friends and the Norwegian Lutherans. The French explorer Alfred Grandidier explored the island and brought back much scientific information.

At the death of Rasoherina in 1868, she was succeeded by her cousin, Ranavalona II. One of the first acts of the new queen was the public recognition of Christianity; and soon afterward she and her husband, the prime minister, were baptized, the Merina in general soon putting themselves under Christian instruction. Ranavalona II, her predecessor and her successor were in turn married to the prime minister, Rainilaiarivony, who became virtual ruler of the country. Many measures tending to improve the administration were introduced. The Merina then ruled the central part of the plateau directly; the kingdoms of the east and north-east were vassals; but the south and part of the west were independent. The Merina army, well organized under Radama I, had since declined and Merina expansion had consequently ceased.

Revenue was derived from customs, duties, fines and from a money offering, called *hasina*, presented on a great variety of occasions to the sovereign. The government also claimed the unpaid services of the community for public work. Consuls appointed by the British, French and U.S. governments were accredited to the Malagasy sovereign.

Relations With the French.—Although Merina rule would have satisfied British interests in the island, it was otherwise with the French. The tradition of their former settlements and influence was strong; in 1840 they had taken under their protection the Sakalava ruler of the northwest coast. But a treaty concluded in 1868, while establishing French consular jurisdiction, recognized Ranavalona II as queen of Madagascar. A change came under the third republic. The French government revived its claim to a protectorate over the Sakalava of the northwest coast, and in 1883, following Malagasy rejection of French demands, Tamatave was bombarded and occupied by marines. By a treaty signed on Dec. 17, 1885, it was agreed that the foreign relations of Madagascar should be directed by France; that a resident should live at the capital; and that Diégo-Suarez bay, together with surrounding territory, should be ceded to France. Queen Ranavalona II had died on July 13, 1883, and had been succeeded by her cousin Ranavalona III. In 1890 the British government, in return for concessions in Zanzibar, consented to recognize a French protectorate over Madagascar, but Rainilaiarivony, continued to arm and train, with the help of British officers, a large body of native troops. Toward the close of 1894, the French government sent an ultimatum and war followed. An expeditionary force under Gen. J. C. Duchesne landed at Majunga and met with no effectual resistance. On Sept. 30, 1895, the French forces reached Tananarive, and on the evening of the same day the French entered the capital. The protectorate was established. Early in 1896, however, a serious rebellion broke out in several parts of Imerina. This movement was not only anti-French but also anti-Christian. Gen. J. S. Gallieni was sent out to relieve the then resident general.

French Rule and Independence.—Gallieni abolished royalty; Madagascar had already been declared a colony of France. Queen Ranavalona III was exiled to Réunion and subsequently to Algeria, where she died in 1917. Meanwhile, by 1898, the authority of France had been established throughout the island. Gallieni, whose firm and vigorous administration and desire to treat the Malagasy justly made him respected, retired in 1905. In accordance with the usual French colonial system the tribes were all placed under the direct control of French officials, but large numbers of natives were employed in the French administration, and a few Malagasy who became thoroughly assimilated were given French citizenship.

Notwithstanding these measures the growth of a sense of Malagasy nationality could be discerned among the Merina. During World War I a secret society, the V.V.S., was discovered. Madagascar enjoyed considerable economic development during the governorships general of Marcel Olivier (1924-30) and Léon Cayla (1930-40). World War II brought economic crisis with the cessation of exports. The island declared for the Vichy government in 1940, and to prevent its invasion by the Japanese it was occupied in 1942 by the British, who handed it over to the Free French authorities in 1943. It had been considerably disturbed by these events. In 1946, all the Malagasy had been granted French citizenship; but in 1947 a nationalist rising took place on the east coast. Subsequently new political institutions (in particular, local assemblies) were established without difficulty. On Oct. 14, 1958, the congress of the elected assemblies proclaimed an autonomous republic within the French Community and Philibert Tsiranana, a Tsimihety, was elected president. In June 1960 the Malagasy Republic gained complete independence while remaining a member of the Community.

In March 1961 President Tsiranana presided over a conference of 12 states at Yaoundé, Cameroon, where the formation of a Union Africaine et Malgache was announced. A conference of ten African states at Antananarivo the following September confirmed this decision to strengthen mutual ties and a charter which aimed at political co-ordination, economic co-operation and joint defense was established. This project was advanced by the subsequent conferences at Monrovia, Liberia (May 1961), and Lagos, Nigeria (Jan. 1962). The latter was attended by the heads or representatives of 19 states.

In the March 1965 presidential election President Tsiranana won a new seven-year term; later in the year his party, the Parti Social Démocrate, gained 104 out of 107 seats in the national assembly.

POPULATION

The population of Madagascar at the first census in 1900 was 2,500,000; in 1956, 4,934,375; and by the early 1960s exceeded 6,000,000. Increase is at the rate of more than 100,000 a year. The average density exceeds 23 to the square mile; in the rice-growing regions of the east coast and the alluvial valleys and lake basins of the plateau it exceeds 77 but is less than 13 in the pastoral west and the forest-covered cliff regions. The most numerous peoples are the Merina (1,600,000), the Betsimisaraka (900,000) and the Betsileo (700,000). The population other than Malagasy is less than 105,000, including 42,000 French, 14,000 Indians and 8,000 Chinese. The number of Comorans (about 34,000) is increasing on the northwest coast.

The people are essentially peasants. The capital is Antananarivo (*q.v.*; pop. [1963 est.] 298,813), which stands on a steep hill jutting into the surrounding rice fields. There are four towns with a population of 30,000 to 51,000: Tamatave, Majunga, Diégo-Suarez and Fianarantsoa (*qq.v.*). The other principal centres, each with 10,000 to 30,000 inhabitants, are Antsirabé, Tulear, Manakam, Mananjary and Fort-Dauphin. Internal migrations brought the rice cultivators of the southeast (Antesaka) and those of the plateau (Merina and Betsileo) to the almost empty plains of the west which they put under cultivation. This Malagasy "far west" already has an immigrant population greater than the Sakalava. The Tsimihety have expanded in all directions. Some Antandroy to escape from the famines of the extreme south, find paid employment all over the island. There is a large proportion of Merina in the towns, where they are merchants or officials.

ADMINISTRATION

The constitution of the Malagasy Republic, which became law on April 29, 1959, established a presidential regime. The president is elected for seven years and is also the head of state. The parliament comprises a national assembly elected for five years by universal suffrage (male and female) and a senate representing national organizations; two-thirds of the senators are nominated by the provincial councils general. The dominant political party is the Parti Social Démocrate which holds an overwhelming ma-

jority of seats in both the senate and national assembly. The Malagasy Republic is represented in France by a *haut représentant* and in certain other countries by ambassadors.

The republic is divided into six provinces: Diégo-Suarez, Majunga, Tamatave, Tananarive, Fianarantsoa and Tuléar. The provinces, which have a large measure of financial autonomy, are themselves divided into districts and communes (formerly cantons) varying in number, which are administrative units. Large towns have elected municipal councils. Rural communes constitute centres of economic advancement. Many French officials are employed in the central and provincial services. Medical services in the early 1960s included 10 hospitals and about 390 medical centres and infirmaries. The fight against endemic diseases has succeeded in removing the plague and reducing malaria.

About half the children of school age (more than 425,000) attend public or private schools. There are eight *lycées* and institutes of scientific research and agriculture. A university was founded in Antananarivo in 1961. Education is conducted in Malagasy and French.

THE ECONOMY

The traditional economy is based principally on the cultivation of rice and the raising of oxen. The rice fields are of Asiatic type with water levels and embankments. The grazing of oxen often takes the place of cultivation. Food consists of millet (in the south), cassava, potatoes, taro or coco, beans and some fruits (bananas, guavas and mangoes), together with fish from the streams, *brèdes* (a green vegetable similar to spinach) and berries and wild roots. The zebu (humped ox) is used both for tillage and for sacrifice, the beef being eaten during the ceremonies, and it provides visible capital. Poultry is abundant in all the villages. This subsistence economy has been changing during the 20th century through the opening up of the island to world commerce. The traditional products have been improved and new products created. Rubber is no longer cultivated but wax from wild bees is gathered. Scientific study has been devoted to fishery, especially that of tunny, prawns, mullet and whales. The forests have had to be protected and replanting has altered the denuded appearance of the plateau. Raffia fibre is a product peculiar to the island.

The rice-growing area has been doubled. Rice is grown mostly for local requirements but some special varieties of high quality (such as the long *vary lava*) have been developed for export. The American rices of the Carolinas had their origin in Madagascar. Cassava meal and tapioca are prepared from manioc (*Manihot*). "Cape pea," a kind of large haricot grown in the southwest, is exported to England.

Robusta coffee is the chief product of the east coast and the most important item of exported produce. The Malagasy Republic is the world's chief producer of vanilla and ranks second for cloves (east coast). Perfume plants, peanuts (Lake Alaotra), "Maryland" tobacco (west and plateau), sugar (northwest), sisal (extreme south), potatoes (plateau) are substantial items.

There are more than 6,000,000 head of zebu cattle on the natural pastures of the west and the plateau. Pigs are raised in the centre, sheep and Angora goats in the south.

The main resources are graphite, mica and phosphates. A seam of coal in the southwest (Sakoa) has not been worked. There are some uranium and thorium deposits in the southern part of the island, and precious stones (beryl, amethyst and garnet) are found.

The main industries are agricultural and chief among these are rice husking, the manufacture of starch from manioc, sugar refining, tobacco curing, meat preserving and tanning. Cotton is woven and soap and cement are produced locally. There is abundant water power, but the two main barrages on the Mandraka and Tsiazompaniry rivers supply electricity chiefly to Antananarivo. Nine-tenths of the inhabitants live by agriculture and the variety of products avoids serious food crises. Most of the peasants are owner-farmers. Europeans own some plantations (sugar, tobacco and sisal), sawmills and mines. The trade-union movement is widespread in the towns and the two largest organizations are the Confédération Chrétienne des Syndicats Malgaches and the Union

des Syndicats des Travailleurs de Madagascar.

The distance of the main markets of the world is a handicap to Malagasy exports because of the high cost of freight. The lack of domestic industry necessitates the importation of most manufactured goods. Wholesale trade is principally the care of French companies and retail trade is, to a large extent, in the hands of Indians and Chinese. The chief exports are coffee, rice, cloves, tobacco, vanilla, sugar, dried vegetables, raffia and preserves. Of secondary importance are graphite, perfumed oils, sisal, manioc starch and hides. Coffee represents about half the total value. About two-thirds of the exports are bought by France and one-sixth by the United States. Principal imports include materials and clothing, motor vehicles, petroleum products, machinery, iron, tools and cement; approximately two-thirds of these come from France.

Revenue is derived mainly from direct taxation that includes poll and land taxes and taxes on houses and cattle, and indirect taxes such as those from customs, markets, posts and telegraphs.

In former times all transport was on foot; important personages were carried by *filanzone* (palanquin) and goods were slung at the two ends of a pole across the shoulders. Roads have now been constructed all over the country; they are mostly simple tracks suitable for motor traffic but subject to seasonal interruptions. The principal centres are linked by asphalt roads. The total mileage of roads is about 20,000. Two railways cross the cliffs to link the plateau with the east coast: the Tananarive-Côte Est (T.C.E.) to Tamatave, about 230 mi., and the Fianarantsoa-Côte Est (F.C.E.) to Manakara, about 102 mi. The former has branches to Lake Alaotra and to Antsirabé. The island has about 1,550 mi. of navigable rivers supplemented by the Canal des Pangalanes. The latter forms a 403-mi. waterway comprised of lagoons that are strung along the east coast and protected by a line of coastal sand dunes. Sandy or rocky bars (*pangalanes*) are cut at several points to permit the passage of large barges.

The chief port is Tamatave, which has equipment and quay berths. Diégo-Suarez, which has one of the finest roadsteads in the world, is unfortunately too remote from the centre. Majunga has only a lighterage port. Minor ports are Manakara, Fort-Dauphin, Tuléar, Morondava, Analalava and Vohémar. The principal airport is Arivonimano, 32 mi. W. of Antananarivo. Secondary airfields are numerous and local airlines provide daily services.

The government-controlled Radiodiffusion Nationale Malgache at Antananarivo broadcasts in French and Malagasy.

MALAKAND, a Northwest Frontier agency of the Peshawar division of West Pakistan, administered by a political agent residing in the town of the same name, 41 mi. N.N.E. of Peshawar. Pop. (1961) 1,536,766; area 12,344 sq.mi. The agency includes the former princely states of Chitral, Swat and Dir (*qq.v.*), Kalam, the Malakand protected area (Swat Ranizai), Sam Ranizai, and Bajaur and Utmankhel. At Malakand is a 20,000-kw. hydroelectric power station, opened in 1938. The Malakand pass connects the Mardan and Peshawar districts with the Swat valley.

(K. S. AD.)

MALALAS, JOHN (c. 491-c. 578), was a Byzantine chronicler of Syrian origin (*melel* is the Syrian for the Greek *rhētor*). His *Chronographia* in 18 books beginning with the Creation continued certainly to 565, perhaps to 574, but in its extant form it ends in 563. The greater part of it stresses the importance of Antioch

(where Malalas may have been born) and has a monophysite flavour. The last part of book 18 appears to have been produced later, perhaps in Constantinople. It was written in the popular language for unlearned Christian circles, and although often inaccurate and uncritical it is of some value as a source for the first half of the 6th century. It was much used and was translated into Slavonic. Some scholars identify John Malalas with John III Scholasticus, patriarch of Constantinople 565–577, who had earlier been a lawyer in Antioch.

MALAN, DANIEL FRANÇOIS (1874–1959), prime minister of South Africa, remembered as the man who established Afrikaner political control over the Union and used it to initiate the policy of racial segregation known as apartheid and pave the way for a South African republic, was born on a farm near Riebeeck West, Cape colony, on May 22, 1874. He was educated at the Riebeeck-West school, Victoria college, Stellenbosch, and the University of Utrecht, Neth. Returning to South Africa in 1905, he became a minister of the Dutch Reformed Church and also took an active part in the Afrikaans language movement. The Boer rebellion quickened his interest in politics and in July 1915 he left his pulpit to become editor of *Die Burger*, a Cape Town newspaper, founded to support J. B. M. Hertzog's Nationalist party.

Malan presided at the first Cape Province congress of that party later in 1915. He entered parliament in 1918 and in 1919 he was a member of the deputation that went to Versailles to ask for republican independence for South Africa. As a member of Hertzog's cabinets from 1924 to 1933, Malan was responsible for the laws that created a South African nationality and flag and that made Afrikaans an official language of the Union (previously English and Dutch had been recognized), and for the Cape Town agreement concerning the status of Indians in the Union.

When the Nationalist and South African parties fused into the United party in 1934, Malan broke with Hertzog and became the leader of a "purified" Nationalist party which, though small, was the official opposition. The defeat of Hertzog's neutrality motion, which Malan supported, the formation of Jan Smuts' government, and South Africa's entry into World War II, led to a political splintering of Afrikanerdom. Doggedly, patiently and with great skill Malan welded together a "reunited" Nationalist party, which obtained 43 seats in the 1943 election and, in alliance with N. C. Havenga's Afrikaner party, won a narrow majority in 1948. This enabled Malan, aged 74, to form the first exclusively Afrikaner government of the Union.

The primary concern of this government was to implement the policy of apartheid. One of these acts, to give Coloured voters separate and fixed representation, was declared invalid by the supreme court in 1952; the crisis was still unresolved when, after increasing his majority in the 1953 general election, Malan retired in 1954. He died at his home at Stellenbosch on Feb. 7, 1959.

MALANG, the name of a *kabupaten* (regency) in the province of Djawa-Timur (East Java), Indonesia, and of its administrative headquarters. Malang town is situated at an altitude of 1,460 ft. at the foot of the Semeru mountains, 50 mi. S. of Surabaya. Pop. (1961) 341,452 (municipality). At the end of Djalan Kajutangan, the town's busiest street, is the building that formerly housed the Komite Nasional Indonesia Pusat (parliament), which had its first session in Feb. 1947 and was burned down during the revolution. In front of the town hall is the public park with a Freedom memorial in the centre. Industries include the manufacture of cigarettes, ceramics and soap. Malang is connected by road and rail with Surabaya.

Malang has an ancient history, and in the surrounding area are ruins of palaces of the kings of Dinojo, Tumapel and Singosari

(see **JAVA: History**), which attract many tourists. Under the Dutch it became a municipality and a garrison town in 1914, and its modern growth dates from that time. In 1939 the Dutch military headquarters was transferred to Malang, which after independence became the headquarters of the 5th division of the Indonesian army. The Indonesian air force base, Abdurrachman Saleh, is 8 mi. E. of the town.

Malang *kabupaten* was formed after the republic was established. Area 3,413 sq.mi. (8,840 sq.km.). Pop. (1961) 1,474,106. Under the Dutch this was the name of a residency (earlier named Pasuruan) with an area of 3,413 sq.mi. The main occupation of its inhabitants is agriculture, principal products being vegetables, fruits and flowers.

MALANJE (MALANGE), a north central district of the Portuguese overseas province of Angola in west Africa and the name of its capital town. The district had a population in 1960 of 452,285. Area 44,039 sq.mi. Administratively it consists of the *concelhos* (counties) of Malanje, Cacusso and Duque de Bragança and the circumscriptions of Songo, Cambo, Bondo and Bângala. Stock raising (mainly goats) and cultivation are carried on, the chief products being cotton, maize (corn), oil fruits and oil nuts, cassava, sisal and tobacco. The district supplies Luanda with fruit and vegetables. Mineral resources include manganese. The town of Malanje lies on the central Angolan plateau. Pop. (1960) 25,766. It has a Roman Catholic cathedral, beautiful public gardens and several hotels. Tourist attractions include the Duque de Bragança falls (330 ft.) on the Lucala river, other neighbouring waterfalls and the Pungo Andongo black stones, gigantic black monoliths associated with the story of the native queen Ginga. Malanje is linked with the provincial capital, Luanda, on the coast, by road and also by rail (280 mi.). Eastward links to Vila Henrique de Carvalho and Portugália are provided by road and by scheduled airline services. (A. A. G. P.)

MALAREN (LAKE MALAR), Sweden, extends 75 mi. W from Stockholm, which lies at its junction with the Saltsjön, an arm of the Baltic sea. The height of the lake normally reaches only one foot above sea level, and its outflow is sometimes reversed. The area is 440 sq.mi.; the deepest sounding is 210 ft. Mälaren contains numerous islands and its outline is very irregular; the mean breadth is about 15 mi. but an arm extends northward for 30 mi., nearly to the city of Uppsala. With Hjälmaren it drains an area of 8,160 sq.mi.

The lake is connected by navigable channels with Hjälmaren to the southwest and by the Södertälje canal and two channels at Stockholm with the Baltic to the south. The more important towns, besides Stockholm, are Västerås on the north, Södertälje and Eskilstuna near the south shore.

The lake provides a recreational area fully appreciated by the inhabitants of Stockholm, many of whom have residences on its shores. On the island of Drottningholm (Queen's Island, named in honour of Catherine, wife of John III) is a palace with a fine park and formal gardens, a summer residence of the royal family. It was built by Nicodemus Tessin and his son Nicodemus in the second half of the 17th century, on the site of a palace built by John III. Associated with the palace is the delightful Court theatre which was built in the 1760s and, along with that at Gripsholm castle, is the only 18th-century theatre maintained in a workable condition. Near Mariefred, on the south shore, is the picturesque castle of Gripsholm, begun in 1537 by Gustavus I Vasa, which contains a large collection of portraits. Strängnäs, also on the south shore, became an episcopal see in 1291, when the fine cathedral, later much altered, was consecrated. In the episcopal palace there is a 15th-century building later used as a school, Gustavus Vasa was elected to the throne of Sweden in 1523.

On the northward arm of the lake is the palace of Rosersberg later used as a gunnery school, in a well-wooded park. On a branch of the same arm is Sigtuna, a village whose ruined churches attest to its former rank among the principal towns of Sweden after its foundation in the 11th century. Remains prove that on Björkö, an island in the eastern part of the lake, there was a large settlement of earlier importance than Sigtuna. There, a cross commemorates the preaching of Christianity by St. Ansgar in 829.

On the northern arm of Mälaren, about 10 mi. S. of Uppsala, is the château of Skokloster, occupying the site of a nunnery. It was presented by Karl IX to Field Marshal Hermann von Wrangel, whose son Karl Gustav von Wrangel stored it with remarkable collections of trophies from Germany, taken during the Thirty Years' War, including a library, an armoury and a great collection of curios.

(A. C. O'D.)

MALARIA, an infection principally of man, apes, monkeys, birds and reptiles. It is caused by several species of Protozoa (one-cell animal organisms) which are classified as blood Sporozoa (suborder Haemosporididae) and belong to the single genus *Plasmodium* (see PROTOZOA: *Natural History*). As far as is known, all are transmitted by mosquitoes.

A given species has a limited ability to infect both vertebrate and mosquito hosts. Thus, *Plasmodium brasilianum* can be transmitted to several species of new world monkeys and marmosets but never has been successfully transmitted to old world monkeys. The culicine genera *Culex* and *Aedes* are the most important transmitters of bird malaria, whereas the genus *Anopheles* is the sole known transmitter of the human species. In a zoological sense, the mosquito in which the parasite undergoes its sexual processes is the definitive host, and man or other vertebrates are the intermediate hosts.

The stages of the malarial parasites that invade mature red blood cells containing hemoglobin in the vertebrate host have the interesting biochemical habit of splitting hemoglobin into its pigment, heme, and the protein carrier, globin. The parasite utilizes the globin and discards the heme. When the heme accumulates in the red cells and in various organs, it is known as malarial pigment. The same method of producing pigment occurs in infections caused by close relatives of the malarial parasites that belong to the genera *Haemoproteus*, infecting birds, and *Hepatocystis*, infecting monkeys, bats and squirrels. These infections are frequently, but inappropriately, referred to as malaria.

The present article will deal chiefly with the malarial parasites of man. In addition to the knowledge gained by the study of the naturally acquired disease, much information about malaria in man has been obtained by inducing malaria in volunteers and, as a treatment of the late stages of syphilis, in neurosyphilitic patients. The laboratory study of simian, rodent and avian species of malaria in various hosts also has contributed to the understanding of the disease.

Clinically, malaria is characterized by periodic paroxysms, popularly known as chills and fever, and a tendency to assume a chronic form with frequent relapses. During World War II there were marked advances made in the treatment of the disease and the discovery of efficient insecticides gave promise of removing the disease as one of the leading scourges of the inhabitable world, particularly in the tropic and subtropic areas.

History.—Malaria is one of the most ancient infections known to man, having been noted in some of the earliest records (5th century B.C.) when Hippocrates differentiated the fever into different types: namely, quotidian (daily), tertian (alternate days) and quartan (fever three days apart) types. He further observed that those who drank the stagnant marsh water had large stiff spleens, a characteristic of the disease, and fatal dropsy was common among them. It is not known when malaria first made its appearance in the Americas, but it is highly probable that it was a post-Columbian importation; some rather severe epidemics were first noted in 1493. The origin of the word malaria is not known, although reputedly it refers to *mal aria*, meaning "evil air." There has always been recognition of the association between swampy, marshy areas and the disease, although the exact roles of the mosquito and the parasite were not known until the beginning of the 20th century.

An effective treatment was known long before the cause of the disease was understood. Many legends indicate that the countess of Chinchón, suffering from chills and fever, was treated in the 1630s with an infusion of the bark of a certain tree in Peru. The reason why the infusion was used is not exactly clear, although certain Jesuits were thought to have learned about it from the natives. Discovery of the countess' diary failed to reveal that

she had ever had malaria. The fact remains, however, that the tree with the therapeutically active bark was named for her as the cinchona tree; and from 1700 its most active principle, quinine, was used universally for the treatment of malaria.

The first person known to have described the malarial parasite and to have recognized it as the cause of the disease was Alphonse Laveran (1880, Algeria). In 1886 the Italian investigator Camillo Golgi, known best for his studies on the structure of the nervous system, pointed out that the paroxysms are coincident with the segmentation of the blood parasites. Detailed knowledge of the tissue stages came later and represents the work of many investigators. The development of the early tissue stages was described first (1934-35) in the avian malarials and later (1948) in the simian and human malarials.

The discovery of the mosquito transmission of the disease was preceded by an exciting race toward the end of the 19th century. Two U.S. investigators, Theobald Smith and F. L. Kilborne, had shown between 1889 and 1893 that the tick is the carrier of the piroplasm producing Texas fever of cattle and thus laid the basis for the demonstration of the role not only of ticks but also of other arthropods, such as mites, crustacea and especially insects, in the transmission of human and animal diseases. Various people had speculated that malaria is transmitted by mosquitoes; they included Sir Patrick Manson, who in 1894 strongly supported this theory. In 1898 Sir Ronald Ross, a British physician in India, proved that bird malaria is transmitted by *Culex* mosquitoes and described the entire development of the parasite in the mosquito. Just the year before he had seen pigmented cysts in anopheline mosquitoes fed on patients with falciparum malaria. In Nov. 1898 the Italian investigators A. Bignami, G. B. Grassi and G. Bastianelli first infected man by mosquitoes, described the full development in man and noted that malaria is probably transmitted only by anopheline mosquitoes, an observation that continues to hold true. The disease can be transmitted unnaturally by common use of a hypodermic needle, as among drug addicts, or by blood transfusion from infected donors.

A major event in therapy was the mass cultivation by the Dutch in the East Indies of strains of cinchona trees giving high yields of quinine alkaloids. In 1891 P. Guttman and Paul Ehrlich found that methylene blue had a slight therapeutic effect. The shortage of quinine in Germany during World War I led to the research of W. Schulemann and his associates that culminated in the discovery of pamaquine (Plasmochin) in 1924. It was made by modifying methylene blue. In the early 1930s W. Kikuth, in collaboration with H. Mauss and F. Mietzsch, produced quinacrine (Atabrine, Atebrine or mepacrine). Both compounds are potent antimalarials. The discovery of improved synthetic compounds just before and during World War II by German, U.S. and British investigators presaged eventual replacement of both quinine and quinacrine.

Outstanding events in the history of malaria control included the vast projects conducted in Panama by William C. Gorgas, who practically eliminated the disease that, with yellow fever, had previously prevented the construction of the canal; the restoration of the Pontine marshes as a place of healthful habitation for the Italians; the species eradication of *Anopheles gambiae* from Brazil by the Brazilian government, initiated and directed by the Rockefeller foundation; and the elimination of malaria in many other areas of the world. The acute problem in Brazil resulted from the transmission by aircraft or surface craft of an effective vector from Africa; the vector spread over many thousands of acres and was responsible for an epidemic in which thousands of persons died. Although pyrethrum and kerosene sprays had been used to kill the larvae and adults of mosquitoes, their effectiveness was surpassed by DDT (dichloro-diphenyl-trichloroethane), first synthesized in 1874 by O. Zeidler and rediscovered in 1939 by P. H. Müller (*q.v.*), who was the first to recognize its insecticidal properties. DDT was tested successfully during World War II against many insects including malaria mosquitoes, and following the war was used in antimalaria campaigns throughout the world.

Distribution and Prevalence of Malaria.—Malaria is a world-wide disease, and there are probably more cases of it than

of any other major infection. It is most common in the tropics, where climatic conditions are favourable for the mosquito and for transmission of the disease throughout the year. As one approaches the poles it becomes less prevalent, although it has been recorded as far north as Archangel, U.S.S.R. In the United States malaria was once a severe menace in the south, the Mississippi river basin and lower California. By the early 1960s, however, it was at its lowest ebb in history; in 1961, for example, only 85 cases were reported in the U.S. and 77 of the cases were of foreign origin. Endemic areas are in Central and South America, north and central Africa, some countries bordering the Mediterranean and the near, middle and far east. Areas still malaria-free because of the absence of mosquito vectors include such Pacific areas as the Fiji Islands, Hawaii and Guam.

In 1955 it was estimated that malaria caused 250,000,000 cases of illness and 2,500,000 deaths annually in the world and that more than 1,100,000,000 people were exposed to the disease by living in malarious areas. By 1962 the World Health organization estimated that the number exposed to malaria risk had been reduced to 406,000,000.

Vivax malaria is the most widespread variety because of its ability to withstand therapy and remain chronic. Falciparum malaria, the most malignant, requires higher temperatures for optimal development; hence it is confined more closely to the tropical areas. In west Africa, for example, it exists almost to the exclusion of the other varieties. Malaria caused by *Plasmodium malariae* is very prevalent in some areas. Instances of this infection persisting without active relapse for 40 years or more have been recorded.

Many factors determine the distribution and incidence of malaria: in addition to those of cardinal necessity—the anopheline mosquito, a reservoir of infection and a susceptible human population—are included climate, rainfall, occupation, housing conditions, agriculture, wars, migrations of peoples, economic conditions, etc.

The Parasite.—Four species of the parasite are known to produce disease in man, *P. vivax*, *P. falciparum*, *P. malariae* and *P. ovale*. They cause, respectively, vivax (tertian), falciparum (subtertian or malignant tertian), malariae (quartan) and ovale tertian malaria. Each species has an asexual cycle in the tissues and blood of man and a sexual cycle that starts in the red blood cells of man and is completed in the mosquito.

The accompanying figure illustrates the life cycle of *P. vivax*. The infective stage (sporozoite), which is introduced into man by the bite of the mosquito, initiates a series of generations of pre-erythrocytic stages that occur in liver cells before parasites invade the red cells. These in turn develop into erythrocytic stages, so named because they infect red blood cells. (Except in *P. falciparum*, the pre-erythrocytic stages also give rise to exo-erythrocytic stages that not only can maintain themselves in cells but also can develop into erythrocytic stages. Since the persistent tissue stages are resistant to most drugs, they probably keep the infection going and relapsing. As far as is known, they do not produce clinical symptoms.)

During the erythrocytic asexual cycle, a young ring stage in *P. vivax* requires nearly two days to grow and develop into a segmenter containing 12 to 24 daughter parasites (merozoites). (Other species require different lengths of time for development and produce different numbers of merozoites.) The infected red cells then rupture and each daughter parasite that survives—many die—invades a new red cell. A remarkable aspect of the asexual cycle is that the parasites grow and divide synchronously and therefore at the time of segmentation the parasitized erythrocytes disintegrate in batches and liberate malarial pigment and other residues of parasite and red cell. This process, provided enough parasites are present, produces the typical, regularly recurring malarial paroxysm, which lasts four to ten hours and consists successively of a cold stage (chill), a hot stage and a sweating stage. The cold symptoms of the chill are subjective as they occur after the body temperature is elevated. Between paroxysms, the temperature may be normal or subnormal. The chart shows the relation of the asexual blood cycle and the

MODIFIED FROM W. H. TALIAFERRO, "MICROORGANISMS AND THEIR ROLES IN NATURE," "THE WORLD AND MAN," AND FROM C. G. HUFF, "A MANUAL OF MEDICAL PARASITOLOGY," BY COURTESY OF W. H. TALIAFERRO, C. G. HUFF AND THE UNIVERSITY OF CHICAGO PRESS

LIFE CYCLE OF PLASMODIUM VIVAX IN MAN AND THE FEMALE ANOPHELINE MOSQUITO. SHOWING THE FEVER CURVE IN MAN AS IT IS CORRELATED WITH THE ASEXYAL CYCLE OF THE PARASITE IN THE BLOOD AND WITH THE BEGINNING OF THE SEXUAL CYCLE IN THE BLOOD. (See TEXT.)

paroxysms of chills and fever resulting from a single brood of *P. vivax*.

A regular tertian fever because of the two-day cycle is produced by *P. vivax* and *P. ovale*. A quartan fever is produced by *P. malariae*. (The terms tertian for a two-day interval and quartan for a three-day interval arise from the classical method of including the first and last day of each interval.) The development of *P. falciparum* may be asynchronous at times so that the fever is more or less continuous with chills and sweating at irregular intervals. In this species, only the young rings (i.e., the small mononuclear parasites at the start of the asexual cycle) and sexually mature stages of gametocytes are usually seen in blood smears; the other stages develop in the deeper blood vessels of the body. Infections with one or more species can occur simultaneously. Furthermore, a double brood of tertian parasites can segment on alternate days, giving a daily, or quotidian, fever. Double or triple broods of the quartan parasite, *P. malariae*, may occur with chills and fever for two days followed by a free day or with fever every day.

After the blood stages have developed asexually about ten days, ring stages similar if not identical to the asexual ones initiate the sexual cycle. The young sexual parasites do not segment but grow into male forms (microgametocytes) or female forms (macrogametocytes), which eventually perish if not taken up by a susceptible female anopheline mosquito. In a susceptible mosquito they undergo maturation and fertilization similar to that of the

germ cells of higher animals. The process of forming microgametes (equivalent to spermatozoa in higher forms) is termed exflagellation because the filamentous microgametes behave very much like flagellums as they lash about in freeing themselves from the original gametocyte. After becoming free, a single microgamete fertilizes a macrogamete (equivalent to an ovum). The resulting ookinete (so-called because it actively moves) becomes an oöcyst on the outside stomach wall. Within a week or ten days, these oöcysts produce hundreds of sporozoites, which are the infective form and which migrate to many parts of the mosquito, especially the salivary gland. From this site they are injected by the bite of the mosquito into the vertebrate host, initiating a new infection.

Malarial parasites have been difficult to cultivate in the laboratory. Some progress, however, has been made with parasites of the asexual and sexual cycles. The parasites remain viable at extremely low temperatures, -65°C ., and this characteristic has been utilized to preserve various strains for research.

The Mosquito Vector.—Anopheline mosquitoes are the only known vectors of human malaria, and approximately 65 different species perform this function in different parts of the world. These mosquitoes undergo an aquatic larval stage, pupate and hatch into flying adults in about ten days, depending on the temperature of the water. The females require blood meals to produce fertile eggs; the males, which cannot bite, live on plant juices. According to the species, some prefer animal to human blood, hence are not good malaria vectors. Different species may live preferentially in streams, ponds, hoofprints, tree holes, in shade or sunlight. Usually their flight range is one mile or less from the source of human blood and infection. These mosquitoes are distributed throughout the world, more prevalently in the tropics, but some are present at latitude 50°N . They have been reported at an altitude of 9,000 ft.

The Disease in Man.—The disease in man is recognized by periodic chills and fever, anemia and, later, cachexia (general poor health) and an enlarged spleen. The different patterns of chills and fever have been described above. In falciparum malaria the symptoms are much more severe than in the other types. This type may be accompanied by various symptoms depending largely upon the localization of the asexual parasites. Intestinal localization may produce diarrhea and vomiting, and cerebral localization may cause delirium or coma. Only prompt treatment can prevent death in these severe infections.

Diagnosis.—Once clinically suspected, the disease is diagnosed by identification of the parasite in stained blood smears. A dehemoglobinized drop of blood can also be stained. The parasites take a characteristic stain, and all stages can be identified if present and properly stained. There are no satisfactory serological diagnostic tests such as precipitin or agglutination. The white blood cell (leucocyte) count is usually low and mild anemia is a constant finding. Usually an enlarged spleen can be palpated, especially in children.

Immunity.—A malaria infection confers a low-grade but specific immunity upon its host after the acute attack has subsided. This acquired immunity in man is of short duration, since an organism may produce repeated attacks in a person within a relatively short space of time. In experimental animals the residual immunity following complete eradication of the infection persists only a few weeks. There is no cross immunity in human malaria, as it is frequently observed that a person may have a simultaneous infection with two or more types of malaria. It is highly probable that a person develops resistance only to the malaria in his particular locality; for example, it has been shown that a person immune to a strain of vivax malaria in Florida reacts normally when exposed to infection from a vivax parasite from Cuba. Immunity is fundamentally antiparasitic, i.e., directed against the parasite, and is not antitoxic. Immunological suppression of the blood infection is brought about chiefly by macrophages (sometimes called scavenger cells) of the spleen and liver and, to a lesser extent, the bone marrow. These organs are the most important of the so-called filter organs of the blood and their macrophages, which are part of the reticuloendothelial system, are so oriented as to re-

move material from the blood. The macrophages phagocytize (eat) many parasites and parasitized red cells throughout the infection and especially after the development of active immunity, which is due, undoubtedly, to specific antibodies. Moreover, the macrophages themselves markedly increase in number chiefly by development from lymphocytes and monocytes. Immunity against pre-erythrocytic and exo-erythrocytic stages also occurs in some avian malarials and may occur in man. It has not been thoroughly studied.

Drug Treatment and Prophylaxis.—Antimalarial drugs may be used either curatively to treat malaria or prophylactically to prevent the disease. Suppressive treatment or clinical cure primarily involves the administration, during acute attacks, of drugs that will quickly suppress the population of blood asexual parasites so that symptoms disappear. In general, such treatment does not eliminate the exo-erythrocytic stages in the tissues. Regular suppressive treatment may be used in infected persons to prevent the asexual blood stages from reaching a level at which symptoms appear. However, an infection acquired during suppressive treatment may flare up after treatment is stopped unless an adequate immunity has been built up. It was the only type of drug prevention available when quinine was the sole antimalarial. Causal prophylaxis occurs only with drugs that prevent the infection by killing or inhibiting the development of sporozoites and pre-erythrocytic tissue stages. Radical cure is brought about by drugs that can eradicate all stages of the parasite, both in the blood and in the tissues. After such a cure, no relapse is possible, but a new infection can take place. It would seem at first glance that only those drugs should be used that give true causal prophylaxis and radical cure. The suppressive drugs, however, often act on the blood parasites much faster than do the curative drugs. Therefore, both kinds of drugs are often prescribed, particularly with vivax malaria, to relieve symptoms quickly and to eradicate the infection eventually. Under certain conditions, such as active military operations, suppression (clinical prophylaxis) may be superior to causal prophylaxis. Thus, suppression with drugs allows the development of a low-grade infection during which immunity develops and is maintained under conditions where it is very difficult to maintain an effective dosage level of a causal prophylactic drug.

Treatment of malaria depends upon the species of parasite involved. Untreated vivax, ovale and quartan infections eventually subside, but untreated falciparum malaria may be fatal. In fact, falciparum malaria is responsible for practically all uncomplicated deaths from malaria. It is, however, easier to cure than the so-called benign malarials, which is perhaps due to a difference in the tissue stages. Pre-erythrocytic stages of *P. falciparum* in the liver presumably are not long lived and give rise only to initial erythrocytic forms that usually are easily and radically cured by modern drugs. In contrast, *P. vivax*, *P. malariae* and *P. ovale* produce, in addition to blood stages, persistent tissue exo-erythrocytic stages that are responsible for long-term relapses. The tissue exo-erythrocytic stages can be eradicated only by a few of the newer drugs. In this connection, it is interesting that a vivax infection, when transmitted by a transfusion of blood from an infected person, can be cured by any effective suppressive drug including quinine because no tissue stages occur.

Older Drugs.—The importance of quinine cannot be overemphasized. Without it many of the most fertile areas of the world would never have become habitable. Its chief shortcoming has been its inability to eradicate relapsing infections such as vivax malaria. It may also give rise to partial deafness. Quinacrine is effective; its disadvantages are that it also does not cure vivax infections, it discolours the skin and, at times, leads to gastric disorders, skin rashes and, rarely, serious mental disorders. In 1928 the English investigators J. A. Sinton and W. Bird discovered in India that pamaquine (Plasmochin), an 8-aminoquinoline, would cure vivax malaria, as indicated by a greatly reduced relapse rate. The drug was too toxic for wide use but led directly to the development of other 8-aminoquinolines. The best of these, primaquine, was first found effective in man by Alf S. Alving and his associates.

Later Drugs.—Because of the shortage of quinine, an intensive research program was initiated during World War II by the National Research Council of the United States. As a result, United States and British investigators developed several drugs with superior therapeutic properties. In one group, called the 4-aminoquinolines, is the drug chloroquine, whose chemical name is 7-chloro-4-(4-diethylamino-1-methylbutylamino)-quinoline. It was first synthesized in 1934 by German scientists. It is superior to quinine or quinacrine because it is less toxic, relieves symptoms more quickly by eliminating the asexual blood stages more rapidly, can radically cure falciparum infection and prolongs subsequent latent periods. The ultimate total relapse rate for the vivax type of parasite, however, is the same for all three drugs.

Amodiaquin, like chloroquine also a 4-aminoquinoline, was discovered in 1946 by J. H. Burckhalter and his co-workers. It is similar to chloroquine in its nontoxicity and effectiveness. Other members of this group include hydroxychloroquine and ampyroquin.

Primaquine, or 8-(4-amino-1-methylbutylamino)-6-methoxyquinoline, is an 8-aminoquinoline that is much less toxic than pamaquine. Its outstanding characteristic is that it can radically cure vivax malaria. It is not, however, very active in eliminating the blood parasites. Hence, during an acute attack or during an appreciable parasitemia, it is combined with an effective suppressive drug such as quinine, chloroquine or amodiaquin. Quinacrine is not used for this purpose as it seems to increase the toxicity of primaquine. Pentaquine and isopentaquine, two other 8-aminoquinolines that were developed a few years earlier by U.S. workers, have not been widely used because they are more toxic than primaquine. Chloroguanide, a biguanide, was developed by the British. It has a very low toxicity, acts against the blood and tissue stages and is relatively cheap. However, its clinical action is relatively slow and, in addition, many strains of malaria have become resistant, thus limiting its usefulness.

A more recent drug, pyrimethamine, or 2,4-diamino-5-*p*-chlorophenyl-6-ethylpyrimidine, was first synthesized in the United States and tested there and in England. It is relatively nontoxic and has a marked prophylactic value. Not only is it a suppressive prophylactic to both vivax and falciparum malaria when given at weekly intervals but it also acts as a true causal prophylactic, when begun soon enough, by arresting the early pre-erythrocytic stages. It is also effective against *P. malariae*. Pyrimethamine only slowly suppresses acute attacks. It is, therefore, often supplemented by such drugs as chloroquine, amodiaquin, quinacrine or quinine.

It is interesting that some of the antimalarial drugs have been found to be effective in other infections. Thus, chloroquine and amodiaquin are used to treat the dysentery amoeba *Endamoeba histolytica* when it has invaded the liver; quinacrine has been found to be active against infections with some of the intestinal tapeworms and the intestinal protozoan *Giardia lamblia*.

Acquired drug resistance is an important factor in antibiotic therapy. It does not occur to any appreciable extent with quinine and was first noted in the case of chloroguanide. Resistance against chloroguanide and pyrimethamine has developed in several species. *P. falciparum* resistance against the 4-aminoquinolines (chloroquine, amodiaquin, etc.) was reported in the 1960s in South America and Asia. Because of the widespread use of these drugs, such resistance is important.

Control.—The methods of control of malaria are varied according to the habits of the particular mosquito involved. Elimination of all breeding places of *Anopheles* by drainage or filling is essential wherever practical. Human beings should be protected from the bites of mosquitoes. Dwellings should be screened and bed nets used, since most *Anopheles* feed at night. The use of residual sprays of the chlorinated hydrocarbon series of insecticides (DDT, lindane, dieldrin) is the most important method of controlling mosquitoes. The mosquitoes that rest on the walls or surfaces covered by the insecticide absorb a lethal dose of the chemical. When applied on water surfaces, DDT and dieldrin can kill the mosquito larvae. Mosquito control has become complicated, however, by the development of resistance to insecticides.

At least 18 vectors had become resistant by the 1960s to either DDT or dieldrin. When resistance occurs to one, the other may be used but seven species of mosquitoes were known to be resistant to both types. Organophosphorus compounds, such as malathion also were used. However, they are highly toxic and great care in handling is necessary. A gaseous insecticide (DDVP, or dimethyl-dichloro-vinyl-phosphate), also a phosphorus compound was tested in the early 1960s for possible use.

There are other natural methods, such as the introduction of the surface-feeding minnow *Gambusia*, a natural enemy of the mosquito; increasing the salinity of water near the seaside by tide gates; raising and lowering water levels; and eliminating protruding vegetation and debris from the breeding places, thus making it unfavourable to the mosquito. In some areas it is possible to reduce the reservoir of infection, thus interfering with transmission, by the use of drugs, particularly the later ones. These are but a few of the many applicable methods.

Blackwater Fever.—Blackwater fever is the most serious and the least understood complication of malaria. It is characterized by a rapidly developing and severe anemia, passage of dark-red to black urine, signs of severe toxicity and a high mortality. It is usually a complication of malaria of the falciparum variety although occasionally it may appear after an attack of vivax or quartan malaria. The incidence of blackwater fever seems to be in proportion to the amount of malaria in a certain area. Non-immune immigrants in heavily endemic areas are frequent sufferers from this complication. In west Africa, where blackwater fever is prevalent, it was found to occur once in every 900 attacks of malaria. It seldom appeared in a person until he had had at least four attacks of malaria and had been in the area for six months. The disease does not appear to be caused simply by repeated attacks of vivax malaria because it was not observed by L. T. Coggeshall in more than 5,000 relapsing cases with an average of 14 relapses per patient. It is theorized that after repeated attacks of malaria, usually with *P. falciparum*, a factor is formed that lyses the red blood cells. Other predisposing factors may be quinine, a previous attack of hemoglobinuria and intense malaria infections.

Symptomatology.—The onset is usually accompanied by single or multiple rigors and extreme prostration. There is no characteristic pattern of fever, although it is usually high, 103° to 105° F. (39° to 41° C.). The pulse is rapid, and the patient usually exhibits a considerable degree of pallor. With the hemolytic crisis there is a profound drop in the number of red cells, so that the count may be as low as 2,000,000. Jaundice makes an appearance early in the course of the disease. Vomiting and anemia are frequently observed.

Prognosis and Treatment.—The general mortality rate is 25–50%. If the patients are anuric (lacking in the excretion of urine) the rate may be higher. Repeated hemolytic crises tend to affect the prognosis adversely. One attack of blackwater fever predisposes to others; the patient should therefore be removed from the endemic malarious area upon recovery. Treatment is entirely supportive; if parasites are present, antimalarial drugs other than quinine or the 8-aminoquinolines should be given.

Simian Malaria.—There are about 19 species of simian malarials, several of which were first described in the 1950s and 1960s. Some of these, such as *P. rodhaini* of chimpanzees and *P. knowlesi* of monkeys, have been transmitted to man by the inoculation of infected blood. When induced malaria was the principal method of treating neurosyphilis, *P. knowlesi* was used in some cases because it ran a short mild course of fevers.

It has been demonstrated that a vivax type of monkey malaria, *P. cynomolgi*, can be transmitted 'experimentally' to man, from man to man, and from man to monkeys by infected mosquitoes. It was believed possible that additional simian species also can be transmitted experimentally to man.

A few instances of the transmission of human malaria to monkeys, such as the transmission of *P. falciparum* to the howler monkey, have been reported. The communicability of the malarial parasites between man and other animals had, at the mid-1960s, been shown only under experimental conditions. There was no

proof that zoonotic malaria is of any importance in the prevalence of human malaria in nature.

MALASPINA, an Italian feudal family, with extensive possessions mainly in the western Apennines and the Lunigiana. It appears to descend from the margrave Otbert II, who opposed the emperor Henry II in the 11th century. The situation of their lands, largely in mountainous regions and scattered over a wide area, helped the Malaspina to resist, in the 12th century, territorial expansion by Piacenza and Genoa. Like other feudal houses of medieval Italy, they were, however, weakened by repeated partitions; in 1221 their possessions in the Lunigiana as well as in the Val Padana and in Sardinia were divided between the line of the *Spino Secco* and that of the *Spino Fiorito*; then in 1266 the lands of the *Spino Secco* line were divided among the branches of Mulazzo, of Val di Trebbia, of Villafranca and of Giovagnolo; and in 1275 the lands of the *Spino Fiorito* line were divided among the branches of Filattiera, of Olivola and of Verrucola and Fivizzano. Despite this fragmentation of their territories, the Malaspina remained, during the 14th century, one of the leading feudal houses of Tuscany. SPINETTA MALASPINA (d. 1352) of Verrucola even extended his dominions in the Lunigiana and the Garfagnana. But the partitions finally undermined the resistance of the Malaspina to municipal pressure: in the 15th and 16th centuries, most of their dominions came under Genoese or Florentine control. The descendants of Spinetta's great-nephew Spinetta (d. 1398) were more fortunate: the latter's son ANTONIO ALBERIGO acquired Massa and Carrara (1421, 1428); and the marriage of RICCIARDA MALASPINA (Antonio Alberigo's great-granddaughter) to Lorenzo Cybo (1515), enhanced the importance of this branch's dominions, which under Cybo Malaspina became in 1568 the principate and in 1633 the duchy of Massa.

MALATESTA, an Italian family which ruled Rimini (q.v.) and a number of adjacent cities in Romagna and Le Marche during the later middle ages. Like their hostile neighbours, the Montefeltro (q.v.), the Malatesta first appear as feudal lords and landowners of the Apennine hinterland of Rimini, who in 1197 and again in 1216 were forced into formal submission to the commune. Since they kept their seigniorial rights and property—property to which they steadily added during the 13th century, especially by marriage and emphyteutic grants from churches—they simply carried their influence with them into the town, where by the second half of the century they had captured the leadership of the local Guelphs, not only in Rimini but in Romagna generally. At that time the head of the Riminese branch of the family (there was another, Ghibelline, branch at Sogliano) was MALATESTA DA VERRUCCHIO (d. 1312), and it was he who, after the usual vicissitudes of urban faction, compromise and exile, finally expelled the Ghibelline leaders, the Parcitadi, in 1295 and became effective lord of the city. The best-known episode of Malatesta history also occurred during this period, in 1283 or 1284, when GIANCIOTTO (d. 1304), son of Malatesta, murdered his wife, Francesca da Polenta, and his brother, PAOLO, for adultery (Dante, *Inferno*, v, 73 ff.).

Forty years elapsed before the lordship of the Malatesta in Rimini was given constitutional form. During that time, under

Malatesta da Verrucchio's sons MALATESTINO (d. 1317) and PANDOLFO (d. 1326) and Malatestino's son FERRANTINO (d. 1353), they gradually extended control to the nearby towns of Cesena, Fano, Pesaro and Senigallia; but they also fell out among themselves, which was one reason why for a short time (1331-33), while Bertrand du Pouget was papal legate, they altogether lost possession of Rimini. They recaptured the city in 1333; and in 1334 Pandolfo's sons MALATESTA II (d. 1364) and GALEOTTO (d. 1385), after driving Ferrantino out, were finally created lords of Rimini by "popular" suffrage. Once again the Malatesta proceeded to establish a large territorial state, based on Rimini; and by the arrival of Cardinal Albornoz (q.v.) in 1353 they had occupied most of the march of Ancona as far as Ascoli. Albornoz compelled them to surrender many of their conquests but allowed them to remain, as papal vicars, in Rimini, Fano, Pesaro and Fossombrone (1355). The vicariate was later renewed, and Malatesta II was succeeded by his sons MALATESTA UNGARO (d. 1372) and PANDOLFO (d. 1373) and by his brother GALEOTTO. Pandolfo Malatesta ruled over Pesaro and started the independent line of the Malatesta of Pesaro, which came to an end in 1445 when his grandson GALEAZZO MALATESTA (probably d. 1457), oppressed by debt and harassed by his neighbour Sigismondo Pandolfo Malatesta, sold Pesaro and Fossombrone to Francesco Sforza and Federigo da Montefeltro. Rimini and the other towns passed on Galeotto's death to his sons CARLO (d. 1429), PANDOLFO (d. 1427), ANDREA (d. 1416) and GALEOTTO BELFIORE (d. 1400), who divided the state among them.

For many years after 1355 the Malatesta of Rimini remained faithful to their peace with the church and were rewarded by the powerless popes of the schism with comprehensive vicariates and grants of land and lordship. They were also active in the wars accompanying the formation, dissolution and reformation of the Milanese dominion in upper Italy under Giangaleazzo Visconti and his sons. Carlo was for a time governor of the Milanese state after Giangaleazzo's death, while Pandolfo possessed himself of Brescia (1404) and Bergamo (1408), which he had to relinquish in 1421. Carlo also achieved a momentary prominence in European politics by his association with Pope Gregory XII and his activity on behalf of Christian unity at the councils of Pisa and Constance. At Constance in 1416 he presented Gregory's formal renunciation of the papacy.

The end of the schism, however, and the election of a single pope, Martin V, in 1417, portended a revival of papal authority. The Malatesta were among the first to feel the change. Though Martin V consented to legitimate Carlo Malatesta's only heirs, namely Pandolfo's three bastards GALEOTTO ROBERTO (d. 1432), DOMENICO (called Malatesta Novello; d. 1465) and SIGISMONDO PANDOLFO (1417-1468), he also favoured their enemies, the Montefeltro and the Malatesta of Pesaro, and on Carlo's death deprived them of much of their territory (1430). Malatesta Novello, who governed Cervia and Cesena, was more dedicated to letters than to arms (he built the beautiful library at Cesena). For Sigismondo, however, the events of 1430 represented a compelling challenge to reprisal against his neighbours, and when Galeazzo Malatesta sold Pesaro to them in 1445, his sense of injury became obsessive.

Sigismondo has been regarded as embodying the type of Italian "Renaissance" prince. A generous and cultivated patron of writers and artists, he built the most splendid monument of Rimini, the elaborately symbolic Malatesta "temple," the church of S. Francesco. With the exercise of patronage he combined popularity as a ruler, distinction as a mercenary captain and a reputation for impiety, vice and brutality. This reputation he owed chiefly to systematic defamation by Pope Pius II. The most certain feature of his character was impetuosity, which made him impatient of keeping faith with princes often more powerful than himself. This was why, after years of feud with his detested rival Federigo da Montefeltro, he stood virtually alone when Pius II launched a crusade against him in 1461. By the peace of 1463 Sigismondo lost most of his dominions, and he and his brother were allowed to keep Cesena and Rimini only until their death.

All attempts to undo this decision failed. But after Sigis-

mondo's death, thanks to the favour of other Italian powers, his son ROBERTO "il Magnifico" (d. 1482) managed to recover Rimini (1469) and bequeath it to his own son, PANDOLFO (d. 1534). The price of this restoration, however, was increasing dependence on other states, especially Venice. At the same time, under Pandolfo Malatesta particularly, the family lost all popular support. So, when Cesare Borgia advanced against Rimini in Oct. 1500, the Malatesta had to flee. They tried three times to return (1503, 1522, 1527-28), but found no welcome or success.

Fasoli, "Gli studi storici sulle signorie romagnole," *Atti della Deputazione di storia patria per l'Emilia e la Romagna* (1938-39); P. J. Jones, "The Vicariate of the Malatesta of Rimini," *English Historical Review* (1952), and "The End of Malatesta Rule in Rimini," *Italian Renaissance Studies*, ed. by E. F. Jacob (1960). (P. J. J.)

MALATYA, the administrative centre of an *il* (province) of the same name in east-central Turkey, lies in an upland plain watered by a tributary of the Euphrates, the Tohmaşuyu, and surrounded by high mountains (Nuruhak Dagı 10,138 ft., Buz Dagı, Saksak Dagı and Kartal Tepesi). Pop. (1965) 105,207. The town is 148 mi. S.E. of Sivas by road and stands at the road and rail junction where the line from Fevzipasa (the junction for Aleppo, Syria) and the Taurus meets lines east from Elazığ and Diyarbakır and north from Sivas and Erzincan. Malatya is largely modern and an important industrial and agricultural centre. There are manufactures of cement, sugar and textiles.

The site of the modern town was first occupied in 1838 during the war with Mohammed (Mehemet) Ali of Egypt. The remains of the Roman and medieval city Melitene, now called Eski ("old") Malatya, are about 6 mi. N.E. Within the fortifications are a fine Seljuk mosque (Ulu Cami) and a large *han* (caravansary), both 13th century A.D. About four miles farther north a mound known as Arslan Tepe represents the remains of an even older city, named Milid in the Hittite records of the 13th century B.C. It was excavated from 1932 onward by French archaeologists, who found a palace of the 8th century B.C. with sculptured reliefs and a colossal statue of a king.

Soundings at Arslan Tepe have identified the remains of an early settlement of the 4th millennium B.C. In the later centuries of the 2nd millennium Milid became one of the more important cities of the Hittite empire and, after the destruction of the latter by the Phrygians in the 12th century B.C., survived as an independent city-state, sometimes linked with the "Neo-Hittite" federation (Sakjegözü, Ya'diya-Sam'al [Zenjioli or Zincirli], Carchemish, etc.) and sometimes subject to Assyria. Removed to a new site in Roman times, it acquired the status of a city again under Trajan and became the capital of Armenia Minor. Later it was successively occupied by Sassanian Persians and Arabs, and after its recovery by Nicephorus II, it became an important centre of the Jacobite sect, whose great historian, Bar-Hebraeus, was born there. In the 12th century it fell to the Seljuk sultanate of Rum.

MALATYA IL is divided administratively into eight *ilceler* or *kazalar* (districts). Area 4,718 sq.mi.; pop. (1965) 452,478, of whom about 150,000 were urban. Its fertile plain yields fruit, vegetables, cotton, sugar beet, tobacco, rice and grapes and there are available deposits of chrome, lead and copper.

See L. Delaporte, *Malatya: Arslantepe* (1940). (S. H. LL.)

MALAWI, formerly Nyasaland, a country in east central Africa and a member of the Commonwealth of Nations, is bounded north and northeast by Tanganyika (Tanzania), east, south, and southwest by Portuguese East Africa (Mozambique), and west by Zambia. Its area of 45,747 sq.mi. (118,485 sq.km.) includes 9,266 sq.mi. (23,999 sq.km.) of water, mostly Lake Nyasa (q.v.; called Lake Malawi locally from 1965). The capital is Zomba (q.v.).

PHYSICAL GEOGRAPHY

Geology, Structure, and Relief.—The greater part of Malawi is composed of Precambrian rocks comprising mainly gneisses, migmatites, pyroxene-granulites, quartzites, phyllites, and mica schists, with some crystalline limestones. Minerals associated with these include graphite, garnet, asbestos, iron ore, and ilmenite. Intrusions both of syenite and granite have pene-

trated these Precambrian rocks. Strata of the Karroo System occur both in northern and in southern Malawi where, in the Shire Valley, basaltic lavas are found. Later formations include small stretches of Lower Cretaceous strata in the northern part of the Rift Valley (where fossils of reptiles have been discovered) and in the Shire Valley. A period of igneous activity, which probably began in the Cretaceous, produced alkaline rocks occurring in ring-structures or as dikes associated with these.

The surface features of Malawi have been profoundly affected by large-scale faulting. The dominant feature of the surface is the north-south trending Rift Valley, formed by renewed rifting in the early Cretaceous along lines of crustal weakness. This rifting movement broke up what was probably an even plateau surface, and the country on either side of the rift is made up of plateaus at various elevations. The Rift Valley may be divided into two parts: the lake basin and the Shire River Valley to the south of it. The northern part of the lake basin is strongly faulted, the fault scarp of the Livingstone Mountains plunging 1,656 ft. (505 m.) below the lake surface (about 1,550 ft. above sea level), and the Ruwara Scarp on the western side submerging to 1,656 ft. below lake level off Usisya Bay. This faulting continues on either side of the Shire Valley almost to the confluence of the river with the Zambezi, the main scarp on the western side being the Mwanza "step" and that on the eastern side the Chileka "step." To the east of the Shire Valley, at the Mozambique border, rises the great syenite mass of the Mlanje Peak, which attains an altitude of 9,848 ft. (3,002 m.), the highest point in Malawi. The broad Muchinga watershed links the Zambian highlands with the Malawi highlands to the west of Lake Nyasa: Nyika Plateau, 6,500-8,550 ft. (1,980-2,606 m.); Nganda Hill, 8,550 ft.; and the Vipya Mountains, 5,000-6,400 ft. (1,500-1,950 m.). Three distinct physiographic regions may be recognized in Malawi: the highlands (land over 4,000 ft. [1,200 m.] in altitude); land between 2,000 ft. and 4,000 ft. in the western part of the country; and the Nyasa-Shire trough (Rift Valley).

Climate.—There are two main seasons: the dry season from May to October and the wet season from November to April. Altitude has an important effect upon temperature as is clearly seen in a comparison of the temperature of Nsanje (Port Herald) in the Shire River plain, which has a July mean of 21° C (69° F) and an October mean of 29° C (84° F), and Dedza at 5,355 ft. (1,632 m.) in the highlands of the Central Region, which has a July mean of 14° C (57.2° F) and an October mean of 20.5° C (68.9° F). On the Nyika Plateau in the Northern Region, at altitudes of about 8,000 ft. (2,400 m.) frosts are not uncommon in July. Annual rainfall is highest over parts of the northern highlands and on the Mlanje Peak, where it is about 90 in. (2,286 mm.), and lowest in the lower Shire Valley where it ranges from 25 to 35 in. (635 to 889 mm.).

Vegetation.—Along the Shire Valley and on parts of the shore of Lake Nyasa the characteristic vegetation is the baobab, the knobthorn (*Acacia nigrescens*), other species of acacias, a doum palm, and also, to a limited extent, mopane woodland. On the higher plateau areas vegetation is dominated by savanna or open woodland, the species most frequently found being the *Brachystegia* and *Julbernardia*. True forest is found in areas of high rainfall: the Mlanje Mountains and parts of the highlands in the north of the country. In these places grow the yellowwoods, the cedar, and species of *Cussonia*, *aphloia*, *croton*, etc. At lower levels the red and brown Rhodesian mahoganies (*Khaya nyasiensis* and *Lovoa swynnertonii*) are common. Pure grassland occurs on the Vipya and Nyika highlands above about 6,000 ft. (1,800 m.). Swamp vegetation occurs in the Shirwa-Chiuta depression and in the lower Shire Valley.

Animal Life.—Because of the pressure of population there are no large areas in Malawi where game abounds, although there is a fair selection of various species in the reserves. Elephants are found in Mijete, Kasungu, and Kota Kota areas. Among the primates are the vervet, Samango monkey, and larger bush baby. Carnivores include the lion, cheetah, leopard, serval, civet cat, genet, mongoose, black-backed and side-striped jackal, honey badger, and skunklike zoril. The great anteater and ground

BY COURTESY OF FEDERAL INFORMATION DEPARTMENT

MLANJE MASSIF, SOUTHEAST MALAWI

pangolin are other mammals of interest. The hippopotamus can be seen along the shores of Lake Nyasa, and the eland (including Livingstone's eland) occurs in large herds. Other Bovidae are the bushbuck, klipspringer, common waterbuck, reedbuck, inyala, oribi, hartebeest, and duiker. Other notable mammals are the zebra, Livingstone's suni, clawless otter, and white-necked otter. Reptiles are numerous and fish (bass, catfish, perch, carp, etc.) abound in the lakes and rivers. More than 600 species of birds have been recorded and there is a wide variety of insect life.

National Parks and Reserves.—There are five game reserves in Malawi: Kasungu (800 sq.mi. [2,072 sq.km.]) and Kota Kota (680 sq.mi. [1,761 sq.km.]) in the Central Region; Mwabvi (60 sq.mi. [155 sq.km.]) in the Nsanje District; and Mijete (70 sq.mi. [181 sq.km.]) and Lengwe (45 sq.mi. [117 sq.km.]) in the Chikwawa District. The country also possesses two "controlled areas," in which hunting was restricted: the Nyika grasslands (325 sq.mi. [842 sq.km.]) in the Rumpi District; and the Vipya controlled area in Nkata Bay District.

(J. H. WN.; X.)

HISTORY SINCE INDEPENDENCE

Malawi achieved independence as a member of the Commonwealth of Nations on July 6, 1964. Soon after a serious dispute arose between the prime minister, Hastings Banda, and other ministers. In September 1964 three ministers were dismissed and three others resigned in sympathy. Subsequently clashes occurred between supporters of the former ministers and members of the Malawi Young Pioneers and others who were loyal to Banda. Henry Chipembere, one of the dismissed ministers, escaped from house arrest and defied attempts to recapture him. By the early months of 1965 order was being maintained with the aid of strict security regulations enforced by European-officered troops and police. (For previous history see NYASALAND.)

POPULATION

In 1965 the estimated total population of Malawi was 4,000,000, the vast majority being Africans. At the 1956 census the African population was estimated at 2,570,000, and at the 1945 census it was 2,044,707. Between 1931 and 1945 it increased by more than one-third and between 1945 and 1965 by nearly 100%. Part of this increase was, however, the result of immigration into southern Malawi from Mozambique. At the September 1961 census of non-Africans there were 8,750 Europeans, 10,630 Asians, and 1,490 other non-Africans. The European population, which had been 1,975 in 1931, increased rapidly after 1945, when it stood at 1,948, reaching 6,732 in 1956, mainly as a result of immigration from the United Kingdom. The Asian and other non-African peoples (3,259 in 1945) maintained a consistently high birthrate, and had increased to 9,703 by 1956. The estimated population of the chief towns (European population, 1961 census, in parentheses) is: Zomba 7,200 (1,200); Blantyre-Limbe 59,700 (4,090) (*qq.v.*); and Lilongwe 8,100 (870). Most of the population of Malawi is

concentrated in the southern part of the country.

The African people of Malawi are of Bantu origin and the vast majority belong to the eastern section of the Bantu peoples. This is subdivided into a number of tribal groups, of which the most important are the Chewa (Chipeta), Lomwe, Nyanja, Yao, and Tumbuka. There is a considerable amount of intermixture among the various tribes. They are agricultural peoples, who cultivate maize (corn) and sorghum, who follow matrilineal descent, and practise uxori-local marriage. The Ngoni (*q.v.*), however, who established kingdoms by conquest in Malawi and are mixed tribally, cannot easily be fitted into this classification. Tribes were generally organized into small units led by chiefs with limited secular and spiritual powers. But from the beginning of the 20th century the African people have been increasingly subjected to the influence of western European civilization, many have been converted to Christianity, and some tribal customs have tended to fall into disuse.

The official languages are English, Nyanja, and Tumbuka. Nyanja is the lingua franca in the Central and Southern regions; Tumbuka is widely spoken in the Northern Region.

(J. C. ML.; X.)

ADMINISTRATION AND SOCIAL CONDITIONS

From the time of independence until July 6, 1966, Malawi was a constitutional monarchy acknowledging the British sovereign as chief of state. The governor-general, as the sovereign's representative, appointed as prime minister the member of the National Assembly who appeared most likely to obtain the support of the majority of the members of the Assembly. The cabinet was composed of the prime minister and other ministers appointed by him. In July 1966 a new constitution came into effect, establishing a republican form of government with a president as both chief of state and head of government. There is no vice-president or prime minister, and the president appoints his own cabinet. The National Assembly consists of 50 elected African members and a limited number of European members appointed by the president. Both the president and members of the Assembly are elected simultaneously every five years. Malawi retains its membership in the Commonwealth of Nations.

For local government purposes Malawi is divided into three regions, Northern, Central, and Southern, which are in turn divided into 20 districts. Each district has an elected district council, which controls its finances and is empowered to levy rates. Five of the larger towns have town councils, with councilors appointed by the governor. Blantyre-Limbe, however, has an elected municipal council.

Living Conditions.—In the early 1960s about 130,000 African people of all races were in paid employment in Malawi, the largest number in agriculture. Many Malawians continued to work outside their own country in the more industrialized countries such as Zambia, Rhodesia, and the Republic of South Africa which could attract labour with high wages. There are about 20

employees' trade unions in Malawi and the employment of labour is governed by an ordinance. There are also ordinances dealing with workmen's compensation, rates of wages, and conditions of employment.

Beside encouraging improvements in traditional housing the gov-

ernment pays close attention to housing problems in urban areas; in the most important townships land has been made available for high-density planning. There are government-financed housing schemes in certain towns and an urban housing loan scheme.

Health and Welfare.—In the early 1960s apart from a central hospital and two general hospitals, there were a number of district, rural, and special hospitals, including a mental and a leprosy hospital (leprosy is quite widespread). The main diseases are malaria, schistosomiasis, hookworm, and relapsing fever. The Department of Community Development and Social Welfare is concerned with village self-help schemes, adult literacy, training in homecrafts, youth work, recreation, the problems raised by urbanization, and the rehabilitation of the handicapped.

Justice.—The judiciary consists of the Supreme Court of Appeal, the High Court (comprising the chief justice and three puisne judges), magistrates' courts, and local courts. Appeals lie from the subordinate courts to the higher courts, and in certain cases to the Judicial Committee of the Privy Council. The Malawi police force, totaling nearly 3,000, is divided into three territorial police divisions, which are in turn subdivided into districts.

Education.—In the early 1960s there were more than 360,000 pupils in primary schools, a considerable number of which were run by missions, many being government-assisted. Primary schools are administered by local authorities. There were also nearly 3,000 pupils in secondary schools. There were nine teacher-training institutes for primary schoolteachers and Soche Hill College trained secondary schoolteachers. Technical education was provided by two government technical schools and a college of commerce offered a wide variety of subjects. A polytechnic which would provide a more advanced and specialized range of subjects, was being built. More than 400 students were attending higher education courses outside Malawi.

THE ECONOMY

The economy of Malawi is based on agriculture, in which the majority of the population is engaged. More than sufficient food is produced for the country's needs, leaving a surplus for export. Natural conditions, however, make much of Malawi unsuitable for cultivation. It has also proved impossible to exploit the country's known mineral wealth because of its inaccessibility. Manufacturing industries developed after World War II and now make an appreciable contribution.

Production.—Agriculture and Fisheries.—In the early 1960s the most important agricultural crops were tea and tobacco. Tea, grown on plantations owned by Europeans, employs the biggest proportion of labour. In the early 1960s with more than 30,000 ac. planted, annual production averaged nearly 30,000,000 lb. About 35,000,000 lb. of tobacco were marketed annually from plantations covering just under 130,000 ac. An increasing amount of Turkish tobacco is grown. Peanuts (groundnuts) are also an important cash crop. Among grain crops are maize (corn), sorghum, millet, rice, and wheat, grown mainly for local consumption, although some maize and rice are exported. Other export crops include cotton and tung oil. Some coffee is grown, chiefly by Africans in the Northern Region. The marketing of the chief African cash crops is handled by the Farmers' Marketing Board which aims at enabling the African producer to obtain a steady price and to improve the quality of his crops. By the early 1960s there were more than 120 cooperative societies, which purchased and marketed produce.

In the early 1960s there were about 380,000 cattle, 500,000 goats, nearly 80,000 sheep, and 100,000 pigs. Good progress in controlling various diseases has led to a considerable increase in the cattle population, notably among Africans in the Southern Region.

There is a fishing industry along Lake Nyasa; and other fisheries at Shirwa (Chirua) and Malombe lakes. The government encourages fishing by loans and other means, and is attempting to establish it on a regular commercial basis. Production is between 12,000 and 14,000 tons annually.

Forestry.—Of Malawi's 9,000 sq.mi. (23,300 sq.km.) of indigenous forest, about 3,700 sq.mi. (9,600 sq.km.) are set aside

PRINCIPAL COMMUNITIES AND PHYSICAL FEATURES OF MALAWI

BY COURTESY OF THE FEDERAL INFORMATION DEPARTMENT, SOUTHERN RHODESIA; PHOTO BY R. L. KIRBY

TEA ESTATE IN MALAWI

as state forest reserves. About 26,000 ac. (10,500 ha.) are plantations, mainly of softwood. Annual production of timber usually exceeds 2,300,000 cu.ft.

Mining, Industry, and Power.—Although exploration has revealed a considerable variety of minerals in Malawi, only a few (notably bauxite) are known to exist in quantities sufficient to be worth exploitation, and the geographical location of these has so far made it impossible to work them on a commercial scale. There has been notable progress in light industry and there are factories for assembling motor vehicles, and for the manufacture of cigarettes, soap, clothing, bricks, cement, furniture, fishing nets, and edible oils and fats. The Malawi Electricity Supply Commission is responsible for the generation and distribution of power, and covers the industrial areas of the Southern Region.

Trade and Finance.—The most important exports are tobacco, tea, peanuts, cotton, and other agricultural products. Only a few manufactured articles are exported. Among the chief imports are metals and metal manufactures, machinery and vehicles, textiles, clothing, and foodstuffs.

Currency issued by the Bank of Rhodesia and Nyasaland remains legal tender in Malawi until the establishment of the Reserve Bank of Malawi. Besides regulating the issue of currency the bank is empowered to control banking, to deal in gold and foreign currencies, and exercise exchange control functions. There are also two commercial banks: the Standard Bank, with branches at Blantyre-Limbe, Zomba, and Lilongwe; and Barclays Bank, Dominion, Colonial and Overseas (DCO), with branches at Blantyre-Limbe and Lilongwe.

Current expenditure by the Malawi government is financed from revenue: capital expenditure is charged to a special development fund instituted in 1957. In the mid-1960s revenue on the current account totaled about £9,000,000 annually and on the development account about £3,000,000. The main sources of revenue were income tax, customs and excise duties, and grants and loans from the United Kingdom. Expenditure on the current account was about £8,000,000 and on the development account £3,000,000. The main items of expenditure were education, public works, maintenance of law and order, and social services. The budget deficit was balanced by the British government.

Transport and Communications.—The railway runs from Salima near Lake Nyasa through Blantyre-Limbe down to Beira in Mozambique, where it links up with the line from Rhodesia. In the early 1960s there were about 280 mi. (450 km.) of permanent way in Malawi and almost 1,000,000 tons of freight were carried annually. The total road length was about 6,000 mi.

(9,650 km.), of which nearly 250 mi. (400 km.) were bituminous, and there were about 17,000 motor vehicles in the country. Roads link Malawi with Zambia and Mozambique, and through both these countries with Rhodesia. Malawi Railways also operates a steamship service on Lake Nyasa; vessels call at various ports in Malawi and also cross to Tanganyika. There are airports at Blantyre-Limbe and Lilongwe, and airfields at a number of other towns. Air Malawi operates internal services and there are also flights to Salisbury and Lusaka. Malawi has a broadcasting studio at Blantyre-Limbe and a station at Zomba. Programs are broadcast in English and in the vernacular languages.

MALAY, a people of southeast Asia and adjacent islands. It is thought that the neolithic ancestors of the Malays (proto-Austronesians, proto-Malays, Mongoloid Indonesians or Malaysians) descended from Yünnan province, southern China, between 2500 B.C. and 1500 B.C., down the valley of the Mekong river to the Malay peninsula, thence to Indonesia and on to Madagascar and Easter Island. They had already cultivated banana, sugar cane, millet and rice, domesticated pigs and buffaloes, and could count up to a thousand. They were boatbuilders and fishermen as well as hunters and agriculturists. These early peoples built houses of bamboo or wood on piles, made pottery in great variety, erected megaliths to dead chiefs and practised head-hunting. At about the beginning of the Christian era immigrants from India came to spread their cultural influence along with Buddhism, Sivaism and Vishnuism, until, between the 13th and 15th centuries, Islam ousted all religions except in Bali, which remained Hindu, and the Philippines, where the Spaniards introduced Roman Catholicism. The modern or deuterio-Malays are the primitive Malay with strains derived from intermarriage with the Chinese, Indians, Siamese and Arabs. The Malay groups bore many local names until, probably in the 13th century, they got their generic name from Jambi (*q.v.*; also called Melayu) in Sumatra.

Religion and Folklore.—Relics of animism survive in the Malay fear of malignant spirits of the soil and jungle, in dread of banshees hostile to pregnant women and in respect for holy places, rocks, trees, persons and animals. Except in remote hamlets, these beliefs now count for no more than a European's dislike of walking under a ladder. A thousand years of Hindu influence left ceremonials for weddings and the installation of rulers, many Sanskrit terms (even the word *raja* denoting an Indian rank) and a host of gods and demons for the invocations of the obsolescent shaman (*see SHAMANISM: Southeast Asia and Oceania*).

In 1292 Marco Polo found Islam established on the north coast of Sumatra by missionaries from the Coromandel coast; early in the 15th century the rulers of Malacca embraced it, and from there it was carried to Java, Borneo and other islands until (apart from the Philippines and Bali) almost all peoples of Malaysia became orthodox Muslims of the school of Shafi'i.

After the conversion to Islam, Arabic script with some Persian additions and three new letters took the place of earlier alphabets based on Sanskrit. Malay translations of the Ramayana and Mahabharata (*see SANSKRIT LITERATURE*) gave way to the early romances of Islamic heroes, and to Muslim stories as well as many Muslim treatises on religion from the Persian and Arabic. Malay in the 1960s is written either in Arabic or romanized script (*see MALAY LANGUAGE*).

Social and Political Structure.—Except in the state of Negri Sembilan in southwestern Malaya, where a matrilineal system derived from the Menangkabau (*q.v.*) prevails, Malays reckon descent and relationships bilaterally, through both male and female lines (*see DESCENT, SYSTEMS OR: Descent Systems in Asia*). Separation and divorce are relatively easy and common; husband and wife both have property rights in case of divorce or death. Women traditionally are influential in economic affairs, often carrying on trade and handling money matters. In the state of Kelantan in northeastern Malaya, about a quarter of the women earn a regu-

lar income and half are employed from time to time. In Malay villages or kampongs, often located along coasts or streams, the rather widely dispersed houses are separated by fruit trees and vegetable gardens. Village economy revolves round rice or rubber cultivation and fishing; men do the heavy work and women sell garden produce or cooked food and plant and harvest rice. Women also may weave or make floor mats and baskets, wash for alluvial tin or gold, tap rubber or teach in schools. Malays were not slow to plant rubber after the tree was introduced early in the 20th century and have adjusted to an industrial age.

Hinduism replaced Malay tribal chiefs with territorial rulers, to be advised by high court officials and governing through district chiefs. As incarnations of Hindu gods these rulers tended to wield absolute power until the British period. Its source forgotten, a political structure of 4 great, 8 major and 16 minor chiefs, whose numbers were determined by Hindu astrological notions, survived to modern times.

The main class division is between raja and commoner, though within both there are degrees based on birth, means, profession and personal characteristics. A ruler can marry a woman of any class though a raja woman loses social standing unless she marries a raja or a noble or distinguished man called a sayyid (e.g., a descendant of the prophet Mohammed). Before the British period, there were also slaves who might have been Malay debt-bondsmen, criminals, pagan aborigines or Africans brought by pilgrims to Mecca. As a Muslim, a Malay may marry a Christian or a Jew but not a polytheist or a pagan, unless the prospective mate converts to Islam.

All classes and national groups meet on the football field. Malays enjoy all forms of sport within their means: football, swimming, boat racing, physical drill. The tin and rubber capital invested in the Malay peninsula and archipelago under British protection provided revenue for an educational system extolled before World War I as unrivalled in Asia outside Japan, and for a medical service that abolished cholera, yaws, beriberi and smallpox, and confined malaria to remote rural areas. Better health and changed social and political conditions have stopped the notorious amok (homicidal mania); suicide among Malays is almost unknown and serious crime very rare. Far from conservative, Malays have welcomed innovation in custom, law, medicine, politics and dress, whether introduced by Hindu, Muslim or European.

Costume and Weapons.—Except for a bark loincloth and a blowpipe for killing game, the early Malay had neither clothes nor weapons. The men's coat of more recent times, bearing a Persian name, and the skirt (sarong) worn by both sexes came from India. Malay trousers may have been copied from the Chinese but have an Arabic name, as also has the velvet cap now worn by males; the rice planter's sun hat was brought from Yunnan and the elaborately tied headkerchief (now seen only on ceremonial occasions) probably was of Hindu origin. The usual jacket for women in the Malay peninsula is a coat of cotton or silk, knee-length and pinned with three brooches, and was introduced by the Portuguese in the 16th century. Women wear this jacket, or a more modern short jacket, with the sarong down to their ankles. For formal dress men wear trousers covered from waist to knee by the sarong. The most prized sarongs, heavily interwoven with gold thread, come from Batu Bara and Palembang in Sumatra, though silk sarongs of mottled patterns and interwoven with gold thread are made in Trengganu and sarongs of modern type in Kelantan. Most sarongs are imported.

The two-edged Malay dagger (kris) came from Java, though its prototype belongs to the Bronze Age culture of Dongson in Annam. It is never represented in early Indo-Javanese sculpture. By the end of the 13th century it had changed from a one-piece weapon to a dagger with a separate hilt of gold, ivory or wood, carved to represent Vishnu's bird the Garuda, or a Hindu demon Raksasa or rarely Hanuman the monkey-god. The blade became wavy to represent serpents or Nagas (dragons, spirits). Bronze knives of 1000 B.C. from An-yang in China and bronze knives from Ordos in Mongolia together with the kidney-shaped guard of the Scythian sword are identical with the shape and guard of the small Malay dagger known as the pepper crusher. The needs of piracy led to

the Bugi (q.v.) sundang (short swords with blades straight or wavy and cockatoo hilts). There is a great variety of wood knives. A finger knife for cutting rice stalk by stalk has a stone prototype unearthed in Tonkin.

MALAYALAM, one of the four literary languages of the Dravidian family, is spoken on the west coast of southern India. It developed out of Tamil between the 5th and the 10th centuries. In general it differs from Tamil in the absence of personal terminations in the verb. The colloquial and even more the literary language uses many words borrowed from Sanskrit. There were estimated to be 14,000,000 speakers at mid-20th century. See **DRavidian**.

(M. B. E.)

MALAYALAM LITERATURE. The literature of Malayalam (*Malayālam*), the language of Kerala (q.v.), though less ancient than the other three Dravidian literatures of south India (see **DRavidian**; **TAMIL**; **KANARESE LITERATURE**), has a history going back to the 13th century.

Early Period and up to the 19th Century.—Held to belong to the earliest times are ballads and folk songs, which are entirely indigenous. Two outside sources, however, contributed much to the development of the later literature: Sanskrit, which was the language of scholarship (see **SANSKRIT LANGUAGE**), and Tamil, which was the language of administration over a long period.

Rāmācaritam (13th century ?), a poem based on the *Yuddha-kāṇḍa* of the *Rāmāyaṇa* (q.v.), is the most important of the works influenced by Tamil; both in its grammar and its vocabulary it appears to be a mixture of Tamil and Malayalam. Less markedly dependent on Tamil are the works of a family of poets from Niraṇam in central Travancore who flourished in the late 14th and 15th centuries. Their works include translations of the *Rāmāyaṇa*, by Rāma Paṇikkar, and of the *Bhagavadgītā* (q.v.), by Mādhava Paṇikkar.

The importance of Sanskrit in the development of Malayalam culture lies not only in its position as a literary source, but also in its influence on the language. A special literary dialect arose containing a large admixture of Sanskrit and likened in its name, *Manipravāḷam*, to a necklace strung with "pearls and coral." (See also **INDIAN LITERATURE: Dravidian Literatures**.) It is described in detail in the *Līlātīlakam*, a 14th-century treatise in Sanskrit on Malayalam grammar and poetics.

Among the many *Manipravāḷa* works are *sandēśa kāvyas* and *campus*. The former, modeled on the *Meghadūta* of Kālidāsa (fl. c. A.D. 400; q.v.), are "message poems" consisting of two parts: the first giving an account of the circumstances in which the message must be sent and the route by which it should go; the second describing the heroine and the actual message. The finest extant work in this form, the *Uṇṇunīlī sandēśam*, was probably written in the 14th century, but the tradition of this type of poem has continued into the 20th century. *Campus* are elaborate compositions dealing with a given theme in alternating passages of verse and prose.

Though it was customary for writers of the Sanskrit school to use Sanskrit metres and figures of speech in their poems, local forms were not forgotten. An outstanding example of a work in a purely Malayalam metre is the 15th-century *Krishṇa gāthā* ("Song on Krishna"), usually attributed to Ceruṣṣēri Nampūtiri.

The greatest figure in Malayalam literature is Tuṅcattu Ezuttacchan (the second name meaning "father of letters"). Little is known with certainty about his life, though he is generally believed to have been born early in the 16th century. He was a poet in the Hindu tradition of *bhakti* (personal devotion to God: see HINDUISM). His main compositions, though based on Sanskrit works, show great originality of treatment. Thus his *Adhyātma Rāmāyaṇam* makes the hero, Rāma, an ideal figure both as man and god, and his *Mahābhārata*. (see MAHABHARATA) omits all episodes not strictly relevant to the story of the Pāṇḍavas.

Dance Drama.—Kerala is widely known as the home of Kathakali (see also DANCE; *The Orient: India and Pakistan*; INDIAN MUSIC). In this form of dance drama the actors concentrate on mime and gesture, while others recite or sing the verses. The verses belong to a literary genre known as *Aṭṭakatha*, which has been cultivated since the 15th century and takes most of its themes from the Purāṇas (*q.v.*). These stories also form the basis of the literature of Tullāl, a popular art form in which the story of the verses is told by recitation supplemented by the performance of a single dancer. Its literature began in the 18th century with the work of Kuñcan Nampyār, an innovator who satirized the society of his day in popular language.

Modern Period.—*Prose.*—In the 19th century, as a result of the work of Christian missionaries, the uses of prose were greatly extended. The process was accelerated by the production of textbooks for schools. Furthermore, the spread of knowledge of European literature led to attempts at literary composition on western lines. In 1889 there appeared the first novel in Malayalam, O. Cantu Mēnōn's *Indulēkha*, which portrays the effect of western ideas on an orthodox Hindu family. The historical novel was introduced by C. V. Rāman Pillai (1858–1922), who was later followed by the versatile historian, statesman and man of letters, K. M. Papikkar (*q.v.*; 1895–1963). The modern trend in the novel and short story, particularly during the years after Indian independence (1947), has been to concentrate increasingly on the life of the ordinary man, and this is nowhere better exemplified than in the work of Takazi Śivaśankara Pillai (1914–).

Poetry.—Before independence the work of poets writing in the various national languages gave impetus to the nationalist movement. The outstanding representative of Malayalam was Vaḷattōl Nārāyaṇa Mēnōn (1879–1958). Before he turned to patriotic verses he translated Sanskrit works and wrote a number of poems on Sanskrit models. Several of his compositions are religious in inspiration and often show a sympathetic understanding of the faiths of others. In his later years he took social justice as his theme, as did many younger poets.

All other branches of literature known in the west are cultivated, and Malayalam literature seems likely to flourish no less than when in earlier centuries it adopted Tamil and Sanskrit forms.

MALAY ARCHIPELAGO, also known as the East Indies and (formerly) Malaysia, the largest group of islands in the world, consisting of the more than 3,000 islands of Indonesia and the 7,000 islands and unnamed rocks of the Philippine group. New Guinea is usually arbitrarily included in the Malay archipelago while the Andaman and Nicobar Islands in the northwest and the Bismarck archipelago in the east are not. The principal islands and groups of Indonesia include Sumatra, Java, Borneo (Kalimantan), Celebes (Sulawesi), the Lesser Sunda Islands and the Moluccas, including Halmahera. The Philippines include the large islands of Luzon in the north and Mindanao in the south, with the Visayan group between. For political divisions, see the table in the section on Population.

The archipelago extends along both sides of the equator for a longitudinal distance of more than 3,800 mi. and is 2,200 mi. in its greatest north-south dimension. The festoons of islands with their enclosed seas are situated between the Pacific and Indian oceans.

Stretching from the mainland of Asia to Australia, the archipelago is separated from mainland Asia in the west by the 30-mi. Strait of Malacca, from Formosa in the north by the 100-mi. Bashi channel and from Australia by the 100-mi. Torres strait.

This island bridge is an area of physical and cultural transition between Asia and Australia. Because of its transitional nature and physical fragmentation, the region is one of great variety in physical landscape, climate, vegetation, animal life, land use and stage of economic development. The different peoples, their distinct cultures, myriad languages and many religions add to this diversity. The region has been subject to Indian, Chinese, Australian, Melanesian and European influences, all contributing to its cultural multiformity.

PHYSICAL GEOGRAPHY

Geology and Physical Features.—Structurally the Malay archipelago divides into three parts: the Sunda platform, the Sahul shelf and the area of recent tectonic activity which lies between the two. The Sunda platform is a stable continental extension of mainland southeast Asia. Most of the platform is covered by shallow seas averaging less than 25 fathoms. Borneo and parts of Java, Sumatra and associated islands are sections of the platform above sea level. These are areas of worn-down mountains of old metamorphic rock and are of complex geologic origin. The Sahul shelf, of which New Guinea and related islands are a part, is an extension of the Australian continent similar in structure to the Sunda platform and also covered by shallow seas. Between these stable continental platforms is a zone of recent tectonic activity: faulted and folded steep young mountain systems arranged in long mountain ranges or chains of islands. The main arc runs from Burma through the line of the Andaman and Nicobar Islands, forms the main ranges of Java, Sumatra and the Lesser Sunda Islands and then curves back through the Moluccas to Celebes. A circumpacific arc runs southward through the Philippines, through Halmahera and eastward along New Guinea. Other arcs run from the Philippines to Celebes and from the Philippines to Borneo. Around Celebes is a confused area of fragmented arcs and downfaulted basins.

Tectonic activity is characterized by frequent earthquakes, more than 1,500 a year occurring on the island of Banda in the Moluccas. Along the fracture lines associated with Tertiary folding are found a string of volcanic peaks, dating from the Late Tertiary and Quaternary. There are more than 300 cones, of which 50 are still active. Volcanic cones are scattered through the Philippines, northern Celebes and the Moluccas, and form the impressive chain of peaks which dot the Lesser Sunda Islands and march majestically down the length of Java and Sumatra. Eruptions are often of the explosive type but the benefits from volcanoes far outweigh the harm. The ejecta and ash weather into extremely fertile soil; the forest-covered permeable ash cones collect and store rainfall which is later made available for agriculture by surface streams.

Associated with the arcs are deep offshore trenches or basins. More than 20 are located in the area between the continental shelves and are occupied by deep seas, many over 2,500 fathoms deep. Coral growth reaches its greatest development in the Great Sunda reef which marks the edge of the Sunda platform off the east coast of Borneo. Coral reefs and atolls are found throughout eastern Indonesia and the southern Philippines.

The mountainous nature of the islands plus the generally high annual rainfall results in many short, steep-gradient rivers with erosive power. On the islands which lie on the continental shelves, the rivers deposit eroded material in the shallow surrounding seas and rapidly build extensive flood plains and deltas. Across these lowlands develop long rivers, such as the Musi in Sumatra, the Kapuas and Barito in Borneo and the Sepik and Fly in New Guinea. The islands which rise steeply from the deep seas between the continental shelves have little opportunity to build coastal plains and deltas in the surrounding deeps; level lowlands are limited and the rivers are usually short and steep.

Climate.—The Malay archipelago lies entirely within the tropics and, with the exception of the northern islands of the Philippines, within 10° of the equator, which bisects the major islands of In-

onesia. Because of this equatorial location, temperatures are high, averaging 80° F. The annual variation in temperatures is only a few degrees at the equator, but increases away from the equator to about 20° F. in northern Luzon. Annual variation in temperature is modified by the maritime influence of the surrounding seas. Temperatures are also modified by elevation, and many hill stations such as Baguio (*q.v.*) in Luzon and Prapat in Sumatra have been established in the highlands to take advantage of the lower average temperatures.

The variable element in the climate is rainfall, which ranges from more than 320 in. annually on exposed mountain slopes in Sumatra and Java to less than 20 in. in rain-shadow areas of western Celebes and the Lesser Sunda Islands. Most of the archipelago averages more than 80 in. of rainfall well distributed through the year, but the total decreases and the length of the dry season increases from central Java eastward through the Lesser Sundas and from Mindanao northward in the Philippines. Timor, in the Lesser Sunda Islands, has a dry season of more than six months per year. There is also great local variation in rainfall depending on elevation, relief and wind direction.

Another climatic element is the typhoon. More than 20 of these storms arise each year in the Southwest Pacific from July through November and then swing westward and northward, bringing violent winds and heavy rains to the Philippines north of Mindanao.

The region is usually under the effect of the doldrums or inter-tropical front, a zone of convergence of the northeast trade winds from north of the equator and the southeast trades from the southern hemisphere. Rising moist air in this zone of convergence results in heavy rainfall. This frontal zone of convergence moves north and south with the seasons. The proximity of the two continents of Asia and Australia further influences the wind pattern and consequently the rainfall pattern of the archipelago. During the northern hemisphere winter the northeast trades are reinforced by cold air masses from a high-pressure area over the middle of Asia. Thus reinforced, the northeast trades sweep over the islands toward the low-pressure centre in Australia and this is known as the northeast (or northwest) monsoon. In the northern hemisphere summer this pattern is reversed and the southeast (or southwest) monsoon results. Most islands receive rainfall from both monsoons.

Vegetation.—The natural vegetation of the islands reflects their transitional climatic nature and differences in total rainfall and its annual distribution. Throughout most of the area heavy rainfall and high temperatures result in continuous, rapid plant growth of great variety. Evergreen tropical rain forest with a great variety of large dipterocarps covers areas with ample rainfall. In drier areas there is a semideciduous monsoon forest, including such trees as teak and eucalyptus. This forest has seasonal rather than continuous growth. Other forest types include coastal forests (mangrove, nipa palms, pandanus), swamp forests and mountain forests. There are more than 150 species of palms, including the coconut, lontar, sugar, sago and areca palms, and bamboo is found in all areas. Large areas of the natural forest have been repeatedly cleared and dominated by cogon grass (*Imperata cylindrica*).

The flora of the Malay archipelago is probably the most varied in the world. More than 30,000 species of trees, shrubs and grasses belonging to more than 2,500 families have been recorded. This wealth of different species is the result of the heavy rainfall, long growing period, relief, variety of environments and the position of the Malay archipelago as a bridge between Asia and Australia. Mingling of the flora and the fauna of these two continents takes place in the islands. Some species have undergone a complex evolution as a result of geologic changes; island groups have been joined together, then separated, then rejoined, increasing the almost unimaginable diversity and complexity of plant and animal life.

Animal Life.—While the fauna of the archipelago is very rich, there are few large animals. Elephants, tigers, rhinoceros, wild cattle, tapir and orangutan are all part of the Asian fauna. They are unevenly distributed on the islands of the Sunda platform and indicate differing periods of connection between these islands. Of

the Australian fauna, kangaroos are found in New Guinea and other marsupials have moved beyond the Sahul shelf as far as Timor and Celebes. Some of the islands in between have endemic species, such as the anoa or dwarf buffalo and the giant monitor lizard or "dragon" of Komodo Island near Flores in the Lesser Sundas. Insects and birds have wider distribution, and the archipelago has probably the richest insect and bird life of the world. Particularly notable are the large longicorn beetles, the giant butterflies, the exotic birds of paradise, argus pheasants and myriad coloured cockatoos.

The transitional flora and fauna of the area early attracted the attention of naturalists and after extensive work in 1854-62 A. R. Wallace attempted to fix a line between the Asian fauna and that of Australia. Later work established that Asian species extend to the edge of the Sahul shelf and that the area between represents a zone of mixing, transition and local evolution.

For a more detailed discussion of the geography of the archipelago, see the articles dealing with separate islands or island groups such as JAVA; MOLUCCAS; SUMATRA; etc.

NATURAL RESOURCES

Agriculture.—The raw material wealth of the Indies is legendary and brings to mind rare spices and precious metals. Of the great variety of resources the most important is agricultural production, which provides employment for almost 90% of the population. Productive agricultural areas are based on favourable water and soil conditions. Most islands have ample water in all seasons, but the Lesser Sunda Islands from Sumbawa eastward are chronically short of water and large areas support only extensive grazing. Eastern Indonesia and the northern Philippines suffer severe seasonal drought.

Most upland soils are of weathered lateritic types of low fertility. Tree crops can be grown on some lateritic soils and shifting cultivators also make temporary use of these areas. The intensively cultivated irrigated rice areas are on the fertile alluvial soils of river valleys, deltas and coastal swamps. Basic volcanic rocks, ash and mudflows develop into fertile soils and support intensive cultivation in parts of Sumatra, Java and Bali.

The agricultural economy is varied. Nomadic hill cultivators raise subsistence dry crops of rice and corn in upland areas. The majority of the rural population are sedentary cultivators, usually growing irrigated rice, but sometimes corn, yams or cassava as their principal food crop. Many commercial crops such as rubber and tobacco, although introduced on plantations, are now grown by these sedentary small holders. The small holder produces most of the region's sugar, copra, pepper, nutmeg, spices, kapok, sago, tobacco and abaca. The plantations, introduced in the colonial period and located principally in Sumatra and Java, provide valuable exports of rubber, palm oil, sisal, cinchona (quinine) and tea, as well as some coffee, tobacco and copra.

Other Resources.—Forests provide valuable resources in timber and in resins, rattans and other gathered forest products. Timber exports are particularly important in the less-developed economies of Sarawak, North Borneo, Mindanao, Sumatra and Indonesian Borneo. Fishing and livestock production are important for domestic consumption only.

Petroleum is the chief mineral deposit of the archipelago, exploited in Sumatra, Indonesian Borneo, Brunei and West New Guinea. Production in the 1960s was only 3% of the world total but was important in the petroleum-poor areas of Asia. Tin mines on Singkep, Bangka and Belitung provide about 20% of the world's production. Deposits of bauxite are available in the Riuw archipelago and iron ore is mined in the central Philippines. Nickel is found in Celebes, and gold, chrome, manganese and copper in the Philippines. Coal resources throughout the archipelago are limited and of only fair quality; hydroelectric power potential is great although little developed.

Manufacturing is not greatly developed. Most important are handicraft industries and industries engaged in primary processing of agricultural and mineral products for export. Light manufacturing is expanding with spinning mills, paper, glass, soap and cigarette factories as well as some heavy industry. For a more

ANTHROPOLOGY

Prehistory.—The prehistory of the area goes back to Pleistocene deposits in Java, where several exceedingly primitive man-like beings, collectively known as *Pithecanthropus erectus*, have been found. In strata of the third interglacial appear Neanderthal-like humans, there known as *Homo soloensis*; while in still later horizons the fossil remains of Wadjak man seem to be related to the modern Australoids. On the mainland, skeletal remains give evidence of a Negroid physical type which in Late Paleolithic (Mesolithic) times was moving eastward into the Pacific toward New Guinea. No groups of large Negroes now exist in southeast Asia but remnant bands of Pygmy blacks, known as Negritos or Semang, are found in the Andaman Islands, the Malay peninsula and the Philippines. The Neolithic or New Stone Age introduced a new, non-Negroid physical type, possibly of a Veddalike people which once occupied the coasts from southern India and Ceylon eastward into the Malay archipelago. The Senoi (Sakai) of the Malay peninsula and minor groups in Sumatra, Celebes and some eastern islands of the archipelago appear to be related to this once widespread population. (See VEDDA; SENOI.)

Pygmies and Senoi.—The Pygmies are nomadic hunters and food gatherers who roam the jungles in small unorganized bands. They build only frail shelters and have scanty bark-cloth garments and few permanent possessions. The Senoi combine a limited agriculture with hunting, in which they employ the blowgun and poisoned darts. Their typical dwelling is a one-room structure raised high above the ground on piles, but some communal houses appear. Each settlement is under a headman—usually an elder—who exercises a limited authority. Considering the simplicity of their material culture, the Senoi have a rather intricate set of religious beliefs, including superior beings, wandering spirits and life after death. An unorganized group of individuals, called *halak*, deals with the spirit world by means of ceremonies and magic rites. The Senoi are of slight build, with rather long heads and angular faces. Skin colour is light reddish-brown; hair is dark and wavy and when worn uncut falls to the shoulders.

Proto-Malays.—The dominant population of the archipelago appears to have entered the area from the Asian mainland, probably by following the river courses which spread south and southeast from the Tibetan borders. The character of the country did not permit mass migration but there was a steady drift of a people much like the Malay, although of stockier build, with longer heads, heavier features and wavy hair. Because of their earlier appearance and their evident relationship to the Malays they are known as Proto-Malays. As they advanced they drove out or absorbed most of the aboriginal peoples. They were followed by an infiltration of a related but more definitely southern Mongoloid physical type. Amalgamation of the two produced the present-day Malayan. Isolated groups of the Proto-Malays are found on the mainland, while powerful tribes such as the Igorot-Ifugao of the northern Philippines, the Tenggerese of Java, the Toradja of the Celebes and in less pure strain the Batak of Sumatra still remain.

Malays.—The Malayan peoples spread over the mainland nearly to the borders of China, down the peninsula and out into the Pacific until they had occupied Formosa, the Philippines, Borneo and Indonesia. In later centuries, as they became competent seafarers, they went east to the coasts of New Guinea, while to the west they reached and colonized Madagascar off the coast of Africa. On the continent, except for the peninsula, they were eventually dispossessed or absorbed by incoming peoples such as the Mon-Khmer, Thai, Burmese and Assamese. Even there small islands of Malay-speaking groups still exist. Both Malay and Proto-Malay speak dialects of Malayo-Polynesian. (See MALAY LANGUAGE.)

The typical Malay is of slight build; men are about 5 ft. 4 in., women slightly shorter. They have brachycephalic heads, broad faces and noses of medium size. The Mongolian (epicanthic) fold of the eye is common; the chin is prominent. Skin colour ranges from olive to a reddish-brown; eyes and hair are dark and the latter ranges from straight to wavy. In both the Proto-Malay and the

Malay there is evidence of Caucasian mixture, probably due to crossing in the interior homeland.

The early Malayan kampong (village) was a small, largely self-sufficient unit. Bamboo and thatch houses of one or two rooms were raised high above the ground on piles. Close to the settlements were plots of rice, sweet potatoes, taro and in some places spices. Always coconut and betel nut palms were nearby. Industries consisted of weaving, mat- and basketmaking, handmade pottery and ironworking. Such a village was governed by a headman and a council of elders, but there was no higher, organized rule. Religion was highly developed around a belief in spirits, some good, some bad, some ancestral, some self-existing through time. Contact with the spirit world was through mediums who, in trances, conducted elaborate ceremonies for the general welfare. A rich folklore gave the background for the religious beliefs as well as for the near-universal practices of magic and head-hunting. Today the bilateral family, with inheritance and descent in both lines, is typical but a highly specialized variant type exists among the Menangkabau of Sumatra and in some other areas. There is found a clan and phratry system with inheritance and descent through the female line. In such areas the long house or community dwelling is prevalent. (See also MALAY.)

Other Elements.—Early in the Christian era Indian traders and petty princes entered the area in search of spices. Soon they set themselves up as rulers. Out of such beginnings empires arose (see *History*, below). Indian influence became dominant at the higher levels; elaborate courts were established together with Buddhist and Brahmanistic rites. The Indian epics, given a local setting, became the literature of the people. During this period there was some intermarriage between the newcomers and the upper-class natives. Into this situation came Arabian traders and teachers who in a short time succeeded in introducing the religion of Mohammed. Only in Bali did the Indian religion persist, but the cultural influence of India is still strong in the archipelago. In the Philippines, Christianity, introduced by the Spanish, resisted the spread of Islam.

The 15th century witnessed the appearance of the colonizing powers of Europe. Their influence has been great, especially as related to the economic life. In the Philippines, Spain wrought great changes and succeeded in establishing the only Christian population in Asia. European exploitation of such natural resources as tin and rubber called for manpower, a need answered in part by the introduction of Chinese and Indian labourers. Chinese contacts had begun in the East Indies by the 5th century but extensive immigration did not start until after the advent of the European powers. With settled conditions and opportunities for gain there was a great influx of Chinese, in some areas as traders and shopkeepers, in others as settlers or as coolie labourers. In the Malay peninsula and Singapore they were so successful that many remained and came to constitute about half the population. Another important element, especially in the peninsula, is the south Indian (Tamil), who came primarily as a labourer on the estates. Indians make up about 10% of the population. On the peninsula a pluralistic society emerged, composed of Malays, who are Mohammedans; Chinese, mostly Buddhists; and south Indians, with Hinduism dominant. Because of the differences in religion, language and economic activities, there has been little intercommunitarian and few community interests are shared. (F.-C. CE.)

HISTORY

The Hindu and Muslim Periods.—Indians—merchants and political refugees—arrived in Indonesia prior to the Christian era. Immigration continued for seven centuries but the number was never large. They intermarried with the Indonesian aristocracy and their descendants formed the governing class. The immigrants affected government and religion and exerted their greatest influence in Java and Sumatra. From there the new culture spread to Bali and the Moluccas, with some traces in Borneo and Celebes.

While the majority of the immigrants were Hindus, some were Buddhists. The two religions coexisted without persecution and provided the models for architecture and sculpture. Chinese traders arrived about the same time as the Indians but had little

influence on Indonesia. The two most powerful kingdoms between the 5th and 9th centuries were Sri Vijaya (Cridwidjaya) and Shailendra (Sailendra or Cailendra). The former, with its capital at Palembang in Sumatra, included part of Sumatra and the Malay peninsula and was a commercial and naval power. The Shailendra dynasty ruled in central Java during the 8th and 9th centuries; under it Indian art reached its highest development in, for example, the Buddhist temple at Borobudur. Later, eastern Java became the most powerful kingdom and in the late 13th century King Kertanagara conquered part of Sumatra, Borneo, Bali and several of the Moluccas. After an interlude of civil war and the intervention of a Chinese fleet and army sent by Kublai Khan, Vijaya (Widjaya) became king in 1294. He founded the empire of Majapahit, whose strength rested upon sea power and control of the spice trade. The empire finally collapsed in the late 15th or early 16th century. (See JAVA and SUMATRA for a more detailed history.)

The decay of Majapahit was hastened by the spread of the Muslim religion, introduced by traders. In 1292 Marco Polo visited the islands and found that the northern tip of Sumatra had been converted to Islam. From there it spread gradually through the islands until Hinduism survived only in Bali. The process of conversion was still in progress when the Portuguese arrived, and their efforts to substitute Christianity for Islam had little effect.

The Portuguese and Spanish.—In 1511 a Portuguese expedition under Antonio d'Abreu was dispatched to find a route to the Moluccas and Banda Islands, then famous for their cloves and nutmegs. The explorers reached Amboina and Ternate, after gaining some knowledge of Java, Madura, Sumbawa and other islands. In 1514 a second Portuguese fleet arrived at Ternate, which became the centre of Portuguese enterprise in the archipelago. In 1529 a treaty was concluded between Spain and Portugal by which the boundary between the Spanish and Portuguese spheres was fixed at 17° E. of the Moluccas; the Philippines were included within the Spanish sphere.

Portuguese traders frequented the coast of Java and established a trading port in Sumatra, but annexed no territory in either. Farther east they founded numerous forts and factories, notably in Amboina, Banda, Celebes and Halmahera. Ternate remained the seat of the governor of the Moluccas, the highest official in the archipelago. Portuguese power in the east was weakened by administrative corruption and by incessant war with native states, notably Bintang and Atjeh (Achin); bitter hostility was aroused by the attempts of the Portuguese to establish a commercial monopoly and to convert their subjects and allies.

The Dutch and English, 1595–1674.—The Dutch came to the east to avenge the injuries inflicted on their country by the Spaniards and to break the commercial monopoly of the peninsular states. They already possessed a large interest in the spice trade, for the Portuguese, having no direct access to the principal European markets, sent cargo to the Netherlands for distribution by way of the Scheldt and Rhine. The Dutch now sought to monopolize not only the distribution but the production of spices. The first Dutch fleet, under the command of Cornelius Houtman, reached Sumatra in 1596. In 1602 the Dutch East India company (*q.v.*) was incorporated, and for nearly two centuries played the chief part in the history of Indonesia. The Dutch were the stronger power at sea. They attacked the Portuguese in Ceylon (1602), and defeated a powerful fleet off Banda. In 1608 they forced the Portuguese to assent to an armistice for 12 years, and in 1609 Pieter Both was chosen as first governor general of Netherlands India. In 1611 the headquarters of the Dutch was changed from Bantam to Jakarta (*q.v.*), which in 1619 was renamed Batavia and became the Dutch capital. (The name Jakarta was restored in 1949.)

Meanwhile the English East India company extended its operations to the archipelago. After 1611 the commercial rivalry between the Dutch and British became acute, and commissioners met to arrange for co-operation between the Dutch and British companies and the maintenance of a joint fleet. But neither company could restrain its agents from aggressive action and many fresh causes of dispute arose. The treaty of defense lapsed in 1637. The

Dutch company opened up trade with Japan and China and prosecuted the war against Portugal with great vigour.

A new war between Great Britain and the Netherlands broke out and was terminated by the treaty of Westminster in 1674. Thenceforward the British company devoted its energies chiefly to the development of its Indian possessions, while the Dutch were left supreme in the archipelago.

The system of practical slavery enforced on the native races provoked an insurrection throughout Java, in which the Chinese settlers participated; but the Dutch maintained naval and military forces strong enough to crush all resistance, and by 1749 they were practically supreme in Java.

British Occupation, 1811–16.—The Netherlands Indies were at this time part of the Napoleonic empire, with which Great Britain was at war. A British naval squadron captured Amboina, Banda and Ternate in 1810, and in 1811 a strong fleet captured Java. Thomas Stamford Raffles (*q.v.*) was appointed lieutenant governor and introduced many important changes in the departments of revenue, commerce and judicature. In 1816 the Netherlands Indies were returned to the Dutch, in accordance with the treaty of Vienna.

Restoration of Dutch Power, 1816–1940.—The history of the archipelago was changed by Raffles' occupation of Singapore in 1819 to prevent the Dutch from acquiring a monopoly of trade throughout Malaya and with China. Questions between Great Britain and the Netherlands were settled by treaty in 1824. The Dutch were given freedom of action in Sumatra, while the Malay peninsula was recognized as within the British sphere of influence.

The extension of Dutch political power—notably in Java, Sumatra, Celebes, the Moluccas, Borneo, the Lesser Sunda Islands and New Guinea—involved several wars with various native states. A large expedition was sent to Lombok in 1894 and almost the whole of that island was incorporated in the Dutch dominions. A 30 years' war with Atjeh (see SUMATRA) began in 1873.

While the Dutch were consolidating their authority, other countries were acquiring interests in the archipelago. Immigration from China and Japan steadily increased. In 1841 Sir James Brooke (*q.v.*) established British sovereignty in northwest Borneo. In 1885 New Guinea was divided between Great Britain, Germany and the Netherlands. The Spanish-American War of 1898 resulted in the cession of the Philippines to the United States. Australian and Japanese trade in the archipelago was stimulated by the establishment of the commonwealth of Australia (1901) and by the Russo-Japanese War (1904–05).

The effect of World War I was to deprive Germany of the northern part of New Guinea, which was administered under mandate by the commonwealth of Australia. The division of Timor between Portugal and the Netherlands was reminiscent of the struggles of past centuries; the Dutch-Portuguese treaty in 1904 settled all outstanding questions (see TIMOR). Apart from the Philippines, the Malay archipelago was before World War II almost wholly in the hands of the British and the Dutch.

After World War II.—In World War II almost the entire Malay archipelago was brought under Japanese control. After Japan capitulated, the Indonesian republic was proclaimed on Aug. 17, 1945, and the transfer of sovereignty from the Netherlands to the United States of Indonesia took place on Dec. 27, 1949. On Aug. 17, 1950, the unitary Republic of Indonesia was proclaimed (see INDONESIA, REPUBLIC OF). The commonwealth of the Philippines obtained full independence on July 4, 1946 and became a republic (see PHILIPPINES, REPUBLIC OF THE). In 1963 the United Nations assumed caretaker status over Netherlands New Guinea (later West Irian) preparatory to assumption of administrative control by Indonesia in 1963. The former British colonies of Sarawak and North Borneo (Sabah) joined with Malaya and Singapore in 1963 to form the Federation of Malaysia.

(K. G. J.; C. H.; E. S.; G. W. O.)

POPULATION

The population of the Malay archipelago is more than 130,000,000, about 4.0% of the total world population (see Table).

The distribution of population shows great variation in density. The most densely settled parts of Java have a rural population of more than 4,000 per square mile while the adjacent island of Borneo averages less than 19 persons per square mile and has large areas without population. This reflects the productivity of land and many historical and cultural factors.

About 80% of the Indonesian and Philippine population is rural. After World War II and independence there was a pronounced movement to the cities, resulting in the rapid growth of such urban areas as Jakarta and Manila (*qq.v.*). Almost 40% of the population is under 20 years of age, accelerating the already rapid rate of annual increase of 2% in Indonesia and 3.4% in the Philippines. Population pressure is severe in parts of Java and Madura in Indonesia. In the Philippines northwest Luzon as well as several islands in the Visayan group suffer population pressure.

Migration, both voluntary and government sponsored, has resulted in the settlement of Javanese in southern Sumatra, around

Area and Population

Medan in northeastern Sumatra and along the southern coasts of Borneo. Filipinos from Luzon and the Visayan Islands have settled on sparsely populated Mindanao. Some have migrated outside the Malay archipelago: Indonesians to Malaya and Filipinos to the U.S., particularly Hawaii. But migration alone is an ineffective and temporary solution to population pressure. There are areas of the Malay archipelago where additional settlement is possible but continued rapid population increase will pose many problems.

(L. A. P. G.; F.-C. C.)

MALAY LANGUAGE is one of the Malayo-Polynesian (Austronesian) languages (*q.v.*). It is most closely related to Menangkabau in west Sumatra and perhaps connected with it by the varied dialects of south and west central Sumatra sometimes called Middle Malay. It is next most closely related with other Malayo-Polynesian languages of Sumatra, Java and Borneo and the

Cham languages of Vietnam. It is the native language of about 9,000,000 people distributed over the Malay peninsula, the east coast of Sumatra, the entire coast of Borneo and the smaller islands that lie between these areas, the Riouw archipelago, Bangka, Billiton, the Great Natuna Islands, etc. The local varieties differ noticeably from each other, but not as much as from the native Malay of Jakarta and that of Amboina.

Dialects.—The dialect of highest prestige is that of the Riouw Islands and the southern Malay peninsula. It is regarded as the basis of the standard Malay of the Malay peninsula and also of the Bahasa Indonesia ("Indonesian language") or Indonesian, which is the official language of the Republic of Indonesia. A Malay pidgin often called Bazaar Malay (*melayu pasar* "market Malay") developed as a lingua franca in the East Indian archipelago, probably before the arrival of the Portuguese. This pidgin varies somewhat locally. The variety used by the large Chinese colonies of Malaya and Indonesia is called Baba Malay. The formation of Bazaar Malay is no doubt due to the dominant position held successively by Palembang, Tumasik (old Singapore), Malacca and Singapore as the centre of trade between the East Indies and other countries. The Java form of Bazaar Malay was used by the Dutch as the colonial language. The movement for Indonesian independence adopted Malay in 1927. As the variety of Malay spoken by most of the members of this movement, the same Java form had a noticeable influence on present standard Indonesian. The Japanese sponsored an Indonesian more like standard Malay and this has continued as the Indonesian standard. The European words in standard peninsular Malay are mainly from English whereas those of Indonesian are from Dutch. Another difference is the increase in Indonesian vocabulary fostered by the Indonesian government.

Alphabets.—The earliest records in Malay are Sumatran inscriptions of the late 7th century in a Pallava (south Indian) alphabet. Such an alphabet is used in the so-called *renchong* script of southern Sumatra (Bengkulu, Palembang). With the coming of Islam in the 14th century, Malay became the local language of religious commentaries in converted Sumatra and in the Malay-speaking areas. An Arabic alphabet was developed for these commentaries and this orthography is still used in Malaya and parts of Sumatra for Malay. This alphabet is called Jawi (*huruf jawi* "Jawi letters"), perhaps because Java (Malay *Jawa*) dominated Sumatra and large parts of the peninsula at the time of the conversion.

An orthography with Latin letters was constructed by English scholars and has been used in some publications. The standard Indonesian orthography uses Latin letters, but since its basis was constructed by the Dutch, it differs from its Malay counterpart. After the modifications introduced by the Indonesian government the difference between the two Latin orthographies involved chiefly four letters: Malay *ch, j, ny, y* = Indonesian *tj, dj, nj, j*, respectively.

Structure.—The Malay of the southern peninsula distinguishes the syllabics *i, e, ē, ē, a, u, o, d* and the nonsyllabics *k, g, ng, ch, j, ny, t, d, n, p, b, m, y, w, r, l, s, h, q*. Syllabics appear nasalized (*tiān* "town") or unnasalized (*taon* "year"); *ē* appears in loan words (*bèk* "bag"). Likewise *k* is final only in loan words; romanized final *k* (= Jawi *qāf*) or apostrophe (= Jawi *hamzah*) corresponds to a glottal stop (*q*) in pronunciation; *r* is a velar spirant. In pronunciation *ē* appears for final orthographic *a*, and *e* and *o* for orthographic *i* and *u* commonly appear before final consonants (in disagreement with the standard orthography): *apē* "what," *baeq* "good," *bagos* "fine," orthographic *apa, baik, bagus*. Stress as well as pitch is part of the phrase structure and is conditioned by the shape of the words rather than the particular words.

Malay has a number of parts of speech. The chief ones are particles and full words, of which only the latter appear with attributes. The particles are exclamatory (e.g. *wah* "gosh"), prepositional (e.g. *di* "at," *kē* "to"), conjunctive (e.g. *jang* "that," *kalau* "if," *karēna* "because") and attributive (e.g. *chuma* "only"). The full words are nouns (e.g., *rumah* "house," *saja* "I") and verbals, the latter being further classified as adjectives (e.g.,

besar "big"), numerals (e.g., *satu* "one") and verbs (e.g., *beli* "buy," *pergi* "go"). As predicator a noun has the negative *bukan* (*itu bukan rumah* "that is not a house") whereas a verbal has *tidak* (*saya tidak pergi* "I did not go"). An adjective follows the noun it modifies (*rumah besar* "a big house"). A numeral precedes the noun it modifies (*satu rumah* "one house"). Usually there is a choice between a simple numeral as above and a compound numeral (*səbuah rumah* "a house"); in such cases the simple numeral calls particular attention to the number (*dua rumah* "two houses," *duabua rumah* "some two houses").

A noun is followed by a noun which modifies it; such a modifier is either descriptive (*orang melayu* "[person Malay] a Malay") or partitive-possessive (*rumah kawan saya* "[house friend my] my friend's house"). A passive verb is followed immediately by the agent (*itu dibeli orang* "[that bought person] that was bought by somebody"), although more commonly in Malay and less frequently in Indonesian a phrase with the preposition *oleh* is found (*itu dibeli oleh kawan saya* "that was bought by my friend"). Subject and predicate are in most cases invertible with a difference in emphasis; besides *dia kawan saya* "he is my friend," there is also the more emphatic *kawan saya dia*. Many common constructions of Malay resemble those of English (e.g., prepositional: *di rumah saya* "at my house"; verb goal: *beli rumah* "buy a house").

Words are simple, complex or compound. Simple words contain a single meaningful element: *nama* "name." Complex words contain at least two meaningful elements which differ as affix and root; e.g., *namakan* "to name." Compound words contain at least two meaningful elements neither of which is an affix: *rumah-makan* "(house-eat) restaurant." Longer sequences resemble one or the other type of word.

There is a fair variety of affixes, among which doubling (e.g., *nama-nama* "names") is to be counted. Nouns and adjectives are inflected for number (but noncompulsorily): *rumah* "house," *rumah-rumah* "houses"; *panas* "hot," *panas-panas* "hot" (pl.). Transitive verbs have a passive (*di-beli* "be bought") and active (*membeli* "buy") and a simplex which appears in commands (*beli* "Buy!") and in other constructions. Various affixes appear in derivation, such as doubling (e.g., with nouns "an analogue of": *jari* "finger," *jari-jari* "spoke," with verbs "diffusely, persistently": *berlari* "run," *berlari-lari* "run around, keep running").

Various affixes appear in derivation and very often these have ill-defined or varied meanings. There are two common suffixes: *-kan* (forms transitive verbs) and *-an* (*makanan* "food," *makan* "to eat"). The suffix *-i* is very rare in colloquial Malay (*lalui* "pass, traverse," *lalu* "go past") but is common in literary Malay and in very wide use in Indonesian. The number of prefixes is much larger (e.g., *ber-*, *tər-*, *pəng-*, *məng-*, *kə-*). Combinations of affixal elements are found that resemble the addition of a prefix and a suffix or prefix and doubling or the like without, however, showing the meaning of these as separate elements; e.g., *kəmauan* "desire," *mau* "want," *kəkuningkuningan* "tinted yellow," *kuning* "yellow," *səchəpəchəpatnja* "as fast as possible," *chəpat* "fast."

The combinations of elements in analyzable words are usually transparent. The chief exceptions are the active prefix (*məng-*) and others which behave like it. For these the shape of the combination depends on the initial of the following element as it would otherwise appear. If the initial of the base is *p*, *t*, *k*, or *s*, then a corresponding nasal appears at the seam (*potong* "cut," *məmotong*; *tipu* "deceive," *mənipu*; *kirim* "send," *məngirim*; *sapu* "sweep," *mənyapu*), otherwise the initial appears with the nasal it determines (e.g., *angkat* "lift," *məngangkat*; *bawa* "bring," *məmbawa*; *chari* "seek," *mənchari*).

MALAY LITERATURE. The history and geographical distribution of the Malay language is discussed in *MALAY LANGUAGE*; this article deals only with the literature itself.

Prose.—*Indian and Javanese Influence.*—No Malay writings in scripts of the Hindu period (4th-late 15th centuries) are extant, except a few inscriptions. One, of A.D. 1380, on the tomb of a Pasai princess, provides the first known example of Malay verse written in a Malay full of Sanskrit and Arabic. In Perso-Arabic script there are 15th-century versions of the *Ramayana* and *Mahabharata* (qq.v.), in a Malay sprinkled with Arabic loanwords; the *Ramayana* translated from a popular Javanese dramatic recension and the *Mahabharata* from a Javanese version written in *kawi* script, which died out c. 1400. In the 20th century Islam and the defeat of the shadow play by the motion pictures have killed interest in the two epics, but early Buddhist and Hindu influence survives in folk tales and in beast stories borrowed from the *Panchatantra* (a collection of Indian fables; see *BIDPAI, FABLES* or), the *Katha Sarit Sagara* ("Ocean of Story"), a 12th-century work, taken from an earlier collection, compiled in Kashmir by Somadeva, and Buddhist Jataka tales (see *JATAKA*). Java's large cycle of Panji tales, which date from the second half of the 14th century, was popularized as far as Cambodia by the shadow play. Part of one early recension, *Kuda Sumirang Sri Panji Pandai Rupa*, has been printed (1931 in Kelantan, Malaya, where many of the tales exist in manuscript) but a later recension in the 15th-century poem *Ken Tambuhan* is better known. Traces of one of the tales, *Chekel Waneng Pati*, a lengthy mythological romance interspersed with many comic interludes, occur in Malay folk romances, the *Hikayat Pelandok Jénaka* ("Tale of Willy Mouse-deer") and the *Malay Annals* (see below). The story of the buccaneer *Hang Tuah*, Malaya's only original romance until the end of the 19th century, is modeled on mythological stories of the Javanese Panji cycle.

Histories.—Between the 13th and 15th centuries Islam gradually ousted Buddhism and Hinduism in the Malay-speaking countries, first gaining ground in Sumatra and southern Malaya; the struggle between the old faith and the new in Sumatra is described in the *Hikayat Raja-Raja Pasai* ("Story of the Raja of Pasai," the oldest Malay history, and in its imitator, the finest Malay literary work, the *Səjarah Məlayu* (*Malay Annals*)). This, which must have been drafted in the port of Malacca in the 15th century, was revised in Johore in 1612. Only an author in as cosmopolitan a city as Malacca could have been familiar with Javanese, Tamil, Sanskrit and Persian words and with incidents from the *Ramayana*, the *Bhagavad Gita* (q.v.), the Panji tales, the Persian *Simabad Namah* and the Arabic account of Alexander the Great as a Muslim conqueror (see *ALEXANDER ROMANCES*). Other notable histories are the *Misa Məlayu*, a lively contemporary account of Perak (western Malaya) between 1742 and 1778; the *Kedah Annals*, largely compact of folklore and Buddhist myth; and two important accounts of Malaya in the 18th and early 19th centuries by Raja 'Ali Haji of the Riau (Riouw) archipelago. Such histories have been one of the two original features in a literature of translation, the other being the *pantun* (q.v.; see also *Poetry* below).

Islamic Literature.—With the acceptance of Islam, Malay authors started to translate numerous folk romances from Muslim India, some of them stories of warrior heroes, gods and demons others semihistorical, about such Muslim heroes as Alexander (from an Arabic source) and Mohammed (from Persian sources). Islam brought also famous cycles of tales: the *Hikayat Bayan Budiman* ("Tales of a Parrot") translated from Persian in the 15th century; the *Kalila dan Damina* (the Arabic *Kalila wa Dimna*), which exists in three Malay versions, two of them modern; the *Bakhtiar* cycle, a succession of stories told by an unjustly condemned prince in an effort to avert his execution, one recension of which is from the late Persian version and another, the *Hikayat Golam* (or *Azbakh*), from two Arabic adaptations of the Persian original. In modern times *Aesop's Fables* and some of the tales from the *Arabian Nights* have been translated into Malay. Many works on Islamic jurisprudence, dogma and mysticism have been written in Malay, some of the most scholarly by two

heterodox Sumatrans, the mystic Shams al-Din of Pasai (northern Sumatra) (d. 1630) and his contemporary Hamzah of Barus, the author of famous pantheist verses. An orthodox critic of both was Nur al-Din ibn 'Ali (d. 1658) who wrote the *Sirat al-Mustakim*, a treatise on Muslim conduct in everyday affairs, and the *Bustan al-Salathin*, a compilation of legend, history and science, as well as polemical treatises. About 1700 the *Risalah Hazar Mas'ail* (*Book of the Thousand Questions*) was translated into Malay from two early Persian texts. Between 1778 and 1824 four works by the Persian theologian al-Ghazzali were translated. Palembang (south Sumatra), the Riau archipelago and Patani (Pattani, now in southern Thailand) were centres for Malay theological authors. The first author to use a modern prose style was Munshi 'Abdullah (1796–1854), a Malaccan of Arab and Tamil blood who wrote his autobiography and an account of a business trip up the east coast of Malaya, and translated the Tamil version of Bidpai's fables into Malay. Since the second half of the 19th century Malays have continued the tradition of translation from Arabic and from Dutch and English, most of the works translated being educational.

Poetry.—The earliest Malay poetry was the *vers libre* of the magician's incantations, tribal songs and tags in folk tales that show the influence of the *Manimekalai*, a Tamil Buddhist classic dealing with the story of a popular goddess, Kannaki (or Pattini). More fashionable until the mid-20th century were long *sha'er* (poems) in stanzas with four rhyming lines, some of them novellettes in verse, others religious, others topical; the oldest is the 15th-century *Ken Tambuhan*. But far the best and most original verse is the pantun, a quatrain in which alternate lines have internal assonance as well as end rhymes. Modern Malay poetry, mostly Indonesian, has rejected traditional vocabulary and structure and copied European forms, often with great success.

(R. O. Wt.)

MALAYO-POLYNESIAN LANGUAGES (also known as the **AUSTRONESIAN LANGUAGES**) are a family of related languages with about 110,000,000 speakers in Madagascar, southern Vietnam, the Malay peninsula, Indonesia, the Philippine Islands, Formosa, New Guinea, the Melanesian, Micronesian and Polynesian islands and New Zealand. In pre-Columbian times this was the most widespread language family, extending from the Malay of Madagascar to the Rapanui of the Easter Islanders. The number of Malayo-Polynesian languages is more than 300 and perhaps exceeds 500 (depending upon the way in which languages are distinguished from dialects). They constitute 10%–15% of all languages in the world. The vast majority of speakers are in the Philippines and Indonesia, the island of Java containing somewhat less than half. There are four large countries in which a Malayo-Polynesian language is the official language or one of the official languages: Malay in Malaysia, Indonesian in the Republic of Indonesia, Tagalog in the Republic of the Philippines and Malagasy in the Malagasy Republic.

The Malayo-Polynesian languages are widely, but falsely, thought to be phonetically and grammatically simple. Malay and the Polynesian languages do have relatively simple phonemic systems, but their grammatical structures are not particularly simple. On the other hand a language like that of Yap shows complicated phonemic and grammatical structures.

The Malayo-Polynesian languages were once a single language. The original undifferentiated language became diversified locally, and the hundreds of Malayo-Polynesian languages are the result. The features of the original language, called Proto-Malayo-Polynesian, can only be inferred by comparing the modern forms.

Although the classification of the members of the family has not been completed, some close relationships seem to be observable. Most of the Philippine languages appear to be closely related to each other. With these are often grouped the Chamorro language of Guam and the language of the Palau Islands. The languages of western Indonesia (e.g., Malay, Achinese, Minangkabau, Batak,

Sundanese, Javanese, Balinese and some of the languages of Borneo) seem closely related to each other, to the Cham languages of southern Vietnam and to Malagasy. The languages of the Carolines with the exception of Palau, Chamorro (*see above*) and Yapese are closely related to each other and more distantly to Ponapean, Gilbertese and Marshallese. These are likewise closely related to the Polynesian language (*q.v.*). Since the languages of Micronesia and Polynesia are closely related to some of the languages of Melanesia (e.g., the Banks Islands and northern New Hebrides), and since those of the Philippines are probably related to those of western Indonesia, some scholars postulate two subgroups of Malayo-Polynesian: Eastern and Western. The languages of eastern Indonesia and of New Guinea resemble those of Melanesia, but are not clearly of either subgroup.

Not all of the languages in the vast island area demarcated above are Malayo-Polynesian. Most of the languages of New Guinea are non-Malayo-Polynesian. The Malayo-Polynesian area is limited to a large region near the isthmus connecting the north-west peninsula with the main body of New Guinea and the northern (both of the northwest peninsula and the main body) and eastern coasts. Non-Malayo-Polynesian languages are spoken in the northern two-thirds of Halmahera, in Alor and Timor in Indonesia and in the Solomon Islands in Melanesia.

The most likely next of kin of the Malayo-Polynesian languages is the Thai family. The generally accepted hypothesis regarding the Malayo-Polynesian migration states that it came from the continent of Asia via the Malay peninsula and the neighbouring chain of islands to the Pacific. The island of Madagascar was probably settled from Borneo in the first part of the 1st millennium A.D., not long after the Indians came to the Malay archipelago. The latter found the forerunners of the contemporary languages there, and these were no doubt already different from the forerunners of the Malayo-Polynesian languages elsewhere (except Madagascar). Thus the migration must have been well under way by then, perhaps for more than 2,000 years. The connection with the Thai family, however, is not beyond a reasonable doubt.

(I. DN.)

MALAY PENINSULA (sometimes called the **KRA PENINSULA**), in southeast Asia, is a long, narrow appendix of the mainland extending south through the Isthmus of Kra (latitude 10° N.) in Thailand to Cape Tanjong Piai (1° 16' N.) in Malaya for a distance of about 700 mi. (1,130 km.). It lies between the Andaman sea of the Indian ocean and the Strait of Malacca (west), the Singapore strait (south), and the Gulf of Siam and the South China sea (east). Politically it comprises the southwestern section of Thailand and the former Federation of Malaya (now the states of Malaya within the Malaysia federation), which occupies the main part of the peninsula. The ancient Chersonesus Aurea (Golden Chersonese), it has always formed a physical and cultural link between the mainland and the Malay archipelago. *See THAILAND; MALAYSIA.*

MALAYSIA, an independent federation in Southeast Asia, a member of the Commonwealth of Nations. Pop. (1965 est.) 9,392,040. The federation covers an area of 127,672 sq.mi. (330,671 sq.km.) and occupies two distinct regions separated by about 400 mi. (640 km.) of the South China Sea: (1) West Malaysia, on the Malay Peninsula, extending southeast from mainland Asia; this part of the federation includes the group of states that from 1957 till 1963 comprised the Federation of Malaya (the states of Johore, Negri Sembilan, Kelantan, Kedah, Trengganu, Selangor,

MALAYSIA

Perlis, Pahang, and Perak); and two former British colonial settlements, Penang and Malacca. (2) East Malaysia, comprising two former British crown colonies, Sarawak and Sabah (formerly called North Borneo), on the northwest coast of the island of Borneo.

West Malaysia is bordered on the north by Thailand and on the south, across the narrow Strait of Malacca, by the Indonesian island of Sumatra. East Malaysia is bordered on the south and east by Indonesian Borneo (Kalimantan), and across the Sulu Sea to the north and northeast of Sabah are the Philippine islands of Palawan and Mindanao. The capital of Malaysia is Kuala Lumpur (q.v.).

I. PHYSICAL GEOGRAPHY

A. MALAYA

1. Geology, Relief, and Drainage.—Malaya is a forested, mountainous area surrounded by wide, often swampy plains nearly at sea level except for the rocky islands that jut through them.

Malaya's mountains—the highest of which, Gunong Tahan, reaches 7,186 ft. (2,190 m.)—reaching only moderate elevations, carry vegetation on their summits. They are more massive and continuous to the north, diminishing in height and separating to the south where they continue as the hills of the Lingga and Riouw (Riau) archipelagoes. In mid-Malaya two sets of ranges meet: (1) a northern group lying on a north-northeast south-southwest axis; and (2) a southern group of lower mountains, similarly oriented, with extensions to the Trengganu coastal ranges.

The ranges have igneous cores intruded into late Mesozoic foliated systems; these are now so extensively eroded that granitic rocks are much exposed on the heights. Flanking these are steeply inclined limestones and calcareous shales, the former often standing out distinctively on otherwise smooth landscapes; such karst hills and their *polje* (known as *wang* in Malaya) are seen in Perlis, Selangor, and west Pahang. Substantial quartzite, conglomerate and shale beds occur at many levels. Across the eastern half of the peninsula are irregular exposures of the pre-Mesozoic Pahang volcanic series, including ash, pumice, and lava bed, with rhyolites and basalts. No volcanoes, active or extinct, have been found.

Landforms among the ranges include many infacing parallel scarps originating from the erosion of the anticlines to expose their igneous cores. Scarps of this kind are well developed in Pahang where they establish the alignment of the tributaries of the Sungai Pahang. One of these tributaries is the Sungai Bera, flowing north through the large Tasek Bera, the only natural lake in Malaya, which, partly by silting and partly by ingrowing vegetation, is little more than an overgrown swamp for much of the year. (*Tasek* or *tasik*, "lake"; *sungei*, "stream.") The Sungai Bera's headstreams in Negri Sembilan are being captured by the Sungai Muar, which flows into the Strait of Malacca. Because Malayan rocks are heavily weathered they are often concealed by thick (up to 100 ft. [30 m.]) covers of laterized material which impede geological survey; these consist of red and yellow clays interspersed with ironstone pans and the remnants of quartz veins. Beneath the coastal swamps are unconsolidated marine and river alluvials in places 450 ft. (140 m.) deep and extending as far as 40 mi. (65 km.) inland.

Alluvials at foot-of-hill locations and along valleys vary according to origin; clays, sands, gravels, peat (of old lagoons), and ironstone pans are common, white kaolins and coarse grits often adjoining the granite outcrops. Among the alluvials from granite-limestone contact zones occur metallic ores partially broken down by weathering and sorted by flowing water, whence most Malayan tin is mined (see below, *The Economy*). Tin-bearing gravels (cassiterites) vary in depth and thickness. Surface deposits have been exhausted; others lie as deep as 200 ft. (60 m.) below ground or are lodged among the solution cavities of subsurface limestone. Lode or vein tin is met only at depth and is difficult to find, so that it has not entered production except at Sungai Lembing in east Pahang. Through the coastal swamps and separated by infilling lagoons run lines of old sandpits (*permatang*) providing good wells for potable water and favoured by Malays as village sites.

Because of Malaya's narrowness and longitudinal ranges, its rivers are short, violent in flow in the mountains, sluggish and meandering on the coastal plains where equatorial vegetation presses into them. The rivers commonly have trellis drainage patterns among scarps and north to south alignments. The longest stream on the east is the Sungai Pahang, once significant as a highway for canoe-borne Malays, now traversing Malaya's least developed and most swampy area. The largest western stream is the Sungai Perak, itself little used but having as a tributary the Kinta, whose valley is the country's richest tin field.

Malaya's coasts are with few exceptions lined with mangrove swamps and have shallows extending far from shore, which offer easy approach for small craft but impede all modern shipping and deter harbour development. Heavy silting obstructs the approaches to river mouths. Even where a rocky outcrop occurs at the coast it is commonly isolated by difficult swamp-forest inland.

Both the Strait of Malacca and the South China Sea are shallow inundations of the Sunda Platform, the continental shelf underlying Southeast Asia and its islands, whose history through the

Quaternary glacial periods seems to have been a rising and falling of water levels, the present phase being one of the high sea level. Across their floors may be traced extensions of Malayan streams, evidence of a stage when they were tributaries to large rivers which once flowed northward roughly parallel to the present coasts. Tides on the west coast of Malaya derive from the Indian Ocean, where semidiurnal tides prevail; on the east coast, Pacific-type tides intersect with Java Sea tidal streams to produce semidiurnal tides with phases when days have a single high and a single low tide. Down the west coast a steady longshore drift from north to south induces heavy silting; one huge sandspit created by it in south Johore extends the Malayan coast well south of the southernmost corner of Singapore Island.

2. Climate.—Since Malaya extends between 2° N and 6° N and is surrounded by seas, its climate is equatorial, characterized by uniformly high temperatures through the year (a mean of 27° C [81° F]). The ranges are so low that only a few peaks rise above the tree line, and at Cameron Highlands, the one hill station, the temperature is only about 5° below that of the plains. Greatest seasonal variation comes from the interplay of the north tropical and south tropical air masses, bringing wind change rather than temperature change. During the northern winter, winds from northeasterly points cover the peninsula; in summer, it is subject to winds from the southwest.

Seasonal raininess varies with exposure to these winds, both of which are warm and moist. Peak rains often occur during the transitional months between these wind seasons. The northeasterlies bring heavy rains and rough seas to the east coast, which is then subject to floods and very dangerous for shipping. Thunderstorms, often convectional, usually accompany the rains. During the southwesterlies small, intense, and short-lived squalls called *sumatras* move across the Malacca-west Johore coasts. Strong land and sea breeze effects are felt at many points on the plains. Many stations report more than 70 days a year of heavy rain more than $\frac{1}{2}$ in. [13 mm.], and totals from town stations are a few inches either side of 100 in. (2,500 mm.) per year. Alor Star has 90 in. (2,300 mm.) with maximums in October and April and the minimum in February; Kota Bharu on the opposite side of north Malaya has 122 in. (3,100 mm.) with a maximum in November and minimum in February. Kuala Lumpur, an inland and central station, has 94 in. (2,400 mm.) with maximums in October and April and a minimum in July.

3. Soils and Vegetation.—In addition to swamp and peaty soils, the Malayan surface shows many varieties of the transition between black forest soil and multicoloured laterites, the stage depending chiefly on the extent of leaching after the ground is cleared of vegetation. When clearing takes place in such a way that the forest soil and its humus content is lost, what remains is poor agriculturally and within a few years may become sterile. The exceptions to this are soils in valleys in which accumulate the finer particles from all the drainage basins, and those soils weathered from the Pahang volcanic series. This accounts for the early and continued agriculture by the Malays along the river banks and in the deltas; the richness of soils on the Pahang volcanic series has been recognized only recently, chiefly because they are less accessible.

(E. H. G. D.)

The natural vegetation of Malaya consists of the high, continuous evergreen rain forest. It comprises an enormous variety of trees, the tallest mainly belonging to the dipterocarp family, which furnishes most of the commercial timber of the country. Epiphytic plants, mainly orchids, aroids, and ferns, are a notable feature of the rain forests. About 800 species of orchid are known. A variety of lianas is also present, and their ropelike stems are a feature of the jungle. One group, the rattans, have exceedingly long, tough, flexible stems, and climb by means of small recurved thorns on the prolonged leaf tips. Rattan forms the basis of an important furniture-making industry and is used for a variety of other purposes. The largest known flowers, species of *Rafflesia*, are found parasitic upon the woody vines of certain lianas.

Large bamboos grow in the lowland and foothill forest and are used by the aborigines and country people for making containers and rafts for river use and in house building. Palms are abundant

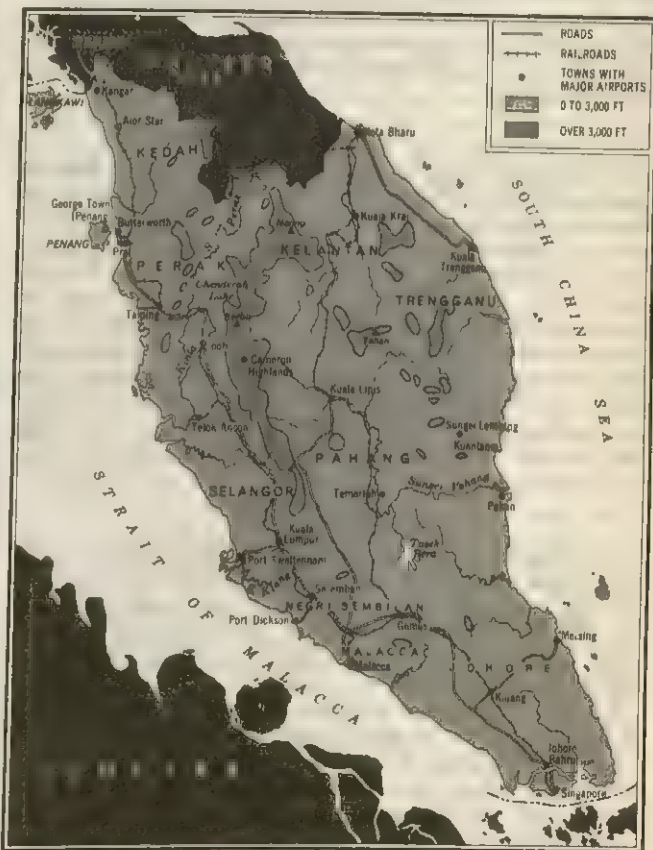

and varied. More than one-half the country is still covered by forest of this type. The mangroves of the coastal belt form forests of very distinct type, which are valuable as a source of firewood, and on the sandy shores coconut palms and casuarina trees are the main form of vegetation.

4. Animal Life.—Zoologically, Malaya has more affinity with Borneo, Sumatra, and Java than with the Asiatic continent, a circumstance derived from the fact that during the Ice Age the whole Sunda shelf was continuous land. Elephants are still fairly numerous, and the large blackish-gray wild cattle called gaur or seladang are found in the more extensive forested areas. Two species of rhinoceros are listed in the fauna, the larger of which, the Javan rhinoceros, may be extinct; the two-horned Sumatran form still exists in small numbers in the remoter hilly areas. The strange parti-coloured Asiatic tapir is found, and sambar, muntjac (barking deer), two species of mouse deer, and two of wild pig are among the other ungulates. Carnivores include tiger, leopard (mostly the black variety), clouded leopard, and a variety of smaller cats and civets. The large black siamang and two smaller forms of gibbon represent the anthropoid apes, and there are five species of monkeys. There is a single lemuroid, the slow loris; the primitive primates called tree shrews are common.

Of the smaller mammals, bats and rodents are present in great variety, including the large flying fox whose wing span may exceed four feet, the flying squirrel, and the so-called flying lemur, or cobego, whose affinities among the mammals are obscure.

Birds are numerous and varied. Bulbuls, tiny sunbirds, brilliant kingfishers, and the black and white magpie robin are familiar garden birds; a host of others, many seldom seen, live in the forest. Notable among these are the large grotesque hornbills, the magnificent argus pheasant, and the brightly coloured trogons and pittas.

Reptiles include the estuarine crocodile of the coastal mangrove and the Malayan garial of the inland swamps. Snakes are numerous. Only a small number of these are venomous, and known deaths from snakebite are rare; of those that do occur the majority are caused by sea snakes. The largest snakes are the reticulated

WEST MALAYSIA

python and the hamadryad or king cobra, the latter the largest venomous snake in the world. Among the most remarkable reptiles are the flying lizards, which glide from tree to tree as the flying squirrels do. The most familiar reptiles are the little house geckos, which astonish newcomers by their ability to run upside down on the ceiling.

A very large variety of fish is found in the surrounding seas and in the ditches, lakes, swamps, and rivers. Important fisheries exist all around the coast. Insects and other invertebrates are diverse beyond computation, and many groups are imperfectly known. As an example of this diversity, there are nearly 950 species of butterflies in the country.

The Taman Negara National Park, the largest of several wildlife reserves, is situated on the east side of the main mountain range; it includes the isolated Gunong Tahan (*gunong*, "mountain").

(M. W. F. T.)

B. SABAH

Sabah, the northernmost section of the great island of Borneo (*q.v.*), has a strongly irregular coralline coastline of 900 mi. (1,450 km.). The area is dominated by Mt. Kinabalu (13,455 ft. [4,101 m.]), the greatest mountain massif in southeast Asia, which appears on the coat of arms of Sabah and is the spirit homeland for the indigenous Dusun (Kadazan) people. Kinabalu has a specialized fauna and flora on its upper levels, which are formed of nearly bare black granite. Trus Madi (8,500 ft. [2,590 m.]), to the south, is the second highest mountain, in a great tangle of ranges which serrate the interior; there are, however, a series of alluvial upland plateaus stepped down from Ranau through Tambunan southward to Keningau and the Padas River, which are fertile and closely irrigated by the inland Dusuns. Unlike the other Bornean territories, Sabah has only one great river, the Kinabatangan, that is, navigable far inland. Travel is therefore predominantly overland, by jeep, pony, buffalo, or on foot, and is often arduous. Several deep bays provide good ports: Victoria on the island of Labuan (just off the west coast), Jesselton, Kudat, and Sandakan (the centres of the export trade), and Tawau near the Indonesian border. Temperatures on the coastal belt vary annually from 18.8° to 31.1° C (66° to 88° F). Rainfall, heaviest during the northeast monsoon from October to February, ranges from 60 in. (1,525 mm.) in the interior to 180 in. (4,572 mm.) on the coast.

(T. Hn.)

C. SARAWAK

This tropical state, lying south of Sabah on the west coast of Borneo, can be divided into three major physiographic zones: an alluvial and swampy coastal plain; an area of rolling country intersected by mountain ranges; and a mountainous region in the interior, the highest peak of which is Gunong Murud (7,950 ft. [2,423 m.]). There are numerous rivers, the largest being the Batang Rajang (*batang*, "stream"), which is navigable by small coastal steamers for 160 mi. (260 km.) upstream. Approximately three-quarters of the total land area is covered by primary rain forest. Rainfall varies between 120 and 160 in. (3,050 and 4,065 mm.) a year over most of the area, with the heaviest falls taking place between October and March. Temperatures range from 22° C (72° F) to 31° C (88° F).

(S. L. Str.)

II. THE PEOPLE

The Malaysian population was estimated in mid-1965 at 9,392,000, of whom 8,039,040 lived in West Malaysia, 835,000 in Sarawak, and 518,000 in Sabah. About 60% were under the age of 21. The last census figures were: West Malaysia 6,278,758 (1957), Sarawak 744,529 (1960), and Sabah 454,421 (1960). The first Malaysian census was to be taken in 1970.

The official language of Malaysia is Malay. Islam is the state religion, but freedom of worship exists for all faiths.

1. West Malaysia.—West Malaysia has three main population groups, each with its own cultural, linguistic, and religious background. Half are Malays, just over one-third are Chinese, and more than one-tenth are Indian or Pakistani. There are also about 46,000 aborigines, and Eurasians, Europeans, and others total 2%

of the population. Harmony has been a conspicuous feature of the social scene, although there has been little intermarriage among these varying groups. The mixture of peoples is the result of a flow of migratory pioneer labour between 1875 and 1910 when the modern pattern of the economy was being established. Immigration later became settled and has long been strictly controlled. Between 1911 and 1959 the population almost trebled, and it has continued to grow rapidly. If the 3% annual rate of natural increase of the mid-1960s continues, the population will be doubled in 24 years, a problem which is engaging the attention of the National Family Planning Board.

The communities tend to have separate economies. The indigenous Malays, who predominate in the east coast states, are scattered, mostly in small rural hamlets (*kampongs*), but they have been encouraged to enter industry and commerce. The Malays also form a large part of the executive civil service. Nearly two-thirds of the urban population are Chinese, active in every form of commercial enterprise, shopkeeping, and industry. Plantation labour is mainly Indian, and Indian workers also largely staff the railways. All communities are represented in the professions, their services not being on a racial basis.

Kuala Lumpur, George Town (Penang), Ipoh, Klang, and Johore Bahru have populations of more than 100,000, and 40 towns have more than 10,000.

2. East Malaysia.—In Sarawak and Sabah the registration of births and deaths is incomplete, and the intercensus estimates of population must be treated with reserve. Both states have a variety of peoples. In Sarawak the Ibans, or Sea Dayaks (a misnomer), are believed to be the largest group, numbering over 250,000, but they may have been overtaken by the Chinese. Together these two groups form more than 60% of the population, followed by Malays (17%), Land Dayaks (nearly 8%), and Melanau (6%). Other indigenous peoples, some nomadic and scarcely known, number about 50,000. Dayak are found in all parts of the state. Most of the Chinese are settled in the three large towns—Kuching (*q.v.*; 50,579 at 1960 census), Sibu (29,630), and Miri (13,350)—in the trading centres, and in pepper gardens and small rubber plantations; they are also Sarawak's shopkeepers.

Sabah's chief towns are the capital, Jesselton (21,719 population in 1960), and Sandakan (28,806). There are three main population groups: the Kadazans (formerly known as Dusuns), who are closer to the Visayan and Sulu peoples of the Philippines than to the Dayaks, number more than 150,000, representing more than one-third of the whole; there are also 110,000 Chinese and 60,000 Bajaus. The Kadazans are peasant farmers who live along the west coast and in the plains of the interior. The Muslim Bajaus raise cattle and ponies. The Chinese control most of the trade and work the timber concessions. The 1960 census enumerated 11 indigenous tribes (there are other smaller groups), mostly fishermen and farmers, who form with the Muruts one-fifth of the

CAMERA PRESS—PIX FROM PUBLIX

SCHOOLCHILDREN OF SARAWAK PARADING IN CELEBRATION OF THE END OF THE SCHOOL TERM AND THE BEGINNING OF THEIR HOLIDAYS

population. The larger tribes include the Ilanuns and Sulus, feared as pirates in the mid-19th century from the Philippine Archipelago to the Bay of Bengal. The Muruts, who are found in the more inaccessible parts of the interior, collect jungle products and practice a shifting cultivation.

III. ARCHAEOLOGY OF MALAYA

A fairly complete Stone Age record has been found in Malaya, the Paleolithic, Mesolithic, and Neolithic all being represented. The Paleolithic Tampanian culture was discovered by H. D. Collings in 1938 at Kota Tampan on the Sungei Perak. In a raised terrace Collings found large, crude stone tools, mainly roughly made choppers and flakes; later research suggests that the terrace was formed in the second glacial period of the Pleistocene. Although this dating is rather earlier than that of the Javanese Pajitanian, the Soanian of India, and the Choukoutienian of China (all generally regarded as Middle Pleistocene), the Tampanian probably belongs to the same complex of early Asian cultures. No fossils have been found with the Tampanian artifacts, but if correlation with the Choukoutienian is correct, their author was probably a being of the *Pithecanthropus* type.

The Mesolithic is represented by remains in midden deposits in the floors of caves and rock shelters. The similarity of this culture to the Hoabinhian, classically developed at Hoabinh in Indochina, is so close that the same name has been applied to it. Abundant stone tools made from river pebbles are found in the middens, some being "biface" tools in which opposite sides of the pebble are entirely flaked away, others "uniface," having one side left intact. Animal bones, evidently food remains of a hunting people, are of existing species, suggesting a postglacial age, and associated human remains are of a type close to the present day Melanesians. An interesting feature of these Hoabinhian remains is the presence of soft red hematite, pieces of which often show signs of rubbing or grinding. It has been suggested that it was used to make red pigment for ritual blood symbolism.

In Province Wellesley, not far from the coast, accumulations of molluscan shells are associated with artifacts of Mesolithic type, human remains and, again, red hematite. They are clearly food remains of a people who lived near the shore, the sea having since retreated. Evidence from a human lower jaw suggests that, like the Hoabinhian people, they were of a Melanesian type.

The Neolithic is represented by the Quadrangular Adze culture, whose characteristic artifact is a polished stone adze with quadrangular cross section. These adzes are often found by the country people in river beds after floods and in the course of alluvial mining, but the richest finds have been in rock shelters used by the Neolithic people as burial places. The burials were accompanied by grave furniture consisting of stone tools and ornaments, ornaments of shell, and diversely shaped and decorated pottery vessels. Stone bark cloth beaters have also been found, indicating that bark cloth was used for clothing.

There is no evidence of an indigenous Bronze Age, but bronze socketed celts of a type widespread in Europe and Asia and some artifacts of the Dong-son culture (two ornamented bronze drums and three large bells) have been found.

The richest site representing the Early Iron Age is at Kuala Selinsing on the coast of Perak. There I. H. N. Evans found large numbers of beads of glass and semiprecious stones, a cornelian seal inscribed with Pallavan script, quantities of pottery, and some gold ornaments. These were accompanied by human burials in dugout canoes. Evidence from the beads and pottery suggests that the site was inhabited from about the 8th to the 11th or 12th century A.D. Inland, peculiarly shaped iron artifacts, and graves lined with granite slabs and containing beads and pottery, probably belong to the same period.

Evidence of early colonization from India, extending from about the 4th to the 12th century A.D., was found and reported on by H. G. Quaritch Wales. Most of the sites are in Kedah, one of the northernmost states, and finds include a fine bronze image of the

Buddha of the Gupta Age (5th century), a clay tablet inscribed in early 6th-century Pallavan script, and a bronze casket containing a treasure of miniature gold objects.

The National Museum of Malaya (in Kuala Lumpur) and the Perak Museum house collections of Malayan archaeological and ethnographic antiquities.

IV. HISTORY

A. MALAYA

1. Early History.—Descending from the Yunnan province of China, bark-clad Mongoloid tribesmen destined to become by intermarriage with other peoples the deuterio- or civilized Malay reached the Malay Peninsula and Archipelago between 2000 and 1500 B.C. They lived in houses on piles, with bamboo flooring, and cultivated bananas, gourds, sugar cane, and coconut palms; rice and millet provided them with cereals and fermented drink. They domesticated the buffalo and pig. Many kinds of trap and noose were employed for catching game. They paddled catamarans and used fishing traps of bamboo and wood. They were headhunters and erected megaliths to dead chiefs.

Then about the time of Christ this primitive people came under the influence of two foreign peoples. One was the Yuë, whose traders left bronze drums on the Tembeling River in Pahang and near Klang in Selangor and bronze adzes along the Kenaboi River in the Jelebu district. They taught the craft of weaving cotton and decorating it by the tie-and-dye method. They bequeathed a large vocabulary to Malaya's aborigines, but the art they brought, termed Dong-sonian after the site of a cache in Indochina, did not become established in the peninsula, partly because most of the materials for making bronze were absent but chiefly because the nearness of India soon caused Indian influence to swamp all others.

India gave to the Malays alphabets, religions, astrology, medicine, law in place of tribal custom, a political system, literature, and the crafts of goldsmithing, silversmithing, and silk weaving. For at the beginning of the Christian era the luxury of the Persian and Roman empires called for the gold and spices of the East. The construction of large Indian ships on the Persian model, the discovery of the Arabs' secret knowledge of the monsoon winds, and the rise of Buddhism, with its disregard for caste prejudices against crossing the sea, all stimulated Indian voyaging to Indonesia and Malaya. The first important Hinduized kingdom in southeast Asia was Fou-nan (a Chinese transcription of *Funan*, "mountain"), which covered the north of Malaya, Thailand, and Indochina. Probably one of its subject kingdoms was Langkasuka, according to the Chinese a walled, Buddhist kingdom in northern Malaya in the 2nd century A.D.; it must have straddled the land routes to Thailand and Indochina and was trading with China by A.D. 575.

Sanskrit inscriptions of the 4th century A.D. in Kedah and Province Wellesley, as well as Buddhist bronzes from Kedah and Perak, attest that the Indian pioneers in Malaya were Buddhists. Except for an interval when Fou-nan became Shivaite Hindu, Mahayana Buddhism predominated until the fall of Fou-nan's successor in northern Malaya, the Buddhist kingdom of Sri Vijaya (7th-14th centuries A.D.).

Sri Vijaya, the San-fo-ts'i and Chi-li-fo-che of the Chinese and the Zabag of the Arabs, long controlled the Sunda Strait from its capital at Palembang and the Strait of Malacca from Kedah. Its stranglehold on commerce led to constant fighting with Java from 992 onward and to several attacks on Kedah by the Chola kings of southern India. These culminated in a great raid in A.D. 1025, when the Chola ruler Rajendracola Deva I claimed the conquest of Palembang, Jambi in Sumatra, Langkasuka, and Kedah, though Sumatra and Malaya were too far away for the raider to maintain his suzerainty. In the 13th century Sri Vijaya's Sumatran rival, Jambi (or Malayu), broke away and gave its name to the Malay people. Between 1338 and 1365 Java's Hindu empire, Majapahit, raided Sumatra and Sri Vijaya's dependencies in Malaya. The Tais invaded Malaya from the north, and finally missionaries of Islam gave the death blow to the old order in Malaya, Sumatra, and Java.

2. The Kingdom of Malacca.—The next kingdom of consequence in Malaya was Malacca, founded c. 1403 by a Palembang prince who had married a Javanese princess and ruled Tumasik or Temasek (Singapore) with the title of *parameswara*. The Siamese then owned the island and the *parameswara*, having got it by killing the Siamese governor, eventually had to flee. Malacca had fresh water and a harbour for ships; it lay remote from Siam with possibilities of capturing some of the trade enjoyed by Kedah when part of Sri Vijaya. Kedah, though then subject to Siam, still claimed suzerainty over the western Malay states down to Malacca, while at the same time an important Sumatran Muslim state, Pasai in Atjeh, claimed suzerainty over Kedah. Perhaps it was this that led the *parameswara* in old age to marry a Pasai princess, become a Muslim, and take the title of Megat Iskandar Shah. His successor reverted to the title of the Buddhist kings of Sri Vijaya, namely maharaja, and established a constitution on the Indian pattern adopted by Fou-nan.

About 1445, however, Muslim Tamil merchants murdered the rightful heir to the Malacca throne and elevated his younger brother (whose mother was a Tamil) with the title Sultan Muzaffar Shah. Malacca then began its conquest of the whole of Malaya, including Patani and Kedah, and fought off several attacks from Siam. It also subjugated Sumatran states across the strait. From conquered states it exacted tribute of gold, tin, or fighting men; in exchange, its fleets protected them. The port had one quarter for Chinese merchants, another for Indians, and another for Javanese. Inhabited by seafaring Malays ("sea gypsies"), Malacca had to import rice and other foodstuffs. A spurt in Chinese overseas trade and the mercantile activities of Muslim Indians led the Portuguese adventurer Duarte Barbosa to call it "the richest seaport with the greatest number of merchants and abundance of shipping to be met in the whole world." Its court was a centre of culture old and new.

3. Portuguese and Dutch Conquests.—In 1498 Vasco da Gama landed in India, and by Aug. 1, 1509, a Portuguese fleet had entered the Malacca roads to reconnoitre. It had to retire, but in August 1511 Afonso de Albuquerque captured Malacca. Portugal's small population made it impossible to hold extensive colonies, so Albuquerque built a great fort there called "A Famosa," established a new currency, executed a Javanese headman for trying to corner rice, and then left Malacca to a governor. Forces of the exiled Malay sultan Mahmud and his allies frequently cut off the port's food supplies and even invested the fort. The Portuguese insistence on monopolies led to the creation of the Sumatran pepper-trading state Atjeh (*q.v.*). The Javanese and Atjehnese (Achinese) both attacked the fort. Tomé Pires (who had been Albuquerque's druggist) lamented the absence of qualified administrators and expert traders and condemned the officials as "arrogant, undisciplined, and dissolute." St. Francis Xavier condemned their corruption: It was recorded that the captain of the fort got £50,000 a year from perquisites and illegal private trade.

In 1602 the Dutch East India Company was created and in 1619 Jakarta in Java became its capital under the name of Batavia. By 1635 the Dutch were capturing or intercepting all Portugal's ships and had ruined the trade of Malacca. In January 1641 after a siege of 5 months and 12 days the Dutch wrested the city from Portugal. Malacca as a centre was supplanted by Batavia. Under Portugal Malacca's population was estimated at 20,000; a quarter of a century of Dutch occupation reduced it to 4,884 persons. Like the Portuguese, the Dutch tried to secure the sale of cloth and the purchase of tin and spices at their own figure, but their monopoly was challenged by Atjehnese, Javanese, and Indian traders. The cheapness of Indian textiles won them a large market in Malaya and the archipelago. Finally in 1786 the founding of the British free port, Penang (later George Town), ended Dutch monopolies.

4. Britain and the Straits Settlements.—As a rival to Dutch Malacca, a port of call between India and China, and a repair station for warships, the island of Penang was rented by the English East India Company in 1786 from the sultan of Kedah at the instance of a young trading captain, Francis Light. The sultan stipulated that the company should promise to help him against the

attack of any enemy from the interior, meaning Selangor and Siam. Light pledged this military aid, and Penang was occupied by the British. But William Pitt's India Act of 1784 required the sanction of the British government for any agreement that might lead to war, because (after the loss of the American colonies) "schemes of conquest and extensions of dominions" were "repugnant to the wish, the honour and policy of the nation." The British government refused to implement Light's assurance to the sultan. However in 1791 a treaty was signed guaranteeing Kedah an annual rent for the island (paid down to modern times).

Besides Penang (with Province Wellesley, which was ceded by Kedah in 1800) there were two other Straits Settlements, Malacca and Singapore. Fear of French warships capturing Malacca led to the British occupying it in 1795, and though after Napoleon's downfall it was returned to Holland it was later ceded to Great Britain by the Treaty of London (1824). In 1819 Sir Thomas Stamford Raffles (*q.v.*) had taken the first steps to acquire an almost uninhabited mangrove swamp, Singapore, from the *de jure* (though not *de facto*) sultan of Johore, and in 1824 (fear of Dutch action against it removed) the whole island became British territory.

The Straits Settlements were the property of the East India Company until after the Indian Mutiny when the company was abolished and the India Office took control (1858). In 1867 agitation by British and Chinese merchants led to the three settlements being proclaimed a crown colony, when for the first time non-officials, British and Asian, obtained a voice in their government. In 1946 Penang and Malacca ceased to be British possessions, being included in the abortive Malayan Union and later, in 1948, in the Federation of Malaya. Singapore, which remained a crown colony after 1946, was granted internal self-government in 1959. In 1963 it became a state within the Malaysia federation, from which it seceded in 1965 to become an independent constitutional monarchy within the Commonwealth of Nations (*see SINGAPORE*).

5. The Malay States.—After 1511 the fugitive sultan of Malacca settled in the Riouw (Rhio) Archipelago, but driven out by the Portuguese he fled to Sumatra where he died in 1528. His eldest son, by a Kelantan princess, became Perak's first sultan; his second, by the daughter of a *bendahara* (principal minister) of Malacca, became sultan of Johore. In the north Kedah, Kelantan, and Trengganu became tributaries of Siam. Over the southern Malay states Johore claimed to be overlord until in the 17th century Bugis from Makasar occupied and ruled Selangor and in the 18th century Menangkabau princes from Sumatra created and ruled Negri Sembilan. The Bugis occupied Riouw also, and the sultan of Johore settled in the island of Lingga. His cousins, the two greatest chiefs of the broken empire, were cut off at Pahang and Johore and in the 19th century made themselves independent rulers. Except in Perak the old Malacca royal line had died out in 1699, and all later rulers of Johore and Pahang and Trengganu were of the Bendahara family.

The breakup of the Johore empire led to fratricidal wars among the Malay rajahs. Feuds also started among the secret societies of newly arrived Chinese tin miners, who took sides in the Malay civil wars. Merchants, British and Chinese, in the Straits Settlements begged the British government to intervene to protect their lives and property in the Malay states. Only a fear lest Germany might intrude upon the Malayan scene made Great Britain reluctantly decide in 1873 to consider the appointment of British residents in the Malay states, with their rulers' consent. The first treaty, signed at Pangkor on Jan. 20, 1874, with Perak followed the Singapore precedent in being made with a *de jure* but not *de facto* sultan. In 1874 residents were accepted by Perak, Selangor, and one of the Negri Sembilan, Sungai Ujong. By 1888 they had been accepted also in the whole of Negri Sembilan and in Pahang.

In Perak the tactlessness of the first resident in abolishing the feudal perquisites of chiefs without compensation led to his murder, a minor war, and the banishment of the *de jure* sultan. In Pahang one chief rebelled against the sultan for accepting British advice, and in the ensuing guerrilla fighting 40 were killed and 30 wounded. There was little resistance, however. Under British

sovereignty slavery was abolished. For the first time the rulers consented to admit non-Malays, British, Chinese, and Indians, to membership of state councils and to accept a British code in place of Muslim criminal law, with its sentences of mutilation for theft and of death for adultery. Land titles were issued giving security of tenure, and the revenue was employed for public services. In 1895, to secure uniformity of legislation and administration (and so to encourage foreign capital), the four states accepted federation. Soon the increase of capital expended on tin mining and on the newly introduced Pará rubber provided revenue not only for roads and railways but for medical and educational services, the advance of which was so rapid that before World War II the International Labour Office at Geneva reported that outside Japan they had no rival in Asia.

6. The Unfederated States.—After the British rented Penang from Kedah and refused to become involved in any war with Siam, Kedah was forced by Bangkok to conquer Perak. Weakened by that distasteful task Kedah was itself overrun by Siamese forces and the sultan driven into exile. In 1826, however, Siam acknowledged the independence of Perak and Selangor and undertook not to obstruct English trade in Kelantan and Trengganu. In 1862 Col. (later Gen. Sir Orfeur) Cavenagh, governor of Singapore, required Siam not to depose a friendly sultan of Trengganu and bombarded the sea front of Trengganu to secure compliance, disregarding Siam's claim to suzerainty. Sir Frank Swettenham, as governor of Singapore, also challenged that claim in 1902 by visiting Trengganu in his official yacht. He showed such eagerness to extend British protection over the Malay states under Siamese rule that the foreign secretary, Lord Curzon, described him as "a swashbuckler of a most truculent type."

There was some excuse for his eagerness. For £2,000 and 2,000 shares the sultan of Kelantan had disposed of 3,000 sq.mi. (7,770 sq.km.) of territory, with wide powers and privileges, to a police inspector, R. W. Duff, who hoped to emulate Raja Brooke of Sarawak (see below). The buying back of these powers and privileges was later to lead to costly litigation that hampered the state for years. The government of Trengganu was medieval, crime was rampant, and the peasants were downtrodden. In 1905 Kedah's indebtedness forced Siam to appoint a British member of the Indian civil service to superintend its finance and administration.

Meanwhile the entente cordiale of 1904 had removed the fear that if Great Britain extended its influence in northern Malaya, France might occupy Siam and damage British trade. In 1909, anxious to build a railway connecting Bangkok with the Malayan line to Singapore, Siam, in return for a loan of £4,000,000 at 4% interest and Great Britain's surrender of extraterritorial rights for its subjects in Siam, transferred to Great Britain Kedah, Perlis, Kelantan, and Trengganu, four states that had never brought Siam any revenue.

The last Malay state to come under British protection was Johore. In 1885 Johore undertook by treaty not to enter into engagements with any foreign state and not to alienate land to other than Asians or British subjects; Great Britain undertook to protect the state against foreign attack. The sultan had a constitution drafted by British lawyers, which was later taken as a pattern by other Malay states. By 1914 an increase of population and the development of the rubber industry made administration too complex for his subjects and the sultan accepted the appointment of a British general adviser. All Malay states south of Siam were then under the protection of Great Britain.

7. The Japanese Invasion.—That protection had always been taken as beyond challenge, with Singapore as the "Malta of the East," until on Dec. 7, 1941 (Dec. 8 west of the Hawaiian Islands), Japanese aircraft largely destroyed the U.S. fleet at Pearl Harbor and bombed Singapore, and Japanese forces were landed in Kelantan. A British naval attempt to halt that landing ended on Dec. 10 with the sinking of the battleship "Prince of Wales" and the battle cruiser "Repulse" in the Gulf of Siam. Japan had about 300 bombers and 800 fighters against 141 obsolete British aircraft, and that preponderance, with Britain's loss of control of the sea, meant that 150,000 Japanese crack troops could advance 550 mi. (880 km.) down the peninsula to Singapore at the rate of 10 mi. a

day, landing soldiers by sea in the rear of the defense. On Jan. 30, 1942, all British forces were withdrawn to Singapore Island, which, with its Johore water supply cut, fell on Feb. 15. Until 1945 Malaya was occupied by the Japanese. (See WORLD WAR II: *The War in the Pacific*.)

8. Developments After World War II.—When the Japanese were expelled, the British returned. Concerned at the cumbrousness of 11 governments in a small country, the British government decided to get the Malay rulers to transfer their sovereignty to the king of England and to accept a Malayan union. Sir Harold MacMichael was sent on this mission of virtual annexation and also to recognize on behalf of the king the four rulers who had succeeded to thrones since 1942. The rulers were told that the object of the mission was secret and not to be revealed to their subjects. They signed the required agreement but, finding that this high-handed procedure was denounced in the *Times* by retired civil servants and judges and in both houses of Parliament, the Malays started a mass movement of noncooperation. They formed a United Malays National Organization (UMNO) and for the first time learned their political power. The one good feature in a sorry business was that British army trucks helped to convey them to a mass meeting.

The government yielded and appointed a committee of Asians and British officials to recommend a constitution. This committee advised that instead of a union under a governor there should be a federation with a high commissioner and the novelty of an executive council. A prime minister and executive council were also to be appointed in each state. The federation was established in 1948. Later, in 1955, elections were introduced for a majority of the members of the federal legislature, and every seat but one was captured by the Alliance Party, composed of UMNO, the Malayan Chinese Association (MCA), and a Malayan Indian Congress under Tunku Abdul Rahman, barrister son of a Kedah sultan.

This sweeping victory hastened the demand for independence coupled with the suggestion that the grant of it would end Malaya's war with the Communists, which had started in 1948 with an armed Communist revolt. Operating from jungle camps, about 4,000 Chinese Communists, former guerrillas from the Japanese War, together with schoolboys and criminals, attacked lonely police stations and the bungalows of European planters and miners, slashing rubber trees and stealing latex for their own support. Though they failed to paralyze commerce or establish Communist areas, they murdered informers and forced Chinese squatters near the jungle to give them food. To deprive the terrorists of food, more than 550 new villages were built for the Chinese squatters and surrounded by barbed wire, the transport of rice was controlled, and the food supplies of villages that helped the bandits were rationed.

In 1951 the high commissioner, Sir Henry Gurney, was murdered by the terrorists, and Gen. Sir Gerald Templer succeeded with military as well as civil powers. He employed to the full the measures available to him. A federal volunteer regiment was created, and when 81% of the volunteers proved to be Malays a new law was introduced making two years' service compulsory for young men of all races. Leaflets promised immunity to Communist guerrillas who surrendered. Villages that helped the bandits were fined and the inhabitants confined to their houses by curfew. Helicopters were used to surprise jungle camps. The worst was over by 1954 and Templer left Malaya, but the small hard core of terrorists continued to give trouble.

On Aug. 31, 1957, the nine Malay states, together with the British settlements of Penang and Malacca, were granted independence. On that date Queen Elizabeth II ceased to be sovereign of Penang and Malacca and ceased to have jurisdiction over the protected Malay states, though the new Federation of Malaya decided to remain within the Commonwealth of Nations and Great Britain guaranteed its external defense and continued to provide troops. The federation had a head of state elected by and from the Malay rulers every five years. The first chosen was the ruler of Negri Sembilan, a namesake but no relation of Tunku Abdul Rahman (q.v.), leader of the Alliance Party that won independence and first prime minister of the new Malaya. The state of emergency

(declared June 16-19, 1948) was ended July 31, 1960. In July 1961 Malaya joined with Thailand and the Philippines in the establishment of the Association of Southeast Asia (ASA), the purpose of which was to bring about closer economic and cultural grouping.

For events immediately preceding and following the creation of Malaysia, see below, *Malaysia*. (R. O. Wt.)

B. SABAH

The connections of Sabah (called North Borneo during the British period) in the past were largely with the Philippines to the north, and they included many movements of men and ideas to and fro during thousands of years. The first Portuguese and Spaniards reached Borneo in the 16th century, but it was not until the Scottish voyager Alexander Dalrymple (q.v.) sailed the Sulu Sea in 1759 that western contacts reached large proportions. The East India Company settled Balambangan Island, off the northern tip of Borneo, in 1773, abandoned it in 1775, reopened it in 1803, and finally gave up in 1805 (14 years before Sir Thomas Stamford Raffles raised the British flag on Singapore).

The British occupied Labuan as a crown colony in 1846 but did not return to the mainland until 1877, when a private syndicate (later to become the British North Borneo Company) obtained grants of land from the sultans of Brunei and Sulu, hitherto unchallenged sovereigns in the north. Among those associated with the group was Adm. Sir Henry Keppel, intimate and ally of Sir James Brooke in Sarawak (see below) 40 years before. After some initial competition from the Sarawak administration, the company, under royal charter, reigned unchallenged from 1882. There had been intertribal feuding and local piracy. By a series of further land grants from the Brunei nobility Sabah acquired its final shape in 1898, although in 1948 some small "turtle islands" to the north were handed back to the Philippine government, in settlement of an old claim that the Sulu sultanate had acted out of order by ceding them.

In 1899 opposition to the company's rule flared into revolt, led by a Muslim Bajau, Mat Salleh. It required Borneo's first major paramilitary operation finally to destroy his forces in a long and bloody siege of his last-stand fortress (with stone walls 8 ft. thick) near Ranau, in the shadow of Mt. Kinabalu, early in 1900. Mat Salleh's followers continued to resist and made one serious raid on the hamlet of Kudat.

During the first half of the 20th century extensive rubber plantations and smaller coconut plantations were developed with European capital, followed by tobacco (at Lahad Datu) and timber extraction. During World War II the Japanese forcibly took over all of Borneo in 1941-42. During the next four years administration, social services, and business organizations came nearly to a standstill. A second paramilitary operation liberated the area. This was completed when the Australian 9th Division landed on Labuan and near Beaufort in June 1945. After a year of military administration, crown colony status was granted to the area and the island of Labuan (previously administered from Malaya) was incorporated as an integral part. In September 1963 Sabah joined the Malaysia federation. For subsequent events see below, *Malaysia*. (T. Hn.)

C. SARAWAK

Archaeological excavations at the Niah caves 40 mi. (64 km.) S of Miri indicate that this site may have been under human occupation for more than 50,000 years. Archaeological and related work also shows that small-scale barter prior to the 6th century A.D. in Borneo grew to large-scale traffic with both China and Siam by the 12th and 13th centuries A.D., continuing into the 14th century. Both the Sri Vijaya empire, centred in Sumatra until the 13th century, and Majapahit, its Javanese successor in the 14th and 15th centuries, exerted a strong influence on Sarawak. Majapahit fell to the Muslim states in the 15th century, and Sarawak became the southern province of the sultanate of Brunei.

The history of Sarawak as a state begins in 1839, when the Malays and Land Dayaks were in revolt against the sultan of

Brunei. The sultan had sent his uncle, Raja Muda Hassim, to pacify the country. In 1840 the latter requested an Englishman, James (later Sir James) Brooke (q.v.), to assist him in restoring order. Brooke did so and was rewarded in 1841 by being installed as raja over the territory from Tanjong Datu (Tanjong, "cape") to the Samarahan River. For the next 23 years Brooke devoted himself to the suppression of piracy and headhunting. In 1850 Sarawak was recognized as a separate state by the United States, and in 1864 Great Britain recognized its independence. From 1861 until 1905 the original territory continued to grow through cession, annexation at the request of its inhabitants, and purchase.

In 1868 Brooke died and was succeeded as raja by his nephew, Charles Brooke. The latter ruled until 1917 when he was succeeded by his son, Charles (later Sir Charles) Vyner Brooke. In 1941 Brooke abrogated his absolute powers by enacting a new constitution designed to establish democratic self-government for Sarawak. This initial effort was nullified by the invasion of Borneo by Japanese forces in 1942. The Japanese occupation, which lasted three and a half years, brought disruption, misery and ruin. In 1946, after studying the devastation, the raja and his council voted to cede the country to the British crown, and the cession was accepted the same year.

While a British colony, Sarawak moved steadily toward self-government and the creation of a representative legislature. This goal was achieved in June 1963. In September 1963 Sarawak joined in the formation of Malaysia. For subsequent events see below, *Malaysia*. (S. L. Sz.)

D. MALAYSIA

Malaysia, a federation of the states of independent Malaya, self-governing Singapore (which seceded in 1965), and the former British colonies of Sarawak and Sabah (North Borneo), came into existence on Sept. 16, 1963, in the face of Indonesian hostility and the disapproval of the Philippines, which had laid claim to Sabah. The first head of state was the ruler of Perlis, the first prime minister Tunku Abdul Rahman.

Discussion and negotiations for the formation of Malaysia had begun in 1961, after Tunku Abdul Rahman, then Malaya's prime minister, suggested that by creating a federation that would include the Borneo territories the political separation of Singapore from Malaya could be ended without upsetting the balance between the two racial groups, the Malays and the Chinese. The fusion of Malaya with Singapore, the peninsula's greatest port, was clearly economically advantageous. A joint working party and community leaders prepared the ground.

The Singapore electorate approved, by a referendum, the basic principles of federation as far as Singapore was concerned. A commission of British and Malayan representatives tested opinion in Sarawak and Sabah and unanimously recommended federation subject to safeguards. Agreement on the establishment of Malaysia was then signed in London in July 1963. Brunei, the third state in "British" Borneo, whose adherence to the federation had been envisaged, decided not to join. The Malayan government, to meet the opposition of its neighbours, agreed that the secretary general of the United Nations should be invited to ascertain the wishes of the people of Sarawak and Sabah; an assessment in favour of federation was made by a team of UN officials.

Indonesia and the Philippines rejected the UN findings and withdrew their diplomatic missions from Kuala Lumpur when Malaysia was established. Indonesia attempted to undermine the new state by military, economic, and diplomatic pressure. Indonesian commandos carried out armed incursions in Sarawak and Sabah and seaborne and airborne landings in West Malaysia. There were also attempts at subversion, bomb outrages, and other acts of sabotage. British and Commonwealth units took an active part in the military operations. After the October 1965 coup in Indonesia (q.v.) and the later change of government, however, Malaysian and Indonesian representatives reached agreement in Bangkok in June 1966 on the ending of the "crush Malaysia" campaign.

Meanwhile friction between Singapore and the central govern-

STATE SECRETARIAT IN KUALA LUMPUR

ment had led in August 1965, at the central government's initiative, to Singapore's leaving Malaysia and becoming independent.

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Federal Government.—Malaysia is a monarchy, the sovereign (with the title *yang di-pertuan agong*, "supreme head of the federation") being elected for a five-year period from among, and by, the hereditary rulers of the nine Malay states. The governors of the other four states, which were British colonies or settlements, are members of the Conference of Rulers, which has limited constitutional duties. The Alliance Party (composed of the United Malays National Organization, the Malayan Chinese Association, and the Malayan Indian Congress) came to power in Malaya in 1958 and in Malaysia in 1963. In Sarawak and Sabah the branch Alliance parties in each case have somewhat different constitutional organizations. They formed the first state governments in the federation.

The federal Parliament (*Majlis*) is bicameral. The House of Representatives (*Dewan Ra'ayat*) is elected for five years. The Senate (*Dewan Negara*), with a life of six years, is partly appointed and partly elected by the legislatures of the 13 states, each of which has two senators. West Malaysia elects 104 members of the House of Representatives. The 24 members for Sarawak and the 16 members for Sabah are elected by the state assemblies; the first direct elections in East Malaysia were scheduled to take place in 1967.

Judicial authority is vested in the separate High Courts of West and East Malaysia, with subordinate courts in the chief centres of population. The very large majority of cases, criminal and civil, are disposed of by sessions and magistrates' courts. Final appeal is to the Privy Council in London, which tenders advice to the crown. In capital cases trial is by jury, and the accused receives free legal aid. In West Malaysia there are also Islamic religious courts, the jurisdiction of which includes matrimonial affairs. Islam is the official religion, religious affairs being the responsibility of state governments. There is freedom of worship for all faiths.

2. State and Local Government.—Each state has an elected Legislative Assembly and an Executive Council on parliamentary lines with a chief minister. State responsibilities include the development of natural resources (notably the control of the utilization of land and mining), local government, and town and country planning. In practice there has been little conflict of interest with the federal government. The states have limited financial resources and receive annual grants from the centre. At local government level there are elected municipalities, town councils, town boards, and still smaller councils. The larger bodies are financially autonomous. The rural areas are controlled by district officers. In 1966 the entire system of local government was under investigation, and elections had been temporarily suspended. Kuala

Lumpur, the federal capital, is administered by a commissioner, responsible to Parliament. In Sarawak there are 23 district councils and, in Kuching, a municipal governing body. Sabah has town boards and district councils.

3. West Malaysia: Living Conditions.—A program of rural development improved general conditions throughout West Malaysia from 1955 onward, providing better health services, water and electricity supplies, access roads, bridges, and schools. The average standard of living is rated the third highest in Asia. Custom and lack of dietary knowledge rather than poverty are responsible for some malnutrition in rural areas. Such endemic diseases as tuberculosis, malaria, and yaws are being brought under control by government medical services including traveling dispensaries, but there is a shortage of doctors, in both government and private practice. More than a thousand rural health centres embrace the entire range of medical work. Women workers are given by law maternity leave and money grants, and workmen or their dependents receive compensation for accidents. A compulsory provident fund, realizable on retirement at 55, has more than 1,250,000 beneficiaries. Additional funds for social welfare are provided by a national lottery, drawn every three weeks. The 300 labour unions are nonpolitical and have a membership of 325,000. Many of the unions are small, but the National Union of Plantation Workers has more than 100,000 members. In the towns squatters are a hindrance to low-cost housing developments. The squatter population of Kuala Lumpur has been officially estimated at 100,000, about one in four of the population.

4. East Malaysia: Living Conditions.—In general the standard of living, public utilities, and social services are lower in East than in West Malaysia. All Sabah's main towns had to be rebuilt after the Japanese occupation. There is less urban development, the population density in both Sabah and Sarawak being little more than 17 per square mile. The scattered population makes the provision of state-wide education and medical services difficult. Each state has only 50 to 60 doctors. Sarawak has 10 hospitals, more than 50 static and traveling dispensaries, and 70 maternity and child welfare centres. Sabah has nine hospitals and 50 dispensaries and maternity and child health centres. Malaysian development planning provides for substantial advances.

5. Education.—One-fifth of the Malaysian budget is devoted to education, and one-fifth of the population attends school. Six years of free primary school is provided for every child, with a further three years of comprehensive education. Attendance is voluntary. A Malaysian outlook is being fostered by means of a common syllabus and system of examinations. All schools teach Malay, the national language, although more than half the primary pupils attend schools in which the medium of instruction is English, Chinese, or Tamil. Half a million children attend English-language schools.

West Malaysia has more than 1,322,000 children in primary schools and more than 480,000 in secondary and 8,000 in vocational schools; there are 25 institutions of higher education (including

*West Malaysia, 1957; East Malaysia, 1960.

teacher-training colleges), with about 8,000 students. The University of Malaya has faculties of arts, science, engineering, agriculture, medicine, and education, and a teaching hospital was under construction in the 1960s. Higher education is also provided by technical and teacher-training colleges. Sabah has about 100,000 children in primary schools and around 7,000 in secondary; comparable figures for Sarawak are 150,000 and 30,000. East Malaysia has a few teacher-training colleges, but higher education must be sought abroad and in West Malaysia.

The national language is assuming increased importance in all education and daily life. In 1967 Malay became the only official language, except in East Malaysia, where English was retained under the constitution.

6. The Indigenous People.—To improve the economic position of the rural Malays a Rural Industrial and Development Authority was set up in Malaya in 1954, reorganized in 1965 as the *Majlis Amanah Ra'ayat*, a council of trust for the indigenous people. Its activities have been extended to East Malaysia. An Agricultural Marketing Board was established in 1966. A national land authority is intended to prevent the further fragmentation of agricultural holdings caused by inheritance customs, and to consolidate uneconomic farms. The officially sponsored Bank Bumiputra, its capital subscribed by the federal and state governments and indigenous investors, helps to finance rural enterprise. Another corporation will promote the interest of the indigenous communities in forestry and mining. There is constitutional provision for advancement of the indigenous people. The federation's 3,500 cooperative societies have a membership of 500,000.

7. Defense.—Malaysia has a separate Army, Navy, and Air Force, with a total of 30,000 men. Each is supported by territorial organizations or volunteer reservists in addition to the normal reserve. The army included 12 infantry battalions in the latter 1960s (to be increased to 20), two reconnaissance regiments which have armoured units, two artillery regiments, an engineer corps, a signal corps, and transport services. The Navy, with a strength of 2,100 men, has one frigate, coastal and inshore minesweepers, and a number of fast patrol boats. The Air Force is equipped with fast troop and freight transport planes, helicopters, and jet trainers, and plans were under way for a small strike force. There is a flying school at Alor Star. The Federation Military College is at Port Dickson. British and Commonwealth strategic forces are based in Malaysia and Singapore under the Anglo-Malaysian Defense Treaty, extended to include independent Singapore. A paramilitary field force is attached to the police.

VI. THE ECONOMY

Three-quarters of Malaysia is covered with tropical rain forest. The economy is largely agricultural, distinguished by cash crops, mainly rubber, timber, palm oil, copra, and coconut oil. West Malaysia grows about 70% of its rice, East Malaysia about 50%. Tin and iron are the only important minerals, and their production is confined to West Malaysia.

1. West Malaysia: Production.—*Rubber.*—Rubber is produced on about two-thirds of the 6,500,000 ac. (2,600,000 ha.) under cultivation in West Malaysia, and the rubber industry, despite the competition of synthetic rubbers after 1945, is the mainstay of the Malaysian economy. West Malaysia produces more than one-third of the world's natural rubber. In the late 1960s production was over 1,000,000 tons per year, an increase of 250,000 tons since the beginning of the decade. Output continued to rise rapidly as more high-yielding trees came into production. Larger yield is a major factor in reducing production costs, a matter of increasing importance as natural rubber loses the price premium it commanded until the development of synthetic rubbers which approach more closely the special properties of natural rubber. All the rubber trees of Southeast Asia are the descendants of seedlings germinated in Kew Gardens in London, at the end of the 19th century, but they are as different from the original Brazilian jungle tree (*Hevea brasiliensis*) as the racehorse is from the Arab stallions which were the Thoroughbred foundation stock. Selective breeding by artificial pollination of the best-yielding trees has produced

clones, or families, which yield four and five times as much rubber as the first plantation trees did. In the 1960s the average yield an acre was nearly 900 lb. (400 kg.), as compared with 500 lb. in 1956; many plantations averaged 1,200 lb., and sections of these estates recorded much higher figures. The leading clones yielded more than 2,000 lb. (900 kg.), and one experimental clone in its eighth year of tapping produced just short of 4,000 lb. an acre. Trials extending over 12 years are necessary before new clones can be recommended even for limited commercial planting.

More than 4,000,000 ac. (1,618,700 ha.) are under rubber in West Malaysia. More than half of this acreage belongs to smallholders owning from 3 to 100 ac. each, who produce 45% of the rubber. Of large estates up to 14,000 ac. (5,665 ha.) in area 60% are European-owned; local investment in these companies has increased, however, and a number of large estates have been sold and broken down into small holdings. Chinese and Indian estates have equally high production standards. About 300,000 workers are employed on the plantations, mainly Indians and Chinese. Replanting with high-yielding trees is financed through a tax on rubber exports. The special scheme for smallholders provides annual payments while the trees are maturing, payment being dependent on an approved standard of cultivation.

The Rubber Research Institute's scientists, who developed the modern rubber tree, are improving the processing of the latex and helping to modernize the marketing of what has ceased to be a simple agricultural crop. For over 60 years rubber was sold in smoked sheets on the basis of colour and appearance (such as lack of air bubbles), which were no indication whatever of quality. A new manufacturing process produces crumbled, or granulated, rubber of standard types with uniform physical qualities, suitably packaged, and much more easily compounded by tire-makers and other manufacturers. The old-fashioned, cumbersome bale of rubber is expected to disappear. Special-quality natural rubbers are also being produced, and important consequences may follow study of the factors which control the process by which rubber is synthesized in the tree. The general principles of this have only recently been understood.

Other Crops, and Fisheries.—Higher-yielding varieties of rice together with irrigation, double cropping, and better farming techniques were largely responsible for the increase in rice production from 350,000 to 570,000 tons milled during the decade 1956-66. In the same period the yield rose from 1,000 lb. (450 kg.) an acre to 1,500 lb. An entirely new variety developed in the Philippines is expected to raise this figure substantially. Despite the high annual rainfall, irrigation is necessary in many parts of West Malaysia because of the high runoff.

Production of coconut oil and of copra cake, which fell to 64,000 tons and 40,000 tons in 1965, began to recover with the replanting of estates and small holdings. Coconuts are also a major food item. Tapioca, sweet potatoes, sago, tobacco, and sugarcane are minor crops, and 223,000 ac. (101,000 ha.) are planted in mixed fruit trees, chiefly durian, mangosteen, and rambutan in small holdings. There is no specialized fruit-growing, except pineapples for canning and a small acreage of citrus fruits. Vegetables for local consumption are produced everywhere by Chinese market gardeners. Production of palm oil has been increasing rapidly to 150,000 tons. Smallholders are being encouraged to switch to some extent from rubber, and many large rubber estates are diversifying with oil palms.

Livestock is raised only on a small scale. Malay farmers keep buffaloes and other cattle as draft animals and for meat. Dairy cattle are kept mainly by Indians. The Chinese produce about 30,000 tons of pork yearly, two-thirds of all the locally produced meat. From the poultry farms every year come 500,000,000 eggs and 45,000 tons of chicken.

About 200,000 tons of fish are landed annually, caught mostly in coastal waters, though deep-sea fishing is increasing; another 25,000 tons comes from fresh-water fisheries, including fish ponds and the paddy fields.

West Malaysian forests produce every year about 1,100,000 tons of timber, of which nearly two-thirds is exported.

Mining.—Tin is second to rubber in Malaysia's export economy.

BY COURTESY OF BRITISH INFORMATION SERVICES

WASHING CASSITERITE, TIN ORE, AT AN OPEN-PIT MINE ON THE WEST COAST OF MALAYA. THE ORE IS SMELTED AT PENANG AND SINGAPORE

and it has a much longer history in the peninsula. Tin was mined in West Malaysia before the Portuguese arrived in Malacca, and in the 17th century the Dutch established trading stations for collecting tin mined by the Chinese in Perak. In the 1850s the Chinese began working new tin fields in Perak and Selangor, enterprises which led to clan wars for possession of the mines and thus to British intervention in the 1870s. During 1885-1965 West Malaysia was the world's biggest tin producer, mining 60,000 tons a year, about 40% of the world supply. Most of this was produced by gravel pumping or dredging. In gravel pumping the tin-bearing ground is broken by jets of water under high pressure and the debris pumped up to a concentration point. Dredging, introduced in 1912, is of European origin. A modern dredge can dig to 150 ft. (46 m.) in swampy ground, and attention is being given to the offshore dredging of alluvial deposits which contain cassiterite. Variants of the gravel-pump method are used in other forms of open-cast mining, and there is a little lode-mining. Up to 2,000 tons a year is produced by dulang washers, mostly Chinese women, who pan the cassiterite as though it were gold. The tin is smelted in Penang.

Iron mining was of no significance until the Japanese acquired concessions on the east coast in the 1930s. The mines are no longer Japanese, but the ore is shipped to Japan. Production was trebled between 1956 and 1966, to a peak of over 7,000,000 tons. Bauxite is mined in south Johore; production averages between 400,000 and 800,000 tons a year, all of it exported, mainly to Japan. Ilmenite, columbite, monazite, and zircon, by-products of tin mining, are all recovered in small amounts and are also exported. A small quantity of kaolin (China clay) is used locally. Coal and gold are no longer mined.

2. East Malaysia: Production.—Rubber, rice, and coconuts are the principal agricultural crops in Sarawak and Sabah, but timber is the major export of both states. Sabah has about 24,000 sq. mi. (62,160 sq. km.) of forest, 80% of the land area; Sarawak has 35,000 sq. mi. (90,649 sq. km.), only a slightly smaller proportion. The forests are commercially exploited on an 80-year rotation plan. The value of Sarawak's timber exports rose after 1945 from practically nothing to more than one-third of the state's export total. Sarawak exports about 45,000 tons of rubber each

year, Sabah 23,000 tons. The cultivation of oil palms is being encouraged in Sabah, and hemp and cocoa are grown. Pepper and sago are other important Sarawak crops. Neither state produces more than half its rice needs. Bauxite is no longer mined in Sarawak, and it is doubtful whether there are any minerals of economic importance in either state, with the possible exception of copper. Sarawak has a little petroleum from the wells at Miri, on the coast, but Miri's real importance lies in the small refinery at Lutong, immediately to the north, and in its shipping facilities for Brunei oil from the fields at Seria, only about 30 mi. (48 km.) away. Both Sarawak and Sabah have had a shortage of skilled labour, and immigration from West Malaysia is being encouraged. The indigenous people have in the main a subsistence economy. East Malaysia has been brought into the Malaysian customs area, and taxation, including income tax, is being adjusted to federal rates.

3. Trade and Finance.—Malaysia and Singapore have a common banking system and until June 1967 had a common currency. The Malaysian dollar has a gold value of 0.290229 grams (Mal. \$1 = 34 cents U.S. = 2s. 4d. sterling); the Malaysian dollar is not linked to sterling. (Where figures are given in dollars below, the reference is to Malaysian, not U.S., dollars.) The Bank Negara is the currency-issuing authority. The country has 33 commercial banks, 13 of which are incorporated in Malaysia.

Budgetary expenditure, which in 1966 was \$1,600,000,000 in the ordinary account, is rising by 10% annually. Development expenditure was estimated in 1966 at \$600,000,000. The government's public debt is equal to about 30% of the gross national product. The main sources of revenue have been the customs duties, export duties on tin and rubber, and income tax.

Normally Malaysia has had a substantial favourable annual trade balance of between \$250,000,000 and \$570,000,000, but not necessarily a surplus balance of payments. There has usually been a large deficit on services and transfers, including the profits of overseas companies which have been remitted abroad. Nearly one-third of Malaysia's foreign trade passes through Singapore. The United States, Japan, the United Kingdom, and the U.S.S.R. have been Malaysia's principal customers, and the United Kingdom and Japan the largest suppliers.

Of Malaysian imports, food, beverages, and tobacco represent about one-quarter, manufactured goods about one-quarter, and machinery and equipment just under one-quarter. Mineral fuels, inedible crude materials, and chemicals account for most of the rest.

In the period 1960-65 Malaysia's exports increased 6%, in 1965 totaling \$3,786,000,000, of which rubber, tin, timber, iron ore, and palm oil accounted for 80%. Exports are subject to the serious fluctuations of commodity prices, and a fall of one cent in the price of rubber represents a fall of \$22,000,000 in the country's annual export earnings. In 1960-61 the average price of rubber fell by 24½ cents a pound, and in 1966 it was less than 70 cents. Tin rose from an average of £797 (U.S. \$2,232) a ton in the London metal market in 1960 to £1,413 (U.S. \$3,956) in 1965. The gap between world production and demand was met by releases from the U.S. tin stockpile surplus. As the gap closed, the price fell again near to the levels at which the International Tin Council Price Control Scheme would operate.

The first Malaysian Development Plan, 1966-70, an integrated program for all the territories, called for development expenditure of \$4,550,000,000 in the public sector, of which one quarter would be for agricultural and rural development, and of \$5,950,000,000 in private investment. The manufacturing sector accounted for only 10% of the gross domestic product and for 6% of total employment, but efforts were being made to increase these figures. Pioneer industry, for which overseas capital was welcomed on a joint venture basis, was encouraged by exemption from income tax for two to five years and by protective tariffs. The largest of the industrial estates was at Petaling Jaya, a satellite town a few miles from the capital.

4. Transport and Communications.—*West Malaysia.*—Until the 1880s rivers were virtually the only means of transport in West Malaysia, but they are now of no significance. The first roads outside Penang Island were built to give access to the tin fields, and 16 mi. of railway were built in the Kinta Valley, in

Perak in 1893, for the same reason. The railways opened the way for economic development, and roads followed when rubber growing began. Railways built by the west coast states were amalgamated in 1901, and in 1923 a granite causeway was built across the Johore Straits, linking Singapore with the Malaysian railway up to the Thai border, 488 mi. (785 km.) N. There are now 1,321 mi. (2,125 km.) of largely single-track railway. The main line runs near the west coast with spur lines to Port Swettenham, Port Dickson, and Port Weld. There is an international train service from Kuala Lumpur to Bangkok. From Gemas, south of Kuala Lumpur, a branch line runs across the central mountain chain north to Kota Bharu, an alternative route to Thailand. The railway has been carrying 6,000,000 passengers a year and nearly 4,000,000 tons of freight. Steam traction has given way to diesel locomotion.

West Malaysia has 2,718 mi. (4,374 km.) of federal roads and 6,093 mi. (9,805 km.) of state roads, excluding municipal roads. Most of this network is on the west coast. There is one motor vehicle to every 20 persons, of which a third are private cars. Malaysia has the densest road traffic of any Asian country, with the exception of Japan and Singapore. The 700 bus routes carry more than 325,000,000 passengers a year. Commercial vehicles are up to 20 tons capacity, and they carry more freight than the railways.

Malaysia-Singapore Airlines operates the domestic air services, and flights to Singapore carry more than 600,000 passengers a year. Overseas routes are flown by jet liners to East Malaysia, Brunei, Thailand, Hong Kong, Japan, Indonesia, and the Philippines. The Kuala Lumpur Airport at Subang is built to the highest international standards, with a main runway of 11,400 ft. (3,475 m.).

There are two ocean ports on the west coast, Penang, which handled 3,312,000 tons of freight in 1965, and Port Swettenham, 2,706,000 tons. A number of minor ports along the 1,200-mi. (1,930-km.) coastline are used by fishing vessels and small coastal trading craft. Malacca is among the more important of them. Of the 10,000,000 tons of goods which have been passing through the minor ports every year, more than half is accounted for by iron ore, shipped mainly from Kuala Dungun, on the east coast.

The telephone service has more than 100,000 subscribers, nearly all connected by automatic exchanges through which they can dial any part of the country. A high-capacity microwave system is used. Calls can be made, and a telex service is also available, to most parts of the world. Radio Malaysia, a government department, operates the broadcasting and television services. An estimated 800,000 households have radios, and in 1965 there were 50,000 television licence holders. Both services are supported by commercial advertising. Malaysia's postal services handle more than 300,000,000 articles a year.

Daily newspapers in Malay, English, Chinese, and Tamil, published in Kuala Lumpur, are on sale by early morning in all parts of the country. Penang is a smaller publication centre. Most of the larger papers have combined Malaysian and Singapore circulation, the biggest daily circulation, that of an English-language paper, being more than 150,000 (200,000 on Sunday). A national news agency, the services of which all newspapers share, was to begin operation in 1967.

East Malaysia.—Rivers are still the principal means of inter-

nal communication in Sarawak. All flow into the South China Sea from the watershed which is roughly the border with Indonesia. From the ports of Kuching, Miri, and the Rejang River there are passenger and cargo services overseas. There are 565 mi. (908 km.) of road, improved and added to by military requirements during the periods of Indonesian threat. Sibuan and Miri have small road networks, and there is a coast road from Miri to Brunei.

In Sabah the rivers are not much used. The state has 1,400 mi. (2,250 km.) of road, a fifth of them metalled, serving the settled areas. From Jesselton 100 mi. (160 km.) of single-track high railway runs to Weston and Melalap. The chief Sabah ports are Sandakan, Jesselton, Tawau, Kudat, and Victoria, a duty-free port on the island of Labuan in Brunei Bay.

Six East Malaysian airfields with full traffic control services, and ten lesser public airports, are all served by Malaysia-Singapore Airlines. Aircraft, as of the mid-1960s, were the only cross-country means of communication. Local newspapers are published in both states, and West Malaysian papers arrive each morning by air mail. Radio Malaysia operates the broadcasting services, which include programs in local languages.

MALBONE, EDWARD GREENE (1777-1807), U.S. artist generally regarded as the greatest of American miniaturists, was born at Newport, R.I., in August 1777. Largely self-taught, he began his professional career in Providence, R.I., at seventeen and quickly developed a remarkably fine technique. A man of agreeable manners, diligent, and blessed with what Washington Allston called "the happy talent . . . of elevating the character without impairing the likeness," Malbone was during his short career the most sought-after miniaturist of his day in Providence, Newport, Boston, New York City, Philadelphia, and Savannah. His career was cut short by tuberculosis, of which he died at Savannah, Ga., on May 7, 1807. Many of his miniatures have survived and are highly prized for their delicacy of drawing, richness of colour, and convincing characterization. He had no formal pupils, but freely advised other artists, notably Charles Fraser, William Dunlap, and John Wesley Jarvis.

See Ruel P. Tolman, *Life and Works of Edward Greene Malbone* (1957). (D. H. W.)

MALBORK (Ger. *MARIENBURG*), a town in northern Poland, in Gdansk wojewodztwo (province), lies on the right bank of the Nogat river—one of the three mouths of the Vistula, 25 mi. S.E. of Danzig. Pop. (1960) 25,260. It is located on the border of the Zulawy plains and the Masurian lakes. Malbork is a junction for the Warsaw-Danzig, Torun-Braniewo and Olsztyn-Danzig railway lines, and for a number of roads connecting the highlands with the Zulawy region. The town developed on the trade route along the Nogat river from north to south.

Malbork grew up around the castle, founded c. 1274 by the Teutonic Order, and the settlement was given town rights in 1276. From 1309 to 1457 it was the seat of the grand master. During the Thirty Years' War the Poles occupied the town (1457), which was included in Poland after the Torun (Thorn) peace treaty of 1466. After the first partition of Poland in 1772, Malbork passed to Prussia. It was retained by Germany in the plebiscite of 1920 and was returned to Poland in 1945.

The huge castle, rebuilt in the 14th and 19th centuries, was badly damaged during World War II. Partly reconstructed by the 1960s, it bears witness to the wealth and military power of the Teutonic Knights. It consisted of three lines of defense: the *przedzamcze* (forecastle) surrounded by a large outer moat, the middle castle and the high castle.

Local agriculture provides raw materials for the Malbork sugar factory, flax works and dairies. (K. M. Wl.)

MALCOLM, the name of four Scottish kings.

MALCOLM I (d. 954), king from 943 to 954. He received Strathclyde from the Anglo-Saxon king Edmund I in 945, promising in return to support Edmund by sea and land.

MALCOLM II (c. 954-1034), king from 1005 to 1034, was a grandson of Malcolm I. He invaded northern England several times and by the battle of Carham (1016 or 1018) finally secured Lothian for Scotland. He died at Glamis on Nov. 25, 1034.

MALCOLM III Canmore (c. 1031-1093), king from 1058 to 1093, was great-grandson of Malcolm II. He succeeded to the throne after defeating Macbeth near Lumphanan in Mar, having spent several years of his youth in exile at the court of Edward the Confessor. After the Norman conquest he gave shelter in Scotland in 1068 to Edgar the Aetheling and his sisters, one of whom, Margaret, became his second wife soon afterward. He did homage to William I at Abernethy in 1072, giving his eldest

son, Duncan (afterward Duncan II), as a hostage and receiving lands in England. His frequent raids into England caused castles to be built at Carlisle and Newcastle-upon-Tyne.

A visit to William II at Gloucester in 1093 did nothing to improve their relations, and later that year Malcolm again invaded England, reaching Alnwick, where he was killed with Edward, his eldest son by Margaret. On his death a Celtic reaction brought his brother Donaldbane, to the throne. Of his six sons by Margaret, three succeeded to the throne in turn—Edgar, Alexander I and David I. Of his two daughters, Matilda married Henry I of England, and Mary married Eustace III, count of Boulogne.

MALCOLM IV (1142-1165), king from 1153 to 1165, was the eldest son of Henry, earl of Huntingdon, and grandson of David I, whom he succeeded. By a treaty made at Chester with Henry II of England in 1157, the boundary of the kingdoms was fixed at the Tweed and the Solway. He was knighted by Henry II during the Toulouse campaign of 1159. He died at Jedburgh on Dec. 9, 1165.

MALDA, a town and district in the Presidency division of West Bengal, India. The town (pop. [1961] 4,885), sometimes called Old Malda, lies on the left bank of the Mahananda river near its confluence with the Kalindri (the main stream of the Ganges). It was the port of Pandua and had a large entrepôt trade in cotton and silk fabrics in the 18th century when the Dutch, French and English built factories there, and it still functions as a distributing centre of rice and jute grown in north Bengal. The Jumma Masjid is an important mosque, and across the river is the tower of Nimasarai, a landmark of the neighbourhood.

MALDA DISTRICT covers an area of 1,436 sq.mi. Pop. (1961) 1,221,923. The Mahananda river divides it into two distinctive regions, the eastern being designated as the Barindra, and the western, the Rarh. The Barindra forms a part of the older Ganges delta and is characterized by rolling plains and low hills. Low-lying flat alluvial plains characterize the Rarh region, the northern part of which is marshy. On the south of the Kalindri river lies the most fertile and densely populated part of the district. Rice, jute, pulses and oilseeds are the principal crops. Mulberry plantations and mango orchards occupy considerable areas in the central and southern parts; and the district's economy depends mainly on the mango trade and silk manufacture.

English Bazar or Angrezabad (pop. [1961] 45,900), founded by the British in 1770, is the headquarters of the district. It has a large trade in silk, jute and mangoes. The ruined city of Gaur (*q.v.*), an ancient capital of Bengal, lies 10 mi. S.W. of English Bazar, and about 20 mi. away (6 mi. N.E. of Malda) are the ruins of Pandua. This city succeeded Gaur as capital of western Bengal about 1340, but in 1455 Gaur resumed its former status and Pandua declined. The 14th-century Adina mosque and the Sona or Golden mosque are conserved by the government. (S. P. C.)

MALDEN, a city in Middlesex county, Mass., U.S., on the Malden river, a branch of the Mystic river, 5 mi. N. of Boston. Pop. (1960) 57,676. It is almost surrounded by Melrose, Revere, Everett and Medford (*qq.v.*), with the Middlesex Fells (a state reservation) forming its northwest boundary.

When first settled, mainly by Puritans, on the north side of the Mystic river, Malden was part of Charlestown (*q.v.*) and was known as the Mystic Side. It was incorporated as the town of Mauldon (for Malden, Eng., the home of some of the early settlers) in 1649 and was chartered as a city in 1881. Its bicameral council was abolished in 1958 in favour of a single chamber council. Of historic interest is Bell Rock Memorial park, named for the bell which in colonial times summoned the people to worship or sounded alarms in times of danger, with a Civil War Soldiers and Sailors monument at its summit.

Malden is a residential community with some industrial development and is also an important suburban Boston shopping centre. Manufactures include rubber footwear, electronic and radio parts, aircraft engine parts, metal cans, paints, drugs, knitted clothing and foods. (L. G. H.)

MALDIVE ISLANDS, an independent sultanate in the Indian Ocean, consists of a chain of about 2,000 low-lying coral islands grouped in a number of clusters or atolls situated between latitudes 7° 6' N and 0° 42' S, about 400 mi. (645 km.) SW of Ceylon. Area c. 115 sq.mi. (298 sq.km.). One and Half Degree Channel separates the main chain of atolls from Suvadiva, which is again separated from the southernmost atolls of Addu and Fua Mulaku by the Equatorial Channel. The climate is hot and humid and malaria prevails.

Only about 220 islands are inhabited and the total population (1965) was 97,743. The capital island is Male (pop. [1965] 11,202). The Maldivians are a mixed people; probably of Aryan stock, speaking a language akin to Elu or old Sinhalese.

Islam was adopted in the islands in the 12th century and in the 14th century Ibn Batutah, the Arab traveler and historian, described the conditions there. The ruler was a sultan of the still existing ad-Din (Didi) dynasty. The Portuguese forcibly established themselves there from 1518 for about ten years. In the 17th century the islands came under the protection of the Dutch rulers of Ceylon. Protection was extended by the British when they took possession of Ceylon and was formally recorded in an agreement of 1887. In 1948, when Ceylon became independent, a new agreement provided that Britain should control the foreign affairs of the islands and not interfere internally. The sultan undertook to provide necessary facilities to British forces for the defense of the islands or the Commonwealth.

In December 1956 Britain made an agreement permitting re-establishment of a wartime airfield on Gan Island in Addu Atoll as a staging post between Britain and the Far East and Pacific and undertook resettlement of Gan islanders. A change of administration then took place and the new government asked for a review of the Gan and also of the 1953 agreement; negotiations were suspended in March 1959. About that time insurrection against the Maldivian government broke out in the southern atolls and a British dispatch of famine relief to the rebellious Suvadiva Atoll, 60 mi. (97 km.) N of Gan, led to charges of interference in internal affairs and the dispatch of Maldivian armed parties, resulting in violence and loss of life. In February 1960, however, the Maldivian government presented the British government with the use of Gan and other facilities in Addu Atoll for 30 years, with effect from December 1956, and in return received a direct grant of £100,000 and a grant of £750,000 to finance specific development projects over a period of years. The new agreement reaffirmed Britain's defense obligations, leaving the Maldivian government to conduct its own external cultural and economic affairs. By a new agreement of July 1965 Britain recognized the Maldive Islands as a completely sovereign and independent state, and ceased to be responsible for the defense of the islands. The agreement confirmed Britain's right to continue to use the facilities in Addu Atoll.

The Maldives have a *majlis* (parliament) to which all islands elect members. The atolls are covered with coconut palms, and millets and tropical fruit and vegetables are grown. The principal industry is fishing; "Maldive fish" prepared from bonito and tuna are the main exports. There is also coir and lace making. Most of the trade is with Ceylon.

See H. C. P. Bell, *History, Archaeology and Epigraphy of the Maldive Islands* (1940); T. W. Hockly, *The Two Thousand Isles: a Short Account of the People, History and Customs of the Maldive Archipelago* (1935).

MALDON, a market town, municipal borough and port of Essex, Eng., lies on the south side of the Blackwater estuary, 10 mi. E. of Chelmsford by road. Pop. (1961) 10,509. Finds of prehistoric objects indicate early settlement, and the Anglo-Saxon Chronicle relates that Edward the Elder established a "burg" there in 916.

In 991 it was the site of a battle fought by Brihtnoth, ealdorman of Essex, against Danish marauders who were victorious. The incident is commemorated in an Old English poem, *The Battle of Maldon*. It remained a royal town up to the reign of Henry I and thus is entered as being on *terra regis* in Domesday Book. Henry II granted the burgesses their first char-

ter in 1171. Of many later charters, that granted by James II (1686) vested the chief authority in a mayor. The present charter dates from 1810. All Saints church stands on top of the hill and has a unique 13th-century triangular tower; in the churchyard is buried Laurence Washington, great-great-grandfather of George Washington, who was rector of Purleigh, nearby, from 1633 to 1643. Maldon was probably the birthplace (c. 1727) of Horatio Gates, the American general. The moot hall, or d'Arcy tower was built in the reign of Henry VI and was presented to the town in 1440 by Sir Robert d'Arcy. The Plume library, left to the town by Thomas Plume, archdeacon of Rochester, at his death in 1704 contains rare books and manuscripts; he erected the present brick building to house it. The grammar school was founded in 1603. Maldon has many summer visitors and there is yachting on the Blackwater. There are foundries, timber and flour mills, an oyster fishery and some shipping.

Beeleigh abbey (1 mi. W.), a Premonstratensian foundation of c. 1180, is a 16th-century residence in which the chapter house and fragments of 13th- and 15th-century date are incorporated.

MALDONADO, a department on the Atlantic coast of Uruguay, is best known for Punta del Este, a fashionable ocean resort area, one of many that dot the long coast line of the department. Off the coast of Punta del Este is Isla de Lobos, a small, rocky island where sea lions congregate annually by the thousands. Hunting of these animals during these gatherings has resulted in a profitable trade in their skins.

Ranching and agriculture are the principal activities in the interior of Maldonado. Sheep and cattle are raised. Major crops include sugar beets, sunflower seeds, forage crops, and wheat.

The population of Maldonado was 61,548 in 1963. The capital Maldonado, was established in 1757 and first named San Fernando; its population (1962 est.) was 15,900. The area of the department is 1,587 sq.mi.

(M. L. V.)

MALEBRANCHE, NICOLAS (1638-1715), French Cartesian philosopher whose work was to complete René Descartes' dualistic doctrine of mind and matter in a way compatible with Catholic theology under Augustinian and Neoplatonic influences. He was born in Paris on Aug. 6, 1638, the youngest child of Nicolas Malebranche, secretary to Louis XIII, and of Catherine de La Zouche. He suffered all his life from malformation of the spine. At the age of 16 he entered the Collège de La Marche, but with the philosophy there, as with the theology later studied at the Sorbonne, he was profoundly dissatisfied. In 1660 he joined the Congregation of the Oratory, where Augustinian and Cartesian influences were then current.

A chance reading of Descartes's *De Homine* in 1664 determined Malebranche's vocation. The idea and application of "a universal mechanics" in that work fired his imagination, and "the joy of becoming acquainted with so many discoveries caused such palpitations of the heart that he was obliged to stop reading in order to recover his breath." From that moment Malebranche systematically studied mathematics, physics and the writings of Descartes, who, he declared, "had discovered in thirty years more truths than all other philosophers together."

The first two volumes of his principal work, *De la Recherche de la vérité, où l'on traite de la nature de l'esprit de l'homme et de l'usage qu'il en doit faire pour éviter l'erreur dans les sciences*, appeared in 1674 and in 1675 this work, revised and much enlarged (vol. iii appeared in 1678), passed through six editions during his lifetime and, in a Latin version, became famous throughout Europe. Antoine Arnauld, however, among others, questioned much of its theology, so Male-

ARCHIVES PHOTOGRAPHIQUES
MALEBRANCHE, ENGRAVING BY DE ROCHEFORT. 1707. IN THE BIBLIOTHEQUE NATIONALE, PARIS

branche amplified and explained himself in his *Traité de la nature et de la grâce* (1680).

A protracted and acrimonious controversy ensued and Arnauld, in his counter-reply *Traité des vraies et des fausses idées* (1683), attacked incisively much of what was essential and distinctive in Malebranche's metaphysics. After issuing a *Réponse* in 1684, Malebranche in 1688 published his *Entretiens sur la métaphysique et sur la religion*, wherein he resumes his philosophy in 14 dialogues of masterly composition, taking into account points previously contested. This is the best and a highly readable introduction to his system.

Besides further polemical writing, Malebranche conducted researches into the nature of light and colour, the foundations of the infinitesimal calculus and the psychological conditions of vision. His book *Des lois de la communication des mouvements* (1692) and the *Réflexions sur la lumière et les couleurs et sur la génération du feu* secured for him election to the Académie des Sciences in 1699. Malebranche died on Oct. 13, 1715, exhausted by four months of great suffering.

Malebranche's prose is justly praised for its lucidity and grace; Voltaire recommended it as a model of philosophical exposition. The *Méditations chrétiennes* (1683), the *Traité de morale* (1683; modern ed. by H. Joly, 1939) and the *Entretien d'un philosophe chrétien et d'un philosophe chinois* . . . (1708) deserve mention as well as the writings already cited. There are collected editions of Malebranche's works by Jules Simon (1842; 1853-59; and 1871), by D. Roustan and P. Schrecker (1928-) and by A. Robinet, et al. (1958-); and there is an edition of his correspondence with J. J. Dortous de Mairan by J. Moreau (1947). Modern editions of individual texts include those of *De la Recherche de la vérité* by G. Lewis (1945), of the *Entretiens sur la métaphysique et sur la religion* by A. Cuvillier (1948) and of the *Traité de la nature et de la grâce* by G. Dreyfus (1958). There is also an English translation of the *Entretiens* of 1688 by M. Ginsberg (1923).

METAPHYSICS

Accepting many of the essential principles of Descartes, Malebranche sought to correct and to supplement the deficiencies of Cartesianism (see DESCARTES, RENÉ; also BODY AND MIND) and to harmonize it with the main contentions and spirit of St. Augustine's teaching. Descartes had already hesitantly foreshadowed and inconsistently applied a form of occasionalism (*q.v.*) which, completely developed by Malebranche, formed the ontological basis of the latter's famous epistemological doctrine that "we see all things in God."

All changes, whether of bodies (motions or alterations) or of minds (successive thoughts or volitions), are directly due, not as popularly supposed to those bodies or minds themselves, but to God. For a body at rest cannot set itself in motion or move another, since it is possessed only of extensity and shape, and these cannot determine in what direction or with what velocity it shall move. But if it is to move, it must be in one and no other direction and with a determinate velocity that it does so. Neither can a body exist at a moment unless it exists in one determinate place and at determinate distances from other bodies; therefore its rest in the place where it is, or its motion if it be moving, must have been imparted to it by God in creating it. Further, the continuance in existence of that created body can be only a successive re-creation of it: it exists only so long as God wills to conserve it. But on each occasion of its re-creation it must be re-created somewhere; if re-created in the same place it is said to remain "at rest"; if at successively different places, to be "moving." Thus the motions and rests of all bodies at all times are directly due to God—"impact" of one body on another being but the occasion upon which God "moves" that other (*i.e.*, re-creates it in a different place). What we commonly designate "causes" are not causes but merely "occasions" on which the efficacy of divine volition is modified, and all uniformities and regularities in the course of natural change and productivity are but expressions of the general rules habitually followed by divine volition.

The inability of bodies and minds to interact is simply a special

case of the impossibility of interaction between created things in general. Minds are not causally dependent on our bodies; we could have been created without bodies yet having thoughts in succession. All created things—minds, bodies both animate and inanimate—are of themselves inert, wholly dependent upon God. Powerless too are "our" volitions (for they are not truly ours): when we will something, God, in certain circumstances, wills the same; but the effect follows from his, not from our, volition. Our sensory experiences have only a pragmatic value, warning us of harm or of benefit that may accrue to our bodies; they are false witnesses to the real natures of the things perceived. What we customarily regard as sensible qualities of perceived things are not qualities characterizing them independently, or at all; they are "sensations" or momentary modifications of our minds caused by God. Were we not embodied there would be no sensations or sensible qualities to appear deceptively as inherent in things.

Since minds are unextended and without locality, their modifications must be so too; hence sensory qualities (since Malebranche identifies them with sensations) cannot truly pervade or qualify bodies or their surfaces. As with Descartes, bodies possess no sensible characters. Indeed, bodies themselves are not "visible," says Malebranche (*i.e.*, never directly cognized or cognizable). What is directly cognized and mistaken for a body itself is really an idea representative of it, these ideas alone being the immediate objects, timeless and necessary, of our processes of temporal perceiving and thinking. Such idea-objects depend on us not for their existence but only for their being intermittently thought, and our greater or lesser attention to them accounts for the clarity or obscurity with which we know them. Being eternal, these idea-objects need no cause; being archetypes, they constitute together, in independence of our minds, that immutable, hierarchical order which is the divine reason and which God eternally contemplates.

All our ideas of various bodies are contained eternally in the one archetypal idea of the essence of matter which Malebranche calls "intelligible extension" (*i.e.*, infinite space as conceived in pure geometry and as being infinitely divisible into all possible shaped-extensities). Thus God's mind or reason contains ideas of all truths that we can ever discover; and "to see all things in God" is to be immediately aware of ideas that represent them. In this sense God is "the place of spirits just as space is the place of bodies." And not only do we see all things in God but God sees all things in himself, for these archetypal ideas are objects of his eternal contemplation as of our momentary perceptions. God's creation of bodies therefore comes to mean his actualization of certain (only) of the infinite number of possible shaped-extensities implicitly present in intelligible extension. So the vast variety of different determinate shapes present in our clear ideas of actual bodies is contained eternally in intelligible space, much in the same way, Malebranche says, as various statues are implicitly contained in blocks of unwrought stone. This unlimited possibility of creating countless bodies variously extended and differently shaped constitutes God's "immensity" or omnipresence; namely, that perfection or attribute of God of which "infinite intelligible extension" is the clear idea and an immediate object of his contemplation.

There is likewise an archetypal idea of mind. This too is an object of divine contemplation, as is the idea of intelligible extension; but it differs from the latter in that it is not also an object of human contemplation. Particular minds are implicitly contained in the one as are particular bodies in the other. Malebranche here reverses Descartes's conclusion that our clearest and surest cognition is that of our selves and that our knowledge of existent bodies, though clear, is only inferential and problematical. According to Malebranche we do not directly perceive our self by itself, and neither clear idea nor knowledge of its nature is attainable. Only of its existence have we assurance, and this is a "feeling" (*sentiment intérieur*). Thus can I know that I am but not what I am. Neither can other selves be known to us directly or by representative idea: we can but conjecture their existence by inference from analogy.

Descartes had also maintained that whereas knowledge of our nature and existence was an immediate certainty, undeniable and

indubitable, the existence of God was assured to us only mediately—by demonstration. Malebranche conversely affirms God's existence to be an immediate certainty needing no demonstration, but our own nature to be completely unknowable. God's nature cannot be known as other natures are, for there is no representative idea, archetypal or other, of God: his infinite essence, comprehending the perfections of all things, is incomprehensible by us. But from this infinite perfection we may deduce some of the divine attributes, though these will be understandable only equivocally and imperfectly. Here Malebranche is confronted with the difficulty of explaining how, if God's mind be essentially a changeless hierarchy of quasi-Platonic "ideas" constituting the orders of truth, wisdom and righteousness, he can be said to possess knowledge and volition. For even if God's knowing be timeless contemplation and not successively active, can divine volitions be so too? How can intervention which "alters" and "produces," thus ever changing the face of nature, issue from what is itself immutable? From this and connected perplexities Malebranche fails in the end satisfactorily to extricate himself.

Berkeley's idealism owes much to Malebranche and is essentially a synthesis of his philosophy with that of Locke, as Malebranche's was a synthesis of Descartes's with St. Augustine's.

MALENKOV, GEORGI MAKSIMILIANOVICH (1902—), Soviet Communist leader and close collaborator of Stalin, was premier from March 1953 to February 1955. He was born of middle-class parents on Jan. 8, 1902, at Orenburg, in Russia. He was still at school when the Bolshevik Revolution took place, and in 1919 joined the Red Army. In 1920 he joined the Communist Party and toward the end of the civil war was political commissar of the Bolshevik forces in Turkistan. In 1921 he resumed his studies, at the Moscow higher technical college, from which he received a diploma in 1925.

He had been in charge of the Communist organization in the college, and when he left he was appointed immediately to a post under the Central Committee of the Communist Party; he came into direct association with Stalin, became a member of Stalin's personal secretariat, and in 1932 was put in charge of it. From 1930 to 1934 he was in charge of the organization bureau of the Moscow party organization; and in 1934 he entered the organization bureau of the All-Union Communist Party. In this capacity he played an important role in the elimination of Stalin's opponents from the party through the "purges" of the 1930s. At the 18th congress of the Communist Party (1939) he was elected to the Central Committee and to membership both of the Orgburo (organization bureau) and of the Secretariat. In February 1941 he was made a candidate member of the Politburo. After the German invasion of the U.S.S.R. in 1941 he was appointed to the small State Defense Committee and was responsible for aircraft production.

In March 1946 Malenkov became a full member of the Politburo, second secretary of the Central Committee, and a deputy prime minister and was regarded as one of the small group of Stalin's closest collaborators. In 1947 he attended, along with A. A. Zhdanov, the meeting that founded the Cominform organization in Poland. At the 19th congress of the Communist Party in October 1952 he made the principal report in Stalin's place.

On Stalin's death in 1953 Malenkov was made chairman of the Council of Ministers (March 15) and retained briefly his position in the Party Secretariat. But he was soon replaced there by N. S. Khrushchev and he remained only a member of the Party Presidium. He thus lost control of the party apparatus, by means of which he had built his position in the Soviet state. His influence waned steadily in the ensuing conflicts. On Feb. 8, 1955, he was forced to resign from the premiership and to confess his responsibility for the unsatisfactory state of Soviet agriculture. He was

appointed to a minor ministerial post, in charge of power stations. At the Central Committee meeting in June 1957, at which the conflict between Khrushchev and the opposition to him reached a point of focus, Malenkov was denounced as one of the "anti-party group" and expelled from the Central Committee and its Presidium. He was subsequently reported to have been put in charge of a power station at Ust'-Kamenogorsk. In 1964 it was casually disclosed that he was no longer even a member of the Communist Party. (D. Fb.)

MALESHERBES, CHRÉTIEN GUILLAUME DE LAMOIGNON DE (1721-1794), French administrator and statesman respected for his policy of tolerance in the last decades of the *ancien régime*, was born in Paris on Dec. 6, 1721, the son of the future chancellor Guillaume de Lamoignon (see LAMOIGNON). He became a counselor in the Paris *parlement* in 1744 and premier president of the *cour des aides* in 1750. In the same year his father, then chancellor of France, made him *directeur de la librairie* or head of the press censorship. In this function (till 1768) Malesherbes gave effective protection to the *philosophes* of the Enlightenment. He made it possible for the *Encyclopédie* to continue to appear and to circulate in France works that had been printed abroad in order to evade the censorship.

An opponent of the chancellor René de Maupeou's *coup d'état* against the Paris *parlement* (1771), Malesherbes was exiled to his lands at Ste. Lucie, near Pithiviers. When the *parlement* was restored under Louis XVI (1774) he resumed his presidency of the *cour des aides* till he became secretary of state for the royal household (July 1775). This latter appointment made him responsible for the police, for ecclesiastical affairs and for a considerable part of the government of Paris and of the provinces, as well as for the household's concerns. He gave disinterested, but hardly energetic support to Turgot's reforming activities, devoted himself to prison reform and did much to control the misuse of *lettres de cachet*, but he failed to win the king's support for many projects and resigned in April 1776.

A member of the Académie des Sciences from 1750, of the Académie des Inscriptions from 1759 and of the Académie Française from 1775, Malesherbes divided the following years between travel in Switzerland, Germany and Holland, literary and botanical studies and campaigning for the recognition of the civil status of Protestants. He also produced a memorandum for the king on the political and economic situation. He was readmitted to the king's council in 1787-88, but without any secretaryship of state.

During the Revolution, Malesherbes emerged from retirement (Dec. 1792) to offer his services to Louis XVI, on trial before the Convention. He assisted François Denis Tronchet and Raymond de Sèze in the defense and broke the news of the verdict to Louis. Himself arrested in Dec. 1793 and condemned by the Revolutionary tribunal for counterrevolutionary activities, he was guillotined with his daughter and grandchildren, on April 22, 1794. Posthumous publications of his writings are *Mémoire pour Louis XVI* (1794), *Observations sur l'histoire naturelle de Buffon* (1796), *Mémoires sur la librairie* and *La Liberté de la presse* (1809).

BIBLIOGRAPHY.—F. A. de Boissy d'Anglas, *Essai sur la vie, les écrits et les opinions de M. de Malesherbes*, 3 vol. (1819-21); H. Robert, *Malesherbes* (1927); J. M. S. Allison, *Lamoignon de Malesherbes: Defender and Reformer of the French Monarchy 1721-1794* (1938).

MALET, CLAUDE FRANÇOIS DE (1754-1812) French general who conspired against Napoleon, was born at Danc in Franche-Comté on June 28, 1754, of a noble family. He joined the king's musketeers in 1771 but retired from military service on their dissolution in 1775. When the French Revolution broke out, his republican opinions alienated him from his family, and in 1791 he rejoined the army. Although he had held staff posts behind the lines and had been in action only once (Sept. 1793) he was promoted general after the crisis of Aug. 1799, when Gen. J. E. Championnet, organizing defenses in the Alps, had no one else to send to the Little St. Bernard pass. Napoleon gave him appointments in France and, from 1805, in Italy; but in May 1808, having been found guilty of contraband dealing, Malet was pensioned. He thereupon began to associate with malcontents in

Paris and was soon arrested; but from July 1810 he was allowed to live under surveillance in a private house in Paris. On Oct. 23, 1812, during Napoleon's absence in Russia, Malet left this house, obtained his uniform and announced at the barracks of the 2nd Paris guard that Napoleon had died and that he, Malet, was commandant of Paris for the provisional government. His story was accepted, and with a guards' escort he seized offices and released from prison two generals, the Provençal Maximilien Guidal and J. V. Moreau's friend Victor Fanneau de Lahorie. They arrested Savary, the minister of police. Malet went to the governor of Paris, Gen. Pierre Hulin, and shot him, but was himself seized by Col. Pierre Doucet. A court-martial condemned him and he was shot in Paris on Oct. 29, 1812. (I. D. E.)

MALEVICH (MALEVITCH), KAZIMIR (CASIMIR) (1878–1935), Russian painter, the founder of abstract painting, was born in Kiev on Nov. 2, 1878. In his early work he followed Impressionism as well as Fauvism and after 1910 was influenced by Picasso and Cubism. In 1913 Malevich started to follow his own line of painting by creating abstract geometrical patterns in a manner he called Suprematism. From 1919 to 1921 he taught painting in Moscow and Leningrad. In 1926 he visited the Bauhaus in Weimar, met Wassily Kandinsky and published a book on his theory under the title *Die gegenstandslose Welt* ("The Non-objective World"). Malevich first exhibited in the U.S. in 1924. When Russian politicians decided against modern art, Malevich and his art were doomed. He died in poverty and oblivion in Leningrad in 1935.

Malevich was the first to exhibit paintings composed of abstract geometrical elements; Piet Mondrian and Theo van Doesburg were influenced by him. One of his best-known paintings, "White Square on a White Background," is owned by the Museum of Modern Art, New York city; a number of other paintings are in the Stedelijk Museum in Amsterdam.

MALGACHE, RÉPUBLIQUE; see MALAGASY REPUBLIC.

MALHERBE, FRANÇOIS DE (1555–1628), French poet who described himself as "*un excellent arrangeur de syllabes*" but who was a greater poet than his reputation as a verse technician would seem to imply, was born at or near Caen in 1555. His father, a lawyer of ancient but impoverished nobility, had Protestant sympathies and the son received a Protestant education at Caen and Paris, and later at the universities of Basel (1571) and Heidelberg (1573). He was soon converted to a lukewarm Catholicism. His earliest surviving poems, in the style of the *Pléiade* (q.v.), date from 1575.

In 1577 he went to Provence as secretary to the governor, Henri d'Angoulême. There in 1581 he married Madeleine de Coriolis, the daughter of the principal judge of the *parlement* of Aix. In 1586 he returned to Normandy. His first published poem, *Les Larmes de saint Pierre*, a florid imitation of Luigi Tansillo's *Lagrime di San Pietro*, appeared in 1587. A second period in Provence began in 1595 and proved decisive in the forming of Malherbe's character and genius, mainly through his friendship with two great lawyers of Aix, the Stoic philosopher Guillaume du Vair and the polymath Nicholas Claude Fabri de Peiresc. In 1600 an ode to the new queen, Marie de Médicis, made his name more widely known.

It was in 1605 that Malherbe, now 50, went to Paris, supported by his friends Peiresc, Du Vair and Cardinal du Perron (q.v.). Henry IV was not greatly interested in poetry nor notably generous, but Malherbe soon attained the position of court poet and a modest living from court patronage. In his lodgings in the rue Croix-des-Petits-Champs he gathered a group of disciples, of whom Racan and François Maynard (q.v.) are the best known, and much of his critical influence was exercised in the form of sharp verbal thrusts, some of them preserved in Racan's life of him and in the pages devoted to him in Tallemant des Réaux's *Historiettes*. In 1626 his son Marc Antoine was killed in an affray and the loss affected him deeply. In pursuit of justice he followed Louis XIII

to La Rochelle and there, it seems, contracted the illness from which he died in Paris on Oct. 6, 1628.

Malherbe's prose writings consist of translations of Livy and Seneca, possibly suggested by Du Vair and illustrating his stoical temper; about 200 letters to Peiresc, of interest for their picture of court life; and the commentary on Philippe Desportes, Malherbe's marginal annotations on his copy of the works of the older poet (edited by F. Brunot, 1891; see *Bibliography*). These notes are detailed and entirely negative, fastening critically on minute points of workmanship. Nevertheless, certain positive principles emerge by implication: verbal harmony, propriety, intelligibility (loose syntax, dialectal expressions, obscure mythological allusions, mixed or extravagant metaphors are all condemned), above all the conception of the poet as craftsman rather than prophet.

Malherbe's own poetic work, which is not voluminous, may be divided into state poems; religious verse (*Les Larmes de saint Pierre* and a few Psalms); consolations (in which Malherbe specialized); love poems; and occasional verses. The first group bulks largest and in his mature period Malherbe appears as a poet laureate, a composer of official odes and panegyrics. He greets Marie de Médicis on her arrival in France, praises the military exploits of kings or ministers or writes love poems for courtiers. His main weakness lies in poverty of imagination: he wrote little and very slowly, his ideas, images and rhymes are repeated from one poem to another. But there is compensation for this painful labour in the dignity and even grandeur of his best poems. They offer little to the lover of the ingenious but give satisfaction through their harmony and monumental strength:

La terre en tous endroits produira toutes choses;
Tous métaux seront or, toutes fleurs seront roses,
Tous arbres oliviers.
("Récit d'un Berger," ll. 67–69)

This is what Baudelaire meant when he spoke of "*un vers de Malherbe, symétrique et carré de mélodie*." (*Curiosités Esthétiques*: *Pléiade* ed. by Y.-G. Le Dantec, p. 865).

Malherbe's influence on French poetry was profound. However, it must be remembered that his classical reforms were to some extent anticipated by Jean Bertaute, Du Perron and even Desportes himself, and that the general evolution of poetry is reflected in his own work, which is not all of a piece. But in essentials French verse retained the characteristics stamped on it by Malherbe up to the Romantic period and beyond.

BIBLIOGRAPHY.—The first collected edition, *Les Oeuvres*, appeared posthumously in 1630. The standard edition of the complete works is that of L. Lalanne, 5 vol. (1862–69); of the poems only, *Les Poésies*, ed. by P. Martinon (1926), ed. by J. Lavaud, 2 vol. (1936–37). See also R. Fromilhague, *La Vie de Malherbe (1555–1610)* and *Malherbe: Technique et création poétique* (both 1954); F. Brunot, *La Doctrine de Malherbe* (1891); R. Lebègue, *La Poésie française de 1560 à 1630* (1951); R. Winegarten, *French Lyric Poetry in the Age of Malherbe* (1954); F. Ponge, "Malherbe" in *La Nouvelle Revue française*, no. 45, pp. 434–440 (Sept. 1956), and in *Le Préclassicisme français* (*Cahiers du Sud*, 1952); J. Tortel, "Le Lyrisme au XVII^e Siècle," in *Encyclopédie de la Pléiade, histoire des littératures*, vol. 3, pp. 352–356 (1958).

(R. A. Sa.)

MALI, REPUBLIC OF (RÉPUBLIQUE DU MALI), is a landlocked republic in west Africa, until 1958 known as French Sudan (Soudan Français). It is bounded north by Algeria, west by Mauritania, Senegal and Guinea, south by Ivory Coast and Upper Volta and east by Niger. Pop. (1961) 4,100,000 including 7,000 Europeans. Area 463,947 sq.mi. (1,201,625 sq.km.).

Physical Features.—The republic covers much of the southern Sahara, with the vast plains of the Tanezrouft and Taoudenni in the north and those of Meriyé and Azaouak in the south. The only marked relief is in the east, where the Adrar des Iforas rises in rounded granites and ruiniform heights to about 2,000 ft. above the neighbouring plains. This region is more moist and has pastures which allow the Tuareg to raise cattle. In the south the Sahara gives place to the Sahel, where the annual rainfall is 4–8 in. and lasts regularly for two months. The dunes are covered with cram-cram (*Cenchrus biflorus*), mimosa, clusters of doumpalms (*Hyphaene thebaica*) and palmyra (*Borassus flabellifer*). In this region is the great bend of the Niger river. In the west this forms

the immense interior delta of the Macina, where branches spread and communicate in time of flood with isolated lakes such as Faguibine and Débo. The district is partially inundated in time of flood, which in January reaches the vicinity of Tombouctou (Timbuktu).

Only toward Gao in the east does the Niger valley contract. In the Sahel are shepherds, including Tuareg and Moors who seek dry-season pastures and Fulani (Peul) who move their herds from the river to the dry plains. Cultivators include the Sarakolé (Soninke) in the west and the Songhai, who grow millet and rice along the Niger; river fishing is done by the Bozo and Somono (Bambara). Where the annual rainfall exceeds 20 in. and lasts longer than three months the Sahel gives way to savanna, which covers all the southern part of the republic. It extends over wide plains of alluvium or laterites covering ferruginous beds, dominated by plateaus of Primary sandstone. The Mandingo plateau between upper Senegal and the Niger continues eastward toward Upper Volta and northeast along the right bank of the Niger through the Dogon plateaus and Bandiagara cliffs and the knolls extending them to Hombori. The main axis of the savanna zone is still the Niger and its right-bank affluent, the Bani. But the inhabitants are also distributed between the rivers, with peasants on the plateau escarpments (the Dogon and Bambara in the northern plains) and the Mandingo more to the south; Fulani populations have settled among them.

The climate is tropical and there is no real winter. The dry season (November to April) is marked by the hot, dust-laden wind known as the harmattan. Wildlife includes lions, hippopotamuses and antelopes.

(J. D.)

The People.—The most important ethnic group, numbering about 1,200,000, is that of the peoples speaking Mandingo dialects. Of these, the Malinké and Dioula are Muslims and the Bambara are mostly pagans. Other groups such as the Sarakolé and Bozo speak languages derived from Mandingo and are also Muslims. The Dogon of the Bandiagara escarpment, the Senufo and the Sikasso practise paganism with a great variety of myths and ceremonies. The Songhai, Muslims living along the Niger, speak a language of independent stock. Some of the inhabitants from neighbouring republics (the Tukolor or Toucouleur of Senegal and the Mossi peoples and Bobode of Upper Volta) have spread into Mali. All these peoples are Negroes and essentially agriculturalists, dwelling in the southern zone or on the banks of the Niger. Millets are the principal crop and cattle and sheep are bred. Among these peoples are artisan castes (smiths, woodworkers, leatherworkers, potters) and a caste of *griots* or magicians. The Dioula are merchants and are found in all regions; the Bozo and some of the Songhai groups are exclusively fishermen.

The Fulani are all stockbreeders, occupying various territories in the semiarid steppes. Originally fair-skinned, having dwelt in the desert in prehistoric times, they are now much crossbred. They share their language with the Tukolor. Most of them are Muslims and the rest pagans.

The desert zone is inhabited by two peoples of white race, occasionally somewhat crossbred: the Tuareg and the Moors. Both groups are Muslim and subsist by nomadic stockbreeding of cattle and camels. The Tuareg in the northeast speak a Berber dialect and their Islamic creed is mixed with paganism; they have spread south of the Niger. The Moors speak Arabic; Muslim brotherhoods play an important part in their lives. Most of the Moors in this part of Africa live in Mauritania, but the Kounta and Berabish tribes live as nomads in Mali north of Tombouctou.

It is estimated that 63% of the republic's population are Muslims, 36% are animists and 1% profess Christianity. (See separate articles on the principal groups or tribes.)

History.—Evidence of prehistoric habitation of the Malian Sahara is furnished by Paleolithic and Neolithic remains and by rock paintings and carvings. The "Asselar man," the earliest human fossil with Negroid features, was discovered in 1927 about 250 mi. N. of Tombouctou. Elsewhere in Mali have been found Mousterian remains, raised stones of the Neolithic period and, along the Niger, numerous traces of protohistoric civilizations.

From the early middle ages caravan routes between the bend of

PAUL CONKLIN—PIX FROM PUBLIX

GROUNDAN, ONE OF THE LARGEST CITIES IN THE MID-NIGER BASIN, REPUBLIC OF MALI. IT CHIEFLY TRADES IN GUM AND HIDES

the Niger and Morocco and southern Algeria carried ivory, gum, ostrich feathers, slaves and gold. Around the starting points of these routes were founded the Sarakolé empire of Ghana (8th–13th centuries) between the Niger and Senegal rivers, and the Mandingo empire of Mali (13th–16th centuries, from which the republic derives its name), on the upper and middle Niger. (See *AFRICA: History: Sahara and Sudan: Empires of Mali and Gao*.) In the 15th century the Songhai in the Tombouctou-Gao region gained their independence and spread their rule over much of the country extending eastward to the Hausa kingdoms. The Songhai power was in 1591 broken by the Moroccan army of Ahmed IV al-Mansur, and Tombouctou remained under the Moors for another two centuries. Thereafter, the Niger valley was divided between the Tuareg in the region of Gao, the Fulani in Macina and the Bambara in the kingdom of Ségou.

The 19th century was marked by the resurgence of Islam and by the French conquest from Senegal. Between 1848 and 1864 Omar el-Hadj absorbed the Bambara and Fulani kingdoms; his son Ahmadou reigned at Ségou. The French had occupied upper Senegal, and in 1881–83, Col. Gustav Borgnis-Debordès seized Kita and built a fort at Bamako. Later, Col. J. S. Gallieni compelled Ahmadou and Samory to accept a French protectorate.

Under Gallieni's successor, Col. Louis Archinard, the struggle was resumed. Between 1888 and 1893, Ségou was captured, Ahmadou put to flight and Samory driven back to the Ivory Coast. In Dec. 1893, Lieut. H. G. M. Boiteux occupied Tombouctou with a flotilla. The Tuareg massacred the column under Col. T. P. E. Bonnier advancing to reinforce Boiteux, but the situation was saved by Col. (later Marshal) J. J. C. Joffre. In 1899 French trading posts were established at Gao and downstream of it. The southern Sahara was pacified by *meharists* ("camel companies"). The capture of Sikasso in 1898 completed the conquest of the country which as French Sudan became a territory of French West Africa. The territory was divided into *cercles* ("districts") in which civilian administrators gradually replaced military officers. The Sudanese—particularly the Bambara—provided contingents of sharpshooters called *Sénégalais* who played a leading part in the French colonial wars. Road and rail communications were established and in 1925 the first automobile crossing of the Sahara was made.

In 1946 French Sudan became an overseas territory of the French Union and was given a territorial assembly, followed in 1957 by an elected government. As the Sudanese Republic (Soudan) the country was proclaimed an autonomous state of the French Community on Nov. 24, 1958. In the following year it joined with Senegal to form the Mali Federation, which was dissolved in Aug. 1960. In September the country was proclaimed as an independent republic. French troops in 1961 evacuated their bases, and although Mali remained outside the French Community, agreements were made providing for French technical and cultural assistance. Agreements relating to trade, loans or aid were also made with the United States, the U.S.S.R., the People's Republic of China and Czechoslovakia. In July 1961 Mali joined Ghana

and Guinea in the Union of African States, designed to foster friendship and co-operation and to provide mutual assistance in the event of aggression. In Jan. 1963 Mali signed a mutual assistance treaty with Ivory Coast and in May became a founder-member of the Organization of African Unity. Frontier agreements with Mauritania also were signed and better relations with Senegal were established.

(Hu. De.)

Administration.—The Sept. 1960 constitution describes the Republic of Mali as being "indivisible, democratic, secular and social." Legislative power rests with a national assembly elected for five years by direct universal suffrage. The president, who is the head of state, is vested with executive power. He is designated by the assembly for five years and chooses his council of ministers, which includes the premier. In the 1959 election the Union Soudanaise party won all 80 seats in the assembly. French is the official language.

Mali's judicial system was being reorganized in the 1960s. There are three tribunals of first instance, at Bamako, Kayes and Ségou; eight courts of the peace with broad jurisdiction, at Gao, Mopti, Sikasso, Tombouctou, Bougouni, Koutiala, Niore and San; and also courts of the peace with limited powers and ordinary police courts, destined to disappear under the reorganization. The court of appeal for penal, civil and commercial cases is at Bamako.

In the early 1960s there were more than 350 primary schools with about 55,000 pupils, 13 secondary schools with 2,500 students and 4 technical schools with an enrollment exceeding 1,000. In Bamako there are the Islamic Research institute, a veterinary school, a leprosy and trachoma institute and a national trade school (for training African artisans, especially in gold, silver, leather and ivory work).

Economy.—The savanna zone is the most active. Its wealth derives from the cultivation of food crops (millets, rice) along the river and from herding. Progress has been made in agricultural techniques and controlled agriculture, with cassia trees planted to regulate rice cultivation along the river. The Office du Niger was established by the French administration to utilize the Macina downstream of Ségou, with a dam at Sansanding to raise the level so that water may be directed into canals on the left bank. There, more than 30,000 peasants have been settled to grow rice and, in a small way, cotton on 52,000 ha. of irrigated land; but results have not always reached expectations. Together with cotton and peanuts, Mali exports foodstuffs (rice, meat, fish) to neighbouring countries. Livestock, which includes about 3,125,000 cattle and 12,000,000 sheep and goats, is the main resource. Some animals are exported to Senegal, Ghana and Ivory Coast, while leather and hides are exported to France. Supplies of Mali rice have enabled Senegal to do without rice from the far east. There is a caravan trade in salt, which is exploited around Taoudenni.

Although manganese and bauxite exist in quantity, deposits remain unexploited because of their remote location in the interior. Mali's inland situation also explains the importance of communications with its neighbours. It is linked with Senegal and Dakar by the metre-gauge Dakar-Niger railway, which is continually under improvement and reaches the Niger at Bamako, and by a metalled road parallel to the railway for most of its length. Upstream of Bamako the Niger is navigable as far as Kouroussa in Guinea; downstream it winds past the Sotuba rapids, reaching at Kulikoro a stretch that can be navigated to Kabara, the port of Tombouctou (q.v.), and beyond Gao. The road system has been improved and is extended by the trans-Saharan track between Gao and Colomb-Béchar, Alg. Radio Mali at Bamako broadcasts in French and Bambara.

Bamako (q.v.), the capital, serves as a great redistribution market, particularly for cola nuts. Kayes has an active trade in livestock to Senegal. The other towns are also markets; some, like Djenné, of diminishing importance, others favoured by their situation on or near rivers (such as Tombouctou, Mopti, Ségou and San), or on roads (Sikasso), or on both (Gao). Scheduled air services link Bamako with Dakar, Senegal, and with the main centres in Ivory Coast.

After brief membership (May–June 1962) in the West African Monetary union, Mali withdrew but remained in the franc area.

See also references under "Mali, Republic of" in the Index. Current history and statistics are summarized annually in *Bri-tannica Book of the Year*.

(J. D.)

MALI FEDERATION, a short-lived union between the autonomous territories of the Sudanese Republic and Senegal in west Africa. The federation took effect on April 4, 1959, achieved complete independence on June 20, 1960 (remaining within the French Community), and was dissolved by Senegal's secession on Aug. 20, 1960. Thereafter both countries became independent republics, Senegal continuing within the French Community and the Sudanese Republic becoming the Republic of Mali. See MALI, REPUBLIC OF; SENEGAL, REPUBLIC OF.

(Hu. De.)

MALIK IBN ANAS (c. 715–795), Muslim jurist, whose work laid the foundations for one of the four orthodox schools of Islamic law, the Maliki, which now predominates in north and west Africa and in Upper Egypt. He lived most of his life in Medina where he studied jurisprudence under Rabi'a ibn Farrukh. Rising to a position of eminence in Medina, he gave support to the rebellion of Mohammed ibn 'Abd Allah against the caliph al-Mansur in 762 by declaring in a *fatwa* (a formal legal opinion given by a jurist of standing) that the allegiance pledged to al-Mansur was not binding, because it had been given under compulsion. After the failure of Mohammed's rebellion, Malik was punished by flogging but subsequently regained the favour of the caliphs as indicated by the visit of the celebrated Harun al-Rashid during the latter's pilgrimage to Medina in 795. Malik died in the same year and was buried at al-Baqi'.

Malik is known chiefly for his composition of the *Kitab al-Muwatta'* ("Book of the Leveled Path"), one of the earliest surviving lawbooks. In his work he attempted to survey and systematize Islamic law according to the consensus prevailing in Medina and to provide principles for the resolution of disputed points. He gave precedence to the Medinan practices and traditions over the more generally prevailing traditions and exercised independent judgment in cases in which there was no clear guide. His main contribution, however, was systematization rather than personal interpretation. See also ISLAMIC LAW. (H. B. PA.)

MALIK SHAH (1055–1092), third and most famous of the Seljuk sultans (see SELJUKS), was born on Aug. 6 or 16, 1055. He succeeded his father, Alp Arslan, in 1073 under the tutelage of the great vizier Nizam al-Mulk (q.v.), who was the real manager of the empire until his death. Malik Shah had first to overcome a revolt of his uncle Qavurt (Kavurd) and an attack of the Qarakhanids of central Asia on Khurasan; thereafter he consolidated and extended his empire more through diplomacy and the quarrels of his enemies than by actual warfare. He suppressed the former vassal principalities of upper Mesopotamia and Azerbaijan, acquired Syria and Palestine, and established a strong protectorate over the Qarakhanids of Bukhara and a measure of control over Mecca and Medina, Yemen and the Persian gulf territories. His control of the Turkmens of Asia Minor was contested by a rival Seljuk dynasty.

With the encouragement of Nizam al-Mulk, Malik Shah displayed a great interest in literature, science and art. His reign is memorable for the splendid mosques of his capital Isfahan, for the poetry of Omar Khayyam and the reform of the calendar. His people enjoyed the blessings of internal peace and religious tolerance.

There were however shadows amidst this glory. His brother Takash, governor of Khurasan, revolted and was imprisoned and blinded. Under the leadership of Hasan ibn al-Sabbah there arose the antiorthodox terrorist movement of the Assassins who murdered Nizam al-Mulk in 1092. Before this he was partly estranged from his vizier who favoured the claims to succession of Malik Shah's eldest son by his first wife against those of a son by his second wife, Turkan Khatun. Further, his relations deteriorated with the caliph of Baghdad who had married his daughter and neglected her. He had ordered the caliph to leave Baghdad when he himself died there suddenly in Nov. 1092. After his death his empire quickly disintegrated through internal quarrels.

(Cl. CA.)

MALINES: see MECHELEN.

MALINKE, a west African people (known also as the **MANDINGO** proper) occupying parts of Guinea, Ivory Coast, Mali, Senegal, Gambia and Portuguese Guinea. Their population in the 1960s was estimated at 1,500,000, of whom about one-fifth are Muslims. They are sedentary farmers and cattle herders, with millet as their main food. Politically they are divided into numerous independent states ruled by hereditary kings (*mansa*). One of these, the king of Kangaba (in modern times a small town on the upper Niger river), represents one of the world's most ancient dynasties still in power, a dynasty which has ruled for 13 centuries with a single interruption of 15 years (1285–1300). Beginning in the 7th century A.D. as the centre of a small state, Kangaba became the capital of the great Malinke empire known as Mali (Melle). This was the most powerful and most renowned of all the empires of the western Sudan, indeed the largest of African empires, now memorialized in the name of the Republic of Mali.

In the 11th century the king of Kangaba was converted to Islam and made a pilgrimage to Mecca, establishing new trading relations. Thereafter his mines became the principal source of gold for the Moroccan caravans which had formerly traded with ancient Ghana, and Mali's growth began. Mansa Musa, who ruled from 1200 to 1218, made four pilgrimages to Mecca. Musa's grandson, Mari Djata, conquered the Susu (*q.v.*) in 1235 and destroyed the capital of Ghana in 1240. Each king in turn made a pilgrimage to Mecca and enlarged the empire, including a serf, Sakura, who usurped the throne (1285–1300) and conquered Jenne and the Tukulor.

The most celebrated pilgrimage was that of the greatest Malinke king, Mansa Gongo-Musa, which aroused great interest at Cairo and Mecca in 1324. Malinke chroniclers record that his caravan included 60,000 persons and his camels carried 12 tons of gold. Gongo-Musa added Timbuktu and Gao to his realms, bringing Mali to the height of its power. In 1332, in the reign of Mansa Suleiman, the capital was visited by Ibn Batutah (*q.v.*), who described its wealth, pomp and extent. During the 14th century Mali controlled much of the Sahara and most of the Sudan west of Gao. It declined during the 15th century as the Songhai empire expanded, and was conquered by Songhai in the war of 1501–13. See also **MANDINGO**; **MALI**, **REPUBLIC OF**.

See *West African Directory* (published annually). (Wt. B.)

MALINOWSKI, BRONISLAW KASPER (1884–1942), Polish-born British anthropologist, one of the leading figures in the development of modern social anthropology, was born on April 7, 1884, in Cracow. Attracted to anthropology by Sir James G. Frazer's *The Golden Bough*, he studied at the University of Cracow (Ph.D., 1908), Leipzig university and the London School of Economics, where he successively became lecturer, reader and first professor (1927–42) of social anthropology. His analyses of Melanesian society, based upon four years of field work in the Trobriand Islands and northwest Melanesia (1914–18), set a standard of depth and comprehensiveness that revolutionized field research and gained him a world-wide reputation. His functional approach to the study of societies, which he saw as integrated systems of institutions subserving basic and derived needs, drew into the discussion of anthropological theory specialists in a wide range of human studies from law to psychology, and did much to obtain a secure position for anthropology in British university curriculums. He also was a pioneer in applied anthropology, and many of the British advances in colonial administration stemmed from the inspiration he gave scholars and administrators from Africa and Asia. His talent attracted to his seminars almost all the leading British specialists of the first half of the 20th century. His contributions to *Encyclopædia Britannica* include **MARRIAGE**, **PRIMITIVE**. From 1939 until his death at New Haven, Conn., on May 16, 1942, Malinowski was visiting professor of anthropology at Yale university.

His studies include *The Family Among the Australian Aborigines* (1913); *Argonauts of the Western Pacific* (1922); *Sex and Repression in Savage Society* (1927); *Coral Gardens and Their Magic*, 2 vol. (1935); *The Foundations of Faith and Morals* (1936); works which were published posthumously include *A Sci-*

entific Theory of Culture (1944); *The Dynamics of Culture Change* (1945); *Magic, Science and Religion* (1948); *Freedom and Civilization* (1960).

MALIPIERO, GIAN FRANCESCO (1882–), Italian composer, born in Venice on March 18, 1882. He studied harmony at the Vienna conservatory in 1898 and later composition at Venice and Bologna under Enrico Bossi. In 1921, after a journey to Paris where he was influenced by contemporary French music, he was appointed professor of composition at Parma conservatory. Subsequently he became director of the Istituto Musicale Pollini at Padua and in 1939 director of the Liceo Marcello in Venice. With Alfredo Casella he played a leading part in Italian music in the 1920s. Rebelling against the principles of *verismo*, the realistic aesthetic that inspired Puccini, he rediscovered the qualities of Italian preromantic music. His work reflects the spirit of 17th- and 18th-century Venetian music and his operas, inspired by Claudio Monteverdi, represent a fusion of modern and archaic styles. His instrumental music avoids both development of themes and contrapuntal elaboration.

His most important stage works include *L'Orfeide* (1918–22), *Torneo notturno* (1929), *I capricci di Callot* (1941–42) and *Venere prigioniera* (Florence, 1957). His symphonic music includes symphonies, the three sets of orchestral pieces entitled *Impressioni dal vero* (1910–22), and the *Pause del silenzio* (1917). Among his chamber works are seven string quartets and works for various instrumental groups. Between 1926 and 1942 he published the complete works of Monteverdi (16 vol.) and later collaborated in the collected edition of the works of Vivaldi.

See M. Bontempelli, *Gian Francesco Malipiero* (1942); G. M. Gatti, *L'Opera di Gian Francesco Malipiero* (1952).

MALLARMÉ, STÉPHANE (1842–1898), French poet, the leader and greatest poet of the Symbolist movement (see **SYMBOLISTS**). was born in Paris on March 18, 1842. Educated at Passy and the Lycée de Sens (renamed Lycée Mallarmé in 1961), he passed his *baccalauréat* in Nov. 1860. His family traditionally registered and taxed real estate transactions; he preferred teaching, but his passion was for poetry. To perfect his English, he went to London in Nov. 1862 with Maria Gerhard a German governess he had met in Sens. After many channel crossings and much heart searching, they were married at the Brompton oratory, London, on Aug. 10, 1863. They had two children, Geneviève (1864–1919) and Anatole (1871–79). In Sept. 1863 Mallarmé qualified as a teacher of English: but he never obtained a *licence* or doctorate. His career, though a long martyrdom, was reasonably successful: he taught in Tournon (1863–66); Besançon (1866–67); Avignon (1867–70); and in various Parisian *lycées*, Fontanes-Condorcet (1871–84), Janson-de-Sailly (1884–85) and the Collège Rollin (1885–93). He revisited England in 1871, 1872 and 1875. In 1875–76, through Arthur O'Shaughnessy (*q.v.*), a friend and admirer of the Symbolist poets, he contributed anonymously to the London *Athenaeum*. His many English friends and correspondents included Swinburne. His cottage at Valvins a village on the Seine near Fontainebleau, became his favourite holiday haunt from 1874 and, after his retirement in Jan. 1894 his main residence. He enjoyed sailing on the river and loved the autumnal splendour of the forest. From about 1880 he held in his tiny Paris flat his famous Tuesday receptions, the "*Mardis de la rue de Rome*," attended by André Gide, Paul Claudel and Paul Valéry, and by the Symbolist poets Henri de Régnier, Gustave Kahn, Francis Vielé Griffin and Stuart Merrill. Like Baudelaire, Mallarmé loved all the arts, especially painting, music and ballet. He defended Édouard Manet (*q.v.*) against the hostility of his critics: Manet painted his portrait and illustrated his work, and Manet's model, Méry Laurent, inspired some of Mallarmé's most exquisite poems. Later Whistler was his friend, and Mallarmé translated his *Ten o'Clock* (1888). From 1885, Mallarmé attended the Concerts Lamoureux and wrote for Édouard Dujardin's *Revue*

Wagnérienne. In 1890 he toured Belgium, delivering a noble funeral oration on his friend Villiers de l'Isle Adam (q.v.); in 1894 he lectured in Oxford and Cambridge on music and letters. In 1896 he was elected prince of poets in succession to Verlaine. He died, aged only 56, at Valvins on Sept. 9, 1898.

Works.—Mallarmé began writing poetry early. In 1859–60 he wrote a group of 55 poems entitled "Entre quatre murs" (of which 40 were first published in 1954): they imitate Lamartine, Musset and Hugo. He also compiled a vast anthology, including 9 poems by Edgar Allan Poe and 29 from *Les Fleurs du Mal* by Baudelaire, who decisively influenced Mallarmé's first truly creative phase. This culminated in 11 poems published in the *Parnasse contemporain* of 1866, edited by Catulle Mendès. Mallarmé described these as "intuitive revelations of [his] temperament"; the clash between the ideal and the real is expressed with great intensity and subtlety by means of the Baudelairean technique of *correspondances* between sensations, emotions and ideas. A severe crisis followed. Mallarmé's religious faith faded before "the terrible light of Science." But he soon found a new and enduring faith: "Beauty alone exists, and it has only one perfect expression, Poetry." He planned a great book which would embody in symbolic form his vision of the evolution of beauty through innocence and experience to a serene synthesis. His poem *Hérodiade*, begun in 1864, before the crisis, was to be its "overture." A dialogue between Hérodiade and her earth-bound nurse appeared in the second *Parnasse contemporain* in 1871: the untamed virgin with her massive golden hair, her great mirror and her fierce quest of inviolable purity, is evoked in language of incomparable harmony and splendour, dominated by images of jewels, of ice and snow, and chill, glittering stars. In complete contrast stands Mallarmé's other poetic masterpiece, *L'Après-midi d'un faune*, begun in 1865, rejected in 1875 by the editors of the third *Parnasse contemporain*, and published in 1876 by Mallarmé in a sumptuous rare edition illustrated by Manet. In the shimmering heat of a drowsy summer afternoon a young faun recreates his vision of two nymphs, one fair blue-eyed and chaste, the other dark and sensual, who had escaped from his embrace. The poem exemplifies in verse of extreme musicality the power of art to evoke, by means of sublimated reminiscences, the ideal essence of fleeting phenomena. It inspired Debussy (q.v.) to write the work called after it (1894). In the *Toast funèbre* (1873), commemorating Théophile Gautier, and the enigmatic *Prose pour des Esseintes* (1885), poetry is extolled in flower symbolism of great beauty, as the means of recreating Eden. In 1887 Mallarmé "published" his *Poésies* in a photolithographic facsimile of his manuscript, limited to 40 copies. Thenceforward, apart from a number of adamant sonnets, he wrote comparatively little serious poetry, but much charmingly witty and frivolous light verse, including postal addresses in the form of quatrains, later collected in the *Vers de circonstance* (1920).

Mallarmé wrote some exquisite poems in prose, first published in *La Revue des lettres et des arts* (1867–68). "Les Poèmes d'Edgar Poe" first appeared in *La Renaissance artistique et littéraire* (1872) and *La République des lettres* (1876–77): they were later (1888) published by Edmond Deman of Brussels, a man after Mallarmé's own heart, who also brought out the prose volume *Pages* (1891) and the posthumous *Poésies* (1899). In 1874 Mallarmé produced singlehanded eight numbers of the fashion review, *La Dernière Mode*, in which he first tried out his highly original prose style, further developed in his preface to William Beckford's *Vathek* (1876). *Les Mots anglais* (1877) is a curious study of English vocabulary, exploring connections between the sound and sense of words. *Les Dieux antiques* (1880), adapted from several works by George W. Cox, interprets all myths as solar phenomena. Mallarmé contributed to *La Revue indépendante* (1885–88), W. E. Henley's *National Observer* (1892–93) and *La Revue blanche* (1894–97). After the anthology *Vers et prose* (1893), with a portrait by Whistler as frontispiece, he published in 1897 his collected prose under the title *Divagations*. The same year saw his poem "Un Coup de Dés" published in the review *Cosmopolis*; it is a bold experiment in typography, in which various interlocking themes are set out in types of different size. It is not

the great work planned in 1866, nor even part of it: on the eve of his death Mallarmé ordered the destruction of his notes in terms implying that the work proper remained to be begun. His swan song was the beautiful "Cantique de saint Jean" (first published in the posthumous *Poésies* of 1913): the saint proclaims the triumphal liberation of his spirit by death.

Status as Poet and Critic.—Mallarmé has steadily risen to a high place in the history of French poetry. His life was one of exemplary dedication to his art and for many of his contemporaries he was the incarnation of the ideal poet. His poems are few, but they have a musical perfection that makes them immediately and enduringly memorable, while their magic density constitutes a challenge to find meanings worthy of their form—a condition too often overlooked by his commentators. His critical theories have exercised a deep and lasting influence. He distinguishes among the different functions of language and rejects narration, description and instruction as proper tasks for poetry, whose primary role he sees as the imaginative creation of metaphorical relationships. He insists that poetry should recapture from music the art of evocation and suggestion while retaining its own supremacy as the intelligible "word." His correspondence reveals his exquisite courtesy, his delicate wit and irony, his genius for friendship, his generosity toward his fellow artists and the central position he held in the literary and artistic life of Paris.

MALLEABLE CAST IRON: see CAST IRON.

MALLECO, an inland province of southern Chile in latitude 38° 15' S.; area 5,442 sq.mi.; pop. (1960) 174,300, of whom several thousand are Araucanian (Mapuche) Indians. Malleco was created out of Arauco province in 1887, absorbed by Bío-Bío and Cautín provinces in 1927 and then formed again in 1937. The province embraces coastal range, central valley and cordilleran terrain. The cordilleran ridges and volcanoes (Tolguaca, Lonquimay and Llaïma), forests, lakes and hot springs (Tolguaca, Río Blanco and Manzanares) are prime attractions for summer vacationers. However, recreation is of secondary economic importance to farming, stock raising and lumbering. The processing industries, based upon agricultural and forest products, are centred in the provincial capital, Angol (pop. [1960] 18,637) and in the lesser administrative and commercial centres of Victoria, Traiguén, Curacautín and Collipulli. The main north-south railway, and its branches, and seasonal roads serve these communities. (J. T.)

MALLOPHAGA, an order of insects comprising the biting or chewing lice; minute, wingless forms parasitic on birds and mammals. They are sometimes treated as a suborder along with Anoplura, the sucking lice, to form the order Phthiraptera. About 2,800 species are recorded, with many more, especially among the bird lice, still undescribed. Their life cycle is spent on the feathers or hair of the host, though one genus lives in the throat pouches of pelicans and cormorants.

The eggs, attached to the feathers or hairs, or occasionally laid inside quill feathers, give rise to young which pass through three nymphal stages which resemble the adult. A single bird or mammal species may be parasitized by one or more (sometimes as many as 15) species of biting lice. They often show host-specificity, being unable to survive on any but their own or a related host. Their present distribution suggests that they became parasitic at

BRITISH MUSEUM (NATURAL HISTORY)

ELEPHANT LOUSE (HAEMATOMYZUS ELEPHANTIS)

an early stage in the evolution of their hosts and evolved with them so that, with some exceptions due to subsequent transference having taken place, related hosts are parasitized by related biting lice; a particular genus may be restricted to one group of birds, and a particular species may be found on only one species of bird or on a group of related species.

Biting lice on birds feed on feathers or feathers and blood, the blood sometimes being taken from the shafts of the developing feathers; some live on blood alone and their normal chewing mandibles may then be adapted to piercing the skin. Probably all species of birds have biting lice. Preening keeps down the numbers, and birds with damaged bills are often particularly heavily infested because they cannot preen themselves properly. Normally, lice do no damage, but if they are too numerous the irritation may cause the bird to damage itself by scratching and may even interfere with egg production and fattening in poultry.

Biting lice parasitic on mammals feed on skin secretions and skin debris; it is uncertain whether they eat hair. They are less widespread than those of birds, comprising fewer genera and species, and occur on marsupials, primates, rodents, land carnivores, hyraxes and ungulates. The elephant louse, *Haematomyzus*, if of questionable affinity, is usually considered to belong to the Mallophaga. See LOUSE.

See M. Rothschild and T. Clay, *Fleas, Flukes and Cuckoos*, 3rd ed. (1957). (T. CL.)

MALLOW (MALA), a town, urban district, rail and road junction of County Cork, Republic of Ireland, lies astride the Blackwater river, 149 mi. S.W. of Dublin and 22 mi. N. of Cork by road. Pop. (1961) 5,545. The ford was defended by a castle built by the Desmonds, the ruins of which remain in Castle park. Mallow received a charter of incorporation from James I, and in the 19th century it was a popular spa and was known as "the Bath of Ireland." The medicinal spring is still there, but the spa house is no longer used. Thomas Osborne Davis, the poet, and William O'Brien, Irish patriot, were born in Mallow. The town is the market centre for a rich agricultural region and has factories for mineral waters (soft drinks) and condensed milk, cornmills and tanneries, and there is a large sugar-beet factory to the west. Mallow is also known as an angling and hunting centre, and it has a racecourse.

MALLOW, any plant of the family Malvaceae, especially of the genera *Hibiscus* and *Malva*, the latter embracing about 30 species of annual and perennial herbs, widely distributed throughout the northern hemisphere, some of which are cultivated in the

garden. The mallows possess the kidney-shaped one-celled anthers that characterize the Malvaceae (q.v.). The petals also are united by their base to the tube formed by the coalesced filaments of the stamens. The special characters that separate the genus *Malva* from others most nearly allied to it are the involucre, consisting of a row of three separate bracts attached to the lower part of the true calyx, and the numerous single-seeded carpels disposed in a circle around a central axis, from which they become detached when ripe. The flowers are mostly white or pinkish, never yellow, the leaves radiate-veined and more or less lobed or cut.

The common mallow (*Malva sylvestris*), the *mauve* of the French, is an erect biennial or perennial plant with long-stalked roundish-angular serrate leaves, and conspicuously axillary reddish-purple flowers, blossoming from May to September. Like most plants of the order it abounds in mucilage, and hence forms a favourite domestic remedy for colds and sore throats. The aniline dye called mauve derives its name from its resemblance to the colour of this plant. Besides the foregoing, three other species have become naturalized in various parts of North America.

Three species are found in Britain. The musk mallow (*Malva moschata*) is a perennial herb with five-partite, deeply cut leaves and large rose-coloured flowers clustered together at the ends of the branched stems and is found growing along hedges and borders of fields, blossoming in July and August. It owes its name to a slight musky odour diffused by the plant in warm dry weather when it is kept in a confined situation. The round-leaved dwarf mallow (*Malva neglecta*) is a creeping perennial growing in waste sandy places, with roundish serrate leaves and small pinkish-white flowers produced in the axils of the leaves from June to September. It is common throughout Europe and the north of Africa, extending to western and northern Asia.

The marsh mallow (*Althaea officinalis*), the *guimauve* of the French, belongs to the same genus as the hollyhock (q.v.). (For rose mallow, see *HIBISCUS*.) The mallow of Scriptures (Job xxx, 4) has sometimes been identified with Jew's mallow (*Cochlospermum olitorius*), a member of the allied family Tiliaceae, but more plausibly with *Atriplex halimus*, the sea orache of Europe. Once widely used in medicine, mallows are no longer considered of value.

MALMEDY, a small town acquired by Belgium from Germany through the treaty of Versailles, 1919. It lies in a deep basin on the Warche, 20 mi. S. of Aachen, Federal Republic of Germany by rail via Eupen. See EUPEN-ET-MALMEDY.

MALMESBURY, JAMES HOWARD HARRIS, 3rd EARL OF (1807-1889), English statesman, was born on March 25, 1807, in London, and educated at Eton and at Oriel college, Oxford. Member of parliament for Wilton in 1841, when he succeeded to the title. Malmesbury first became prominent after the Conservative split over the corn laws in 1846. He was a staunch old-fashioned Tory and active supporter of Lord Stanley, later Lord Derby, under whom he served as foreign secretary in 1852 and 1858-59. Despite his lack of experience, Malmesbury, who was naturally pacific and dubious of Palmerstonian methods, proved adequate to a difficult task. Francophile through inclination and his acquaintance with Napoleon III, he concentrated upon improving Anglo-French relations. He was the first to recognize the establishment of the Second Empire; over the Italian question he attempted, with little success, to combine neutrality, tempered by a preference for the Habsburg position, with benevolence toward France. Though never holding executive office again, Malmesbury remained a respected and influential figure in Conservative circles. From 1866 to 1868 and from 1874 to 1876, he was lord privy seal; he died on May 17, 1889, at Heron Court, Hampshire.

Malmesbury's political career owed much to his friendship with

FROM GROOM, "ELEMENTARY BOTANY" (6. ILL. AND SOHS)

VERTICAL SECTION OF COMMON MALLOW (MALVA SYLVESTRIS) FLOWER

Derby, and to the paucity of talent in his party after the secession of the Peelites. Cosmopolitan in his tastes and connections, his extensive if casual knowledge of European problems and personalities was his main qualification for the foreign office, although his performance there surprised the critics. In 1884 he published his *Memoirs of an Ex-Minister*, a valuable source for a crucial period in the history of the Conservative party. (A. F. T.)

MALMESBURY, a market town and municipal borough (1885) of Wiltshire, Eng., 22 mi. N.E. of Bath by road, stands on a ridge between the Salisbury Avon and its tributary, the Inglesbourne. Pop. (1961) 2,610. Maildulf or Maeldulf, a Scottish or Irish monk, built a hermitage near the site of the modern Malmesbury about 635. This formed the nucleus of the later abbey, of which Aldhelm, his pupil, became the first abbot. Aethelstan, who was buried there, rebuilt and endowed the monastery, and there William of Malmesbury (q.v.) was brought up from childhood. A Benedictine abbey church was built on this site in the 12th century and part of it, restored in 1928 by Sir Harold Brakspear, is now the parish church. The nave is transitional Norman and Decorated and the south porch is Norman. At the time of the Dissolution, the abbey and its lands were bought by a rich clothier. The abbey church was fitted with looms for weaving, and later presented to the townspeople to replace their decaying parish church. All that remains of the latter is the tower which contains the town clock and the abbey bells. In the market square stands a fine market cross of the 16th century, borne upon an octagonal battlemented basement. The 13th-century hospital of St. John of Jerusalem survives as fragments in a corporation almshouse.

The town grew up round the abbey and at the time of the Domesday survey it was one of the only two boroughs in Wiltshire. The building of a castle by Henry I (pulled down in the 13th century) gave further impetus to the growth of the town. Following earlier charters, the first charter of incorporation was granted in 1635. The borough returned two members to parliament from 1295 to 1832 and one member from then until 1885. Thomas Hobbes, the philosopher, was born in Malmesbury in 1588. From the middle ages to the 1750s the town possessed a considerable cloth manufacture, and silk industries flourished during the 19th century. It now has an agricultural trade and firms making electronic, radar and striplighting equipment.

The churchyard at Garsdon village, 2 mi. E., contains the graves of some of George Washington's ancestors.

MALMÖ, a seaport and industrial city of Sweden, capital of the *län* (county) of Malmöhus, is located on the Sound, 26 km. (16 mi.) E.S.E. of Copenhagen, Den. Pop. (1960) 228,878. In Stortorget, in the centre of the city, stands the town hall, the oldest parts of which date back to 1546. Nearby is the residence of the provincial governor, originally built in 1730. Stortorget also contains an equestrian statue of Charles X Gustavus, who captured Skåne, Halland and Blekinge (the southernmost part of Sweden) from Denmark. The old main street of the town, lined with historic buildings, leads to the Malmöhus, a 16th-century castle and fortress, now a museum. St. Peter's, Malmö's oldest church, dates from the early 14th century and is a beautiful example of early Baltic Gothic. Malmö has a modern municipal theatre, opened in 1944, and one of Sweden's largest town libraries. Folkets park is the oldest amusement park in the country. During the 1950s and early 1960s considerable building was done in Malmö, chiefly of blocks of flats.

Malmö is an important traffic junction. From it, trunk rail lines lead to Stockholm, Göteborg and, via train ferry from Trelleborg, to the rest of Europe. There is a lively passenger traffic between Malmö and Copenhagen by boat and ferry across the Sound. The city has a busy harbour with a free port. Chief imports include coal, fuel oil, metals and chemicals; principal exports are grain, fodder, sugar, cement and clay. There is an international airport at Bulltofta. The city has a diversified industry including shipbuilding, manufacture of rail freight cars, textiles, clothing and cement, and food processing.

The name "Malmö," derived from *malm*, "sand," and *högar*, "hills," is mentioned in the 12th century. During the late middle ages the city was an important centre of the herring fishery, and

it experienced a period of greatness during the 16th century, when it played an important part in northern European politics and in the Reformation. It suffered an economic decline following its union with Sweden in 1658. With the building of the harbour in 1775 its fortunes revived, and from the middle of the 19th century it developed rapidly as an industrial and transportation centre. (L. L.J.)

MALMÖHUS, the southernmost *län* (county) of Sweden, which, with Copenhagen (Den.), controls the Sound. Area 4,865 sq.km. (1,878 sq.mi.). Pop. (1960) 625,667. It extends for 108 km. (67 mi.) north-south and 90 km. (56 mi.) east-west. Faulting has produced a gentle relief, trending northwest-southeast; the highest point is Kläggerödshöjden (610 ft.). The fault-formed coast has few harbours. The only Swedish coal field is behind Hälsingborg, but the coal is poor. Malmöhus is the principal Swedish sugar-beet area. Industrial activity includes textile mills, cement works, shipbuilding, manufacture of margarine and brewing.

A ship canal traverses the Faisterbo peninsula. Malmö (q.v.), a free port from 1922, is capital of the *län* and the third city of Sweden. Trelleborg is Sweden's southernmost port.

(A. C. O'D.)

MALNUTRITION. Maintenance of proper nutrition (q.v.) depends primarily on the provision of appropriate quantities of all the nutrients. Wrong proportions among these quantities result in a condition of malnutrition; an insufficient total amount of nutrients results in undernutrition, of which condition the extreme degree is starvation. Malnutrition also may be caused by impaired physiology as, for example, in certain diseases, even though the dietary intake may be adequate. Such malnutrition, usually called conditioned malnutrition, is a problem of clinical medicine and will not be discussed in this article.

Various meanings have been applied to the word malnutrition. While its literal meaning is "faulty or imperfect nutrition," the word is frequently used only to describe deficiencies. Malnutrition may also result, however, from excessive food intake. This is particularly evident in the case of excessive consumption of calories, but there is also reason to suppose that excessive consumption of carbohydrates and fats, quite apart from calories, may produce various forms of malnutrition. Obesity, the result of this type of unsatisfactory nutrition, is associated with much ill-health and in severe cases with a greatly increased mortality rate. In this review the word malnutrition will be used in its literal meaning and will be applied to conditions caused by deficiencies and excesses in the supplies of nutrients.

Detecting Malnutrition.—Various types of evidence indicate malnutrition. Presumptive or suggestive evidence includes vital statistics (growth rates, maternal mortality, infant mortality, etc.) and statistics of national available food supplies. Statistics, however, have many serious limitations as diagnostic evidence. Vital statistics, for example, reflect the collective effects of disease, environment and many factors of which nutrition is only one.

Indirect evidence must be supplemented by more specific information from nutrition surveys. The basic method is clinical appraisal combined with dietary surveys. Simple laboratory tests may usefully supplement the basic method. Clinical assessment includes a general inspection and a detailed inspection. The former includes the appearance of health, intelligence and vitality or their opposites conveyed to the mind of the examiner. The detailed examination includes inspection of the eyes, skin, mucous membranes, bones and subcutaneous deposits of fat. These body areas are those most likely to manifest evidences of undernutrition, deficiency disease and obesity.

DISORDERS OF MALNUTRITION

Nutrition surveys have revealed alarming evidence of malnutrition, the problems varying in different parts of the world. In underdeveloped areas the deficiencies, such as undernutrition, protein malnutrition, anemia, nutritional disorders of the eye and beriberi, are predominant. In regions in which food supplies are abundant and economic levels high, overnutrition is the main problem.

DEFICIENCY STATES

A nutritional deficiency may be caused by anything that diminishes the availability of a nutrient or nutrients to the tissues. Thus, although adequate amounts may be eaten, there may be a failure of the body tissues to absorb nutrients, or over-rapid excretion may occur. Deficiency states are frequently multiple, hence the clinical picture is often complex.

General Undernutrition or Chronic Partial Starvation.

—In places where, or in times when, food is scarce, cases of starvation occur because of insufficiency but not entire lack of food. Diets are predominantly rich in carbohydrates and deficient in most of the other nutrients. Further, coarse and unfamiliar food may be eaten, causing indigestion and diarrhea. The clinical symptoms presented by the afflicted vary with the nature of the food available. The commonest disturbances are low basal metabolic rate, slow pulse, lowered blood pressure, suppression of menses in women, dry, coarse, cold skin, bloodshot eyes, insomnia and fractures from osteoporotic changes in the bones. Nutritional edema, burning sensations in the feet and hands and sore mouth with increased salivation are common symptoms in chronic starvation. Classification of the possible degrees of undernutrition is given in the table.

Degrees of Undernutrition

State of undernutrition	Weight loss (% underweight)	Effect on functions and characteristics
Slight . . .	10	No serious functional deterioration
Moderate . .	10-20	Substantial change, but condition often compatible with light or moderate work
Severe . . .	20-30	Profound changes—may be able to do light work but condition is potentially serious
Extreme . .	more than 30	Patient grossly abnormal—rarely capable of any useful work
Very extreme	50	Severe and often fatal

The simplest way of treating starvation is to get the patient to take easily digested, highly nutritious food. The first to be given should be skimmed milk and well-strained vegetable and meat soups; glucose should be added to the milk. As soon as the patient is able to digest these, the diet can be gradually expanded to include whole milk, lean meat, fish, vegetables and fruits.

Protein Malnutrition.—Protein deficiency is widespread in many parts of the world, particularly in the tropics. Kwashiorkor, a form of protein malnutrition commonly occurring in infants and young children who have been fed on a diet low in protein and composed mainly of foods rich in carbohydrates, has been recognized in many parts of the world, particularly in Africa, India, Indonesia, southeast Asia and Central and Latin America. The main characteristics are retarded growth and development, apathy and anorexia, edema, pellagroid skin lesions, alterations in skin and hair pigmentation, fatty liver and diarrhea. There may be signs of associated vitamin deficiency.

Protein malnutrition is found in a continuous range from the classical forms in which calories are adequate, even abundant, to those in which there have been a severe calorie deficit and considerable wasting. The latter type is often called marasmic kwashiorkor.

Treatment of patients suffering from protein malnutrition is essentially dietetic. The protein-rich diet may consist of a mixture of powdered skim milk and suitable forms of carbohydrate such as ripe bananas. As soon as the digestive function will permit, return should be made to a well-balanced normal diet suitable for the child's age, since milk alone will not satisfy calorie and other requirements. In areas where kwashiorkor is prevalent a long time would be required before adequate supplies of animal protein could be provided; hence, attention is focused upon improving the quality of protein of vegetable origin, as from soybeans, peanuts and legumes.

Nutrition and Anemia.—Anemia constitutes a public health problem of great magnitude, particularly in the underdeveloped and tropical areas of the world. Malnutrition underlies most of the anemias in these areas, affecting particularly expectant and nursing mothers, infants and young children. Deficiency anemias are classified as (1) deficiency in nutrients (iron and protein)

necessary for the formation of hemoglobin (nutritional deficiency anemia); and (2) deficiency in such substances as folic acid and vitamin B₁₂, necessary for red cell formation. (See ANEMIA.)

Nutritional Deficiency Anemia.—The symptoms may be vague or concrete. The patient may complain only of unusual fatigue or a feeling that he is "run down." Nausea and vomiting, laboured breathing, headache and dizziness may develop after the anemia has continued for some time. The number of red cells may be low or near normal, but they are pale and small; the hemoglobin concentration is low. Anemia is corrected by supplements of iron, given as ferrous sulfate.

Pernicious Anemia.—This disease, due to a deficiency of vitamin B₁₂, usually occurs after the age of 40. Numbness and tingling of the hands, yellowing of the skin and a burning sensation in the mouth are the first signs. Diarrhea, loss of appetite, loss of weight and weakness also are common complaints. Later the patient begins to suffer from shortness of breath. Eventually, if given no treatment, the patient becomes exhausted and finally comatose. There is a marked decrease in the red blood cell count, and a number of immature blood cells appear in the blood. Other characteristic symptoms include a decrease in the hydrochloric acid of the stomach and disturbances of the central nervous system. An unexplained phenomenon is the periods of remission during which the patient becomes almost symptom-free. The diet for pernicious anemia is a normal diet that contributes to the patient's general nutrition, supplemented by vitamin B₁₂.

Vitamin A Deficiency.—Clinical signs and symptoms include night blindness, xerophthalmia (producing dry, dull eyeballs), softening of the cornea and dermatosis characterized by eruptive lesions of the hair follicles with keratinization. Each of these manifestations may occur alone or in combination with other signs and symptoms. Treatment is with daily supplements of vitamin A, which causes prompt regression of night blindness and xerophthalmia.

Riboflavin Deficiency.—This deficiency is prevalent throughout practically all the underdeveloped world, especially among infants and children in areas where other deficiency diseases are endemic. Manifestation of this deficiency involves the eyes, lips and skin. There is vascularization of the cornea, circumcorneal infection and, later, development of opacities. Angular lesions on the lips at the corners of the mouth (cheilosis) appear. The lesion of the skin is of the seborrheic type with flaking and greasiness over a reddened base. Milk and organ meats, the rich natural sources of riboflavin, should be prescribed but other water-soluble vitamins should be given as well.

Beriberi.—This is a chronic disease endemic among people who subsist almost entirely on polished rice. Though it may be due to multiple deficiencies, the most important is that of vitamin B₁ (thiamine). Three types of beriberi have been described: (1) dry, characterized by multiple peripheral neuritis with muscular atrophy; (2) wet, where edema is present; and (3) cardiac or acute, with cardiovascular changes. Manifestations of thiamine deficiency are loss of appetite, nausea, gastrointestinal disturbances, degenerative changes in heart muscle and multiple neuritis. Treatment consists in supplying thiamine daily by mouth or injection. (See BERIBERI.)

Pellagra.—This chronic disease due to deficiency of niacin is found principally among maize-eating populations, who are particularly predisposed because the principal protein of maize, zein, lacks tryptophan, an amino acid the body can convert into niacin. The symptoms characteristically involve the skin, the gastrointestinal tract and the nervous system, forming the classical clinical triad of dermatitis, diarrhea and dementia. The skin lesions tend to appear bilaterally symmetrically on the areas of the body exposed to sunlight. Treatment consists in giving niacin daily in divided doses with supplements of yeast, liver by injection and thiamine and riboflavin to combat the deficiency of the other B vitamins. (See PELLAGRA.)

Other Deficiency Diseases.—The occurrence of other deficiency diseases is now relatively uncommon. These include scurvy, due to a lack of vitamin C (ascorbic acid); rickets (q.v.), a manifestation of vitamin D deficiency; goitre, due to iodine de-

ciency; and hypovitaminosis K, which accounts for the occurrence of hemorrhagic disease of the newborn.

See also VITAMINS.

OVERNUTRITION

In most of the highly developed countries of the west, overweight in adults probably represents the commonest form of malnutrition. The prevalence of overweight and obesity is accompanied by increased mortality from a number of degenerative diseases, one of which is arteriosclerosis, a leading cause of death in many technically developed and well-fed countries (see ARTERIES, DISEASES OF).

The exact point at which obesity begins is difficult to define, but as a general rule a person is considered obese when the body weight increases by 20% above the average weight of healthy persons aged 25 and of the same height. This average weight at age 25 is termed desirable weight.

The immediate cause of obesity is the consumption of food providing calories in excess of energy requirements. However, there are multiple remote causes related to factors that cause an inappropriately positive calorie balance and eventually an inappropriately high body lipid content. The possible roles of genetic factors, hypothalamic lesions, hormonal disturbances and increased peripheral glucose utilization, which have afforded a means of study of obesity in experimental animals, do not seem to apply broadly in explaining the pathogenesis of obesity in man; obesity is generally regarded as a psychosomatic disorder of multiple cause featuring a disturbance in the mechanism that matches food intake to energy expenditure.

The most useful treatment for obesity is diet therapy—a reducing diet that should supply an intake of calories substantially less than an obese person's customary food intake (1,000 to 1,200 cal. per day) but that should contain at the same time adequate quantities of protein and the various nutrients. Exercise increases the energy requirement and stimulates basal metabolism and is, therefore a special factor in the management of obesity. The psychological aspect is also particularly important; the pleasure of eating usually influences greatly the desire for food and may be seized upon to replace other satisfactions of living. An effort must be made to discover the cause of a person's emotional disturbance before demanding his co-operation in a reducing diet. Some substitute for the satisfaction obtained from food must be found.

CAUSES AND PREVENTION

There are a number of distinct causes of malnutrition, most of which are interrelated. The fundamental causes include agriculture, economics and social and cultural factors.

Only about one-third of the population of the world has an adequate available food supply. The areas in which deficiency diseases predominate are technically underdeveloped and agricultural yields are low. In certain countries the amount of arable land available per head of population is small. Where the population is dense, pressure on land available for cultivation is high. In many cases the growth of the population is outstripping the supply of food that can be produced at existing levels of agricultural development. In areas where such conditions obtain, the population must depend on consumption of direct products of the soil. Land must be devoted largely to such major staples as rice, maize, cassava, millets and wheat that give a high calorie yield per unit of area. Green and leafy vegetables, for example, are important "protective" foods, yet the calorie yield per acre is so low in comparison to that of the major staples that many parts of the world cannot afford to grow them.

Throughout the underdeveloped parts of the world, therefore, the diets of the people contain a predominance of cereals or tubers or both. Other foods, and particularly foods of animal origin, are included in the diet in relatively small amounts. Diets that contain so high a proportion of cereal are inevitably deficient in terms of modern standards of nutrient requirements, thus leading to malnutrition. Typically, adults seem to survive quite well on these predominantly cereal diets; it is among the more vulnerable groups—infants, preschool children, pregnant and nursing

women—that malnutrition first appears. Improvement in agricultural practices, in varieties of crops, in storage practices, in transportation and marketing arrangements are fundamental to prevention of malnutrition in these areas of the world.

Moreover, people in these areas usually depend for their existence almost entirely on agriculture in the broad sense of this term; industry on a large scale has not been developed. Economic levels, therefore, are low and people cannot afford to buy foods to supplement the staple cereal. Families that purchase their food must spend a high proportion of the family income—often 70% or more—in obtaining their present meagre and ill-balanced diet. Until their economic condition is improved, such families cannot afford to buy supplementary foods in sufficient quantity even when they are available. Another way in which poverty influences diet is in forcing small producers to sell more expensive protective foods of which they are themselves in need in order to be able to buy the staple foods and other essentials.

With poverty go illiteracy and ignorance, and in such circumstances the improvement of food habits through education is difficult. Social systems have important effects on food habits and nutritional problems. For example, it is common to find a system of priority within families that gives the father the first choice of available food; the mother comes second and the children last. Food taboos, unsound food beliefs and food practices are encountered: there are groups who have eggs but will not eat them, regarding egg eating as a sign of greed; the main and cheapest source of animal protein in some areas, dried fish, may be thought to cause worms and "bad eyes"; there are groups who believe that cow's milk is not a proper food for children; and in some communities the taking of milk by girls and especially by married women has powerful emotional connotations. Food habits also are affected by religion.

While awaiting the slow improvement in agriculture and economy, malnutrition can be alleviated by nutrition education. The fundamental aim of nutrition education should be to improve utilization of existing resources. Teaching and practical demonstration should aim at countering food taboos; increasing local production of food, use of appropriate methods of preserving foods, and selection of well-balanced low-cost diets composed of locally available foods; introducing methods for the preparation of food based upon good hygiene and sound nutritional principles; and preparing correct diets for infants and young children.

The predominantly cereal diets of many areas of the world also can be improved by enrichment with certain vitamins, minerals and certain amino acids such as lysine. In the past this was not feasible economically, but improvements in the production of many synthetic nutrients now make it possible. Thus, the protein of wheat and rice can be substantially improved by the addition of lysine, giving great promise for future decrease in protein malnutrition.

MALOLOS, a municipality, capital of Bulacan province on Luzon Island, Phil., lies on a flat, poorly drained plain, about 20 mi. N.W. of Manila. During the revolution against the U.S. the insurgent congress met there and framed the "Malolos constitution," by virtue of which the constitutional Philippine republic was proclaimed on Jan. 23, 1899. The insurgent leader, Emilio Aguinaldo, established his headquarters in Malolos and it served as the insurgent capital until it was captured by U.S. forces in March 1899.

Malolos is an important trading centre in a heavy rice- and vegetable-producing region. Major fish-pond areas are located south and west of the administrative centre.

The municipality lies astride the main highway leading north

through the central plain northward from Manila and is also bisected by the rail line to the Lingayen gulf. Pop. (1960) 48,968. (R. E. HE.)

MALONE, EDMOND (1741–1812), Irish Shakespearean scholar and editor, a pioneer in the establishment of an authentic text and chronography of Shakespeare's works, was born in Dublin on Oct. 4, 1741. The son of a barrister, he was educated at a private school, at Trinity college, Dublin, and at the Inner Temple, which he entered in 1763. After visiting France and working in Ireland as lawyer and journalist, he settled in London in 1777. There his friends included Samuel Johnson, Sir Joshua Reynolds, whose works he collected and published (1797), Horace Walpole, Edmund Burke, George Canning and George Stevens. He helped James Boswell to revise the *Life of Samuel Johnson*, of which he himself edited and annotated four reissues.

Malone's "Attempt to ascertain the Order in which the Plays of Shakespeare were written" (1778) and his three supplemental volumes (1780–83) to the Johnson-Stevens edition of Shakespeare, containing the poems, apocryphal plays, additional notes and textual emendations, are landmarks in Shakespeare studies. His essay on the history of the Elizabethan stage was the first authoritative treatise on English drama. His own edition of Shakespeare, in 11 volumes, appeared in 1790. At the time of his death on April 25, 1812, he was working on a new octavo edition which was completed by James Boswell, son of the biographer, and published in 21 volumes, with a memoir of Malone, in 1821. Known as the *Third Variorum*, or "Boswell's Malone," it remained for over a century the standard complete edition. Although unimaginative in aesthetic criticism, Malone was immensely industrious and learned. His scrupulous scholarship is attested to by his edition of Dryden's prose works (1800), as well as by his work on Shakespeare. The zeal for truth displayed in his editing showed itself also in his denunciation (1782) of the Chatterton "Rowley" poems and (1796) of the Ireland Shakespeare forgeries (see CHATTERTON, THOMAS; IRELAND, WILLIAM HENRY).

See Sir James Prior, *Life of Edmond Malone* (1860). (Jo. C.)

MALONIC ACID crystallizes in large colourless plates, dissolving readily in water, alcohol or ether, and melts at 135.6° C. Although the sparingly soluble calcium malonate occurs in beetroot, the acid itself, $\text{HO}_2\text{C}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, is generally produced by laboratory methods, such as the oxidation of malic acid or the hydrolysis of cyanoacetic acid, $\text{CN}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$. When carefully heated at 140°–150° C., malonic acid partly decomposes into acetic acid and water, but 10%–12% undergoes dehydration with formation of carbon suboxide, C_3O_2 .

The outstanding importance of malonic acid in systematic chemistry arises from the varied syntheses which can be effected with its ethyl ester, diethyl malonate, commonly called malonic ester, $\text{CH}_2(\text{CO}_2\text{C}_2\text{H}_5)_2$. This ester, usually prepared by passing hydrogen chloride into a solution of cyanoacetic acid (obtained from chloroacetic acid) in absolute alcohol, is a colourless fragrant liquid boiling at 198° C. Its very reactive methylene group, CH_2 , is instrumental in effecting syntheses of higher mono- and dibasic acids. The replacement of one hydrogen of this methylene group by sodium gives sodiomalonic ester; this on treatment with an alkyl iodide gives the ester of the corresponding alkyl malonic acid. In the presence of sodium ethoxide the esters of malonic acid and diethylmalonic acid undergo condensation with urea to furnish respectively barbituric and diethylbarbituric acids, the latter being the well-known soporific drug veronal (see BARBITURATES). By a similar condensation with urea ethylphenylmalonic ester yields the drug phenobarbital.

MALORY, SIR THOMAS (d. 1471), English writer, author of the book known as *Morte Darthur*, the best-known prose account of the rise and fall of King Arthur and the fellowship of the Round Table, and the first in modern English. Even in the 16th century the identity of Malory was unknown, although a tradition associating his name with Maelor (a district in the county of Flint), and thus crediting him with Welsh connections, has persisted since the time of John Bale (1495–1563). In 1894 George L. Kittredge suggested that he was in fact Thomas Malory, knight, of Newbold Revell, in the parish of Monks Kirby, War-

wickshire. Subsequent research has amply confirmed this hypothesis. According to Sir William Dugdale (1605–86), Malory of Newbold Revell served in the train of Richard Beauchamp, earl of Warwick, at Calais (presumably in 1436), was knight of the shire for Warwickshire in 1445 and died on March 14, 1471. The name Thomas Malory occurs in a list of knights who went with Edward IV on his expedition into Northumberland in Nov. 1462, and this may well be our Malory. Other reliable information from judicial records shows that he was accused of various offenses at different times, notably of a series of felonies (including rape, conspiracy to murder and armed assault on the Cistercian abbey of Coombe) in Warwickshire in 1450–51, horse stealing and planning to attack property in Essex in 1454. He was imprisoned on various occasions between 1451 and 1460 and committed to Newgate in 1460. In Aug. 1468 he was excluded from a general pardon. The colophon to William Caxton's edition of the *Morte Darthur* states that the book was "ended the ninth yere of the reygne of kyng edward the fourth [i.e., March 4, 1469–March 3, 1470] by syr Thomas Maleoré, knyght" and adds a prayer for "good deliverance" (from prison), while the Winchester manuscript discovered in 1934 contains several references to the author's imprisonment. The Malory family had several branches and at least one other Thomas Malory appears in contemporary records, but it seems hardly possible that the "knight prisoner" of the Winchester manuscript can be any other than the unfortunate gentleman from Newbold Revell. That an energetic and reckless individual, living in a lawless age, should commit deeds of violence and at the same time take pleasure in retelling tales of a warlike king and his bold companions does not seem in any way improbable.

The Morte Darthur.—Malory's book was printed by William Caxton, who named it the *Morte Darthur*, in 1485, and reprinted by Wynkyn de Worde in 1498. Until the discovery by W. F. Oakeshott in 1934 of a late 15th-century manuscript in the fellows' library at Winchester college, no other 15th-century form of the text was known. The Winchester manuscript contains a much longer, and obviously more authentic, version of book v than does Caxton; the other significant differences between the two texts occur in *incipits*, colophons and rubrics. The monumental critical edition by Eugène Vinaver (1947) is based on the Winchester manuscript.

Sources.—Book v of the *Morte Darthur* is an adaptation of a 14th-century English poem, the alliterative *Morte Arthure*. The rest of the work consists almost wholly of material from the 13th-century French Arthurian prose romances (see ARTHURIAN LEGEND). The narrative content of these is not fundamentally altered, but numerous changes in detail and Malory's free and vigorous stylistic treatment have produced a result much nearer to genuine creative writing than to translation. More than one-third of the work (books viii–xii) is taken up by Malory's translation of the first two-thirds of the prose *Tristan*. (See also *TRISTAN*.) This unwieldy work, an adventure romance containing a great wealth of incident and bringing in a whole host of characters, has no real connection with the story of Arthur, and does not fit into any consistent account of his reign. Leaving aside the prose *Tristan*, what remains is an account, in chronological sequence, of the great events of the Arthurian saga: the birth and early exploits of the king, the war with Rome, the coming of Galahad and the quest of the Holy Grail, Lancelot's adultery with Guinevere; the civil war that arises because of this, followed by the revolt of Mordred and the final battle on Salisbury plain in which Arthur receives his death wound. The source of book vii ("The Tale of Sir Gareth") is unknown, but it may have originated in a lost French romance which arose as a late offshoot of the prose *Tristan*. The main part of the *Morte Darthur* (books i–iv, xiii–xxi) consists of an adaptation of the other great prose romances, the "Vulgate cycle" and the "post-Vulgate" romance—the fully developed series of prose romances covering all the Arthurian stories. The opening portion of the latter (the so-called "Huth Merlin") provides the subject matter of books i–iv, which recount the birth, youth, coronation and early adventures of Arthur. The Vulgate cycle of romances is represented by its two concluding branches: the *Queste del Saint Graal* and the *Mort Artu*, which form the substance of

books xiii-xvii and books xviii and xx-xxi respectively. The pathetic story of the maid of Astolat and the account of the great war between Lancelot and Arthur that breaks out after Agravain, Gawain's brother, has revealed the adultery of Lancelot and Guinevere to Arthur occur in the *Mort Artu* and are recounted fully by Malory. The third branch of the Vulgate cycle, which relates the courtship and early exploits of these two lovers, is given rather cavalier treatment. Book vi reproduces a few uninteresting adventures of Lancelot and book xix contains a grotesquely distorted form of the "knight in the cart story"; i.e., the account of Guinevere's abduction and her rescue by Lancelot. Otherwise, the third branch is completely neglected.

Treatment.—Malory's approach differs in some respects from that of his French models. Deeds of arms and martial valour, and the virtues (faithfulness, constancy and devotion to one's friends) normally associated with these, seem to have appealed to him particularly. For French courtly love, and the ingenious and often casuistical analysis of sentiment that went with it, he had little sympathy. The *Queste del Saint Graal* is faithfully translated and its ascetic outlook is well preserved, but the distinctive doctrinal content of the work has suffered from Malory's tendency to abridge or omit the sermons and exhortations which bulked so large in the original. His own additions show that he failed to sympathize with the challenge that it offered to the ideals of romantic chivalry. The episode of Sir Urré, whom Lancelot heals of his wounds when all others have failed (book xix), seems like an invention of Malory's own, designed to restore the balance between Galahad and Lancelot by making the latter's career culminate in a miracle of healing which turns him and the Round Table into a special channel of God's grace. It is not surprising that an author at once more emotional and more simple-minded than the French writers should be especially attracted to the *Mort Artu*, the most successful branch of the Vulgate cycle, in which the fall of Arthur is preceded by a clash of elemental loyalties. Malory, for whom mutual trust and devotion were the highest virtues and the Round Table a real and living brotherhood, exploited fully the tragic implications of the theme and, aided by suggestions from the stanzaic *Le Morte Arthur*, gave it a strong lyrical quality. In Malory's version the characters are caught up in a web of obligations that are repugnant to the deepest instincts of their nature. When Guinevere's adultery is discovered, and Arthur clearly sees that Lancelot is now against him, the fellowship of the Round Table is destroyed. Gareth, who loves Lancelot 'of all men earthly,' obeys Arthur's command to conduct the queen to execution with the greatest reluctance; when Lancelot rescues Guinevere, Gareth is slain and his brother Gawain, Lancelot's closest companion-in-arms, has to take vengeance. As a result the great civil war that "dispeoples" the Round Table begins, but all that Lancelot does is done in sorrow and not in anger. The treachery of Mordred and the death of Arthur form a mere appendix to this tale of strife. The great concluding speeches, on the other hand, ending with the threnody of Ector over the dead Lancelot, have a passionate intensity that raises Malory to the first place among the authors of his century.

Achievement.—In Caxton's edition the *Morte Darthur* is treated as a continuous work and divided into books and chapters. The Winchester manuscript divides it into a series of self-contained tales, each with its own explicit. To underline the autonomous character of each story Vinaver abandoned Caxton's spurious and misleading title and called his own edition *The Works of Sir Thomas Malory*. If, however, this new title implies that even the arrangement of the tales in the chronological sequence is not the work of Malory but the result of early editorial intervention, then it may itself be misleading. Nevertheless, it seems clear that Malory's work can be regarded as in some sense the end product of a process by which the early Arthurian prose-romances, with their multiplicity of ramifying and interwoven incidents, were transformed into a series of smaller works "each circumscribed within its own boundaries." It could therefore be maintained that, while Malory's book can obviously be treated as a chronicle of the Arthurian kingdom from its beginning to its close, it possesses no real artistic unity; rather it is the result of the

juxtaposition of elements that have the literary form of tales each complete within itself, in which the form, as well as the content, of each tale is determined by the character of the source of material. If this is the case, a fair assessment of Malory's achievement can be arrived at only by regarding each tale as a separate experiment in adaptation. It is perhaps therefore not altogether inappropriate that Caxton should have chosen for the whole book a name already familiar to English readers through earlier verse romances—a name which emphasizes the most significant episode in the Arthurian saga and which commemorates that portion of Malory's work which has earned him enduring fame.

MALPIGHI, MARCELLO (1628-1694), Italian physiologist, the founder of microscopic anatomy, was born on March 10, 1628, at Crevalcore near Bologna, where he graduated in medicine in 1653 and where he became lecturer in 1656. A few months later he was appointed to the chair of theoretical medicine at Pisa, but after four years he returned to Bologna. In 1662 he was appointed professor primarius at Messina. After a further four years he again returned to his native university, and spent the next 25 years there. In 1691 he moved to Rome as private physician to Innocent XII, and he died there on Nov. 30, 1694. Shortly before his death, he drew up a long account of his academic and scientific labours, correspondence and controversies, and committed it to the charge of the Royal Society of London, which published his autobiography in 1696.

Malpighi was one of the first to apply the microscope to the study of animal and vegetable structure, and his discoveries were of major importance. Although Harvey had correctly inferred the existence of the capillary circulation, he had never seen it; it was reserved for Malpighi in 1661 (four years after Harvey's death) to see for the first time the blood coursing through a network of small tubes on the surface of the lung and of the distended urinary bladder of the frog. This discovery was given to the world in two letters, *De pulmonibus*, published at Bologna in 1661 and often reprinted. These letters contained also the first account of the vesicular structure of the human lung, and they made a theory of respiration possible for the first time.

Malpighi's next achievement was a demonstration of the plan of structure of secreting glands. He maintained that the secretion was formed in terminal acini standing in open communication with the ducts. The name of Malpighi is still associated with his discovery of the mucous character of the lower stratum of the epidermis, of the vascular coils in the cortex of the kidney and of the follicular bodies in the spleen. He was the first to attempt the finer anatomy of the brain, and described the distribution of gray matter and of the fibre tracts in the cord, with their extensions to the cerebrum and cerebellum, with great accuracy, though from his microscopic study of the gray matter he concluded that it was of glandular structure and that it secreted the "vital spirits." At an early period he applied himself to vegetable histology, and became acquainted with the spiral vessels of plants in 1662. His *Anatomia plantarum*, published in 1672, included the *Observationes de ovo incubato*, which gave one of the best accounts (with good plates) of the development of the chick. His *Diss. epist. de bombyce* (1669) elaborately described the structure and metamorphosis of the silkworm.

Malpighi also wrote *Epistolae anatomicae Marc. Malpighii et Car. Fracassati* (1662), on the tongue, brain, skin, omentum, etc.; *De viscerum structura: exercitatio anatomica* (1669); *De structura glandularum conglobatarum* (1689). *Opera posthuma, et vita a seipso scripta* (1697) with preface and additions was published at Amsterdam in 1700. An edition containing all his works except the last two was published in London in 1686.

See Logan Clendening, *Source Book of Medical History*, pp. 209-217 (1942).

MALPLAQUET, BATTLE OF (1709), a marginal victory near Malplaquet, a village 10 mi. S.W. of Mons in Hainaut (now on the French side of the Franco-Belgian frontier), by British forces under the duke of Marlborough and the Holy Roman emperor's forces under Prince Eugene of Savoy against French forces under Marshal de Villars and Marshal de Bouffiers, on Sept. 11, 1709, during the War of the Spanish Succession (q.v.).

Proposed Anglo-imperial siege operations against the fortress of Mons were being threatened by a revitalized French army, about 90,000 strong, which moved to pass the natural wooded barrier separating it from Marlborough's army (also about 90,000) through the gap at Malplaquet. The operation was checked by Marlborough and both sides waited: the allies for reinforcements, and the French to fortify their naturally strong position.

Marlborough decided to attack the defended woodlands on either side of the gap, the heaviest blow to be delivered against the forest of Taisnière, north of Malplaquet on his right. Should the centre be weakened by these flank attacks, he intended to surge through it as he had at Blenheim (q.v.). These tactics were employed and were eventually successful. Each step toward victory, however, was bitterly contested. Only with difficulty and after tree-to-tree fighting was the wood of Taisnière cleared. On the allied left the containing activity, allotted to John William Friso, prince of Orange, and his Hollanders developed into an unsuccessful major action costing between 7,000 and 8,000 Dutch lives. When the flank pressures allowed the infantry to take the entrenchments in the Malplaquet gap the allied cavalry passed through, but repeated well-conceived counterattacks by the French cavalry, while they did not stop the advance, did prevent a French rout. Indeed, it is possible that had not Villars been carried wounded from the field the French might have at least held their ground. As it was, Bouffiers conducted an orderly retreat and the allies were too exhausted to interfere with the withdrawal.

Strategically, the battle put an end to any idea the allies might have entertained of advancing on Paris, and it marked Villars as a general of stature. Tactically, it revealed, for the last time, the exceptional co-operation of Eugene and Marlborough in a pitched battle, and Marlborough's cool competence under difficult circumstances. Malplaquet was a battle worthy of particular note for its desperate and costly nature: the French lost about 11,000 men and the allies about 20,000. It was, as Marlborough wrote of it, "a very bloody battle." (D. M. Sc.)

MALRAUX, ANDRÉ (1901—), French writer and politician who, in all his writing—novels and studies of art—attempts "to give men a sense of the grandeur they fail to recognize in themselves." He was born in Paris on Nov. 3, 1901, of a well-to-do family, and showed an early interest in the arts and also a wish for a life of action and adventure. At the age of 21 he went to Indochina on an archaeological expedition. During this period, while he was excavating Khmer statues, he studied the problems of the colonial peoples and was involved in the activities of the Young Annam league. Later, he lived in Canton and Shanghai, saw the revolutionaries in action, probably worked with the Chinese Liberation movement and followed closely the work of the Kuomintang. On his way back to Europe, in 1927, he made important discoveries of Greco-Buddhist art in Afghanistan and Iran. He then flew over the Arabian desert and discovered what may have been the site of the queen of Sheba's legendary city. After his return he devoted himself to the fight against rising fascism, and participated in numerous anti-fascist activities. When the Spanish civil war broke out in 1936, he flew to Madrid and organized an international air corps for the Republicans. In 1939-40 he was an officer in the French regular army, was wounded and captured, escaped, was active in the *maquis*, was captured again, escaped and finished the war as an officer in Alsace. After the war he turned to politics and became one of the leaders of the Rassemblement du Peuple Français, the movement created by Gen. Charles de Gaulle. This failed, but when De Gaulle returned to power (1958) Malraux was appointed minister of cultural affairs in the first cabinet of the fifth republic.

Between the acts of this dramatic and absorbing life, Malraux who had never lost his interest in art and literature, wrote several brilliant, powerful books and rose quickly to an eminent position among modern writers. His first important novel, *Les Conquérants* (1928), described insurrection in Hong Kong and an adventurer, Garine, who wanted "to give a meaning to life." Most of Malraux's heroes are men of action: through them the author explores the meaning of life, the moral and human implications of the struggles of a tragic era. *La Voie royale* (1930) has an Indochinese background; it is a tale of action, adventure and violence, and of man's efforts to achieve human dignity.

Malraux's best-known work, perhaps his masterpiece, *La Condition humaine* (1933), won him the Prix Goncourt and made him known to readers all over the world. Its background is Shanghai, during the crushing by Chiang Kai-shek of his former Communist allies (1927). Malraux was in Shanghai in those troubled times and poured his own experience into the book. But this is not a reporter's album of vignettes. The novel is powerfully constructed round the theme of revolution and its impact on a few well-chosen, magnificently drawn individuals. All the heroes of the novels share both a tragic fate and a pathetic solitude. But, unlike Garine, some of them discover the brotherhood created by common action. *Le Temps du mépris* (1935), a shorter novel, tells a story of the underground resistance against the Nazis in Hitler's Germany. In the important preface, Malraux defines his conception of fiction, which is akin to that of Greek tragedy (man, the crowd, human destiny) and emphasizes the need to understand and use art to "attempt to give men a consciousness of their own hidden greatness." From his experience in the Spanish civil war Malraux constructed the masterly fresco *L'Espoir* (1937).

His last novel, *Les Noyers de l'Altenburg* (1943), part of the unfinished *La Lutte avec l'Ange*, is a passionate, anxious interrogation on the concept of man. Malraux believes that man is what he makes. Man overcomes his tragic fate by "giving a meaning to human adventure." Revolution, love, art are ways of bringing the world into subjection. Man's dignity lies in not refusing his own greatness.

After 1945 Malraux as a novelist remained silent. Most of his time was devoted to politics and the history and criticism of art. He wrote, as well as a study on Goya (*Saturne*, 1950), the outstanding *Les Voix du silence* (1951), which was acclaimed as among the most important of modern works, although the art historians made reservations on Malraux's accuracy. It is a brilliant, well-documented synthesis of the history of art in all countries, at all epochs, and also a philosophical meditation and an attempt to redefine men and civilizations through the world of art. Malraux's wide culture, original style and faith in man make *Les Voix du silence* an eloquent statement of man's fate and greatness through active creation: "Civilization is not sweetness, but consciousness and mastery of man." This work was continued in *La Métamorphose des Dieux*, vol. i (1957).

MALT is a food product prepared from cereal grain by allowing partial germination to modify the seeds' natural food substances. Except for wrinkling of the husk, malt has mostly the physical appearance of the grain from which it was prepared. Malt itself is seldom a constituent of human food. It is rather an extract or the result of an enzymatic digestion by malt that is found in "malted" foods. Hence the term is frequently but erroneously applied also to a concentrated sirupy aqueous extract of malt. The starch of malt is mellowed and more soluble than that of the original grain. Its protein has become partially hydrolyzed. The enzymes (q.v.) developed during the malting process are responsible for its industrial importance.

Any cereal grain may be converted to malt by germination but barley (q.v.) is the favoured grain and has been hybridized to improve its malting quality wherever it is grown. Rye, wheat

rice and, to an even lesser extent, corn are malted in some countries, usually as a result of tax complications or legal restrictions protecting native farm products.

Uses.—The largest bulk of malt is used in the manufacture of beer (see BREWING) and most of the extractives in beer are derived from malt. Hence the flavour of beer is predominantly the result of the malt from which it was made. From 30 to 50 lb. of malt are used to make a barrel of beer, depending upon its strength and the use of adjunct starches.

The next most important use of malt is in the production of distilled alcohol for both beverage and industrial purposes. It is used in this case almost entirely for its enzymatic ability and is hence specially prepared as a high-diastatic or distiller's malt. The diastase of malt converts starches, obtained from corn, potatoes or other economical sources, into sugars which are then fermented to alcohol and concentrated by distillation.

Distiller's malt is also used in the production by fermentation (q.v.) of other solvents such as acetone, butanol and other higher alcohols.

Malt extracts are either sirupy concentrates or dry powders resulting from the evaporation of strained mashings of malt and water, sometimes including added starchy materials. The malt contributes maltose (a sugar not as sweet as cane sugar), dextrins, soluble protein and vitamins, especially of the B complex, to these materials. The extracts are used to impart a "malted" flavour to confections and food mixtures. Many special baby foods are prepared in a similar manner. If milk is added before drying the resulting powder is the familiar malted milk. Frequently these products are made so as to retain diastatic activity and are offered as aids to digestion. Diastatically active malt extract is used by bakers to improve the fermentation of their dough, thereby influencing the texture of their products.

While malt contains enzymes other than those capable of hydrolyzing starch, it owes its importance primarily to this ability. Starch sizing applied in the processing of textiles may be removed by enzymatic solubilization utilizing a malt extract as the source of amylase.

Method of Manufacture.—Malt production is a controlled and limited germination initiated by adding moisture and arrested by removal of the moisture before the young plant grows out of the seed covering. Production thus depends upon the life processes inherent in a dormant seed. The first step after the barley has been cleaned and sorted as to kernel size is to steep it in water for about 24 hours until the kernel has absorbed from 40% to 45% moisture. This absorption awakens the embryo and causes the life processes to begin. The dampened grain is then moved to a germinating apparatus, which may be a revolving drum or a rectangular open tank equipped with slow-moving agitators. In the second half of the 20th century a few smaller establishments still spread the grain on a floor and turned it by shoveling.

In either system a means is devised to conduct cooled and moistened air through the mass of sprouting grain and a gentle method of moving the grains is provided so as to prevent matting of the roots. Carbon dioxide is thus removed along with heat developed during the process. Growth and modification of the starchy constituents of the original grain are controlled through manipulation of temperature and moisture within the "piece," as the batch of grain is called.

During germination, enzymes are activated particularly along the scutellum, a membrane separating the embryo, which is largely proteinaceous, from the endosperm or starchy portion of the kernel. These enzymes include cytase, phytase, amylases, phosphorylases, proteases and, in fact, all those which the embryo plant will use in breaking down the food material stored in the endosperm and building it into root and eventually stem structures. These enzymes permeate the endosperm, converting the contained starchy starch into a softer and more soluble form. Some of this starch is hydrolyzed to maltose and dextrose, which are phosphorylated and then pass through the scutellum where they are reconverted to starch in the rootlets that push out at the bottom of the kernel. An incipient stalk called the acrospire also grows upward from the embryo along the side of the kernel inside the hull and will

eventually erupt from the top of the kernel to become the above-ground structure of a normal plant if the process is allowed to continue.

Since it is the enzymes and the partially converted starch that are desired, rather than a new growing plant, the growth or germination is stopped in malting when the acrospire has grown to or slightly beyond three-quarters of the kernel length. During this time the rootlets have generally attained a length of about an inch and the endosperm has been rendered entirely mellow. This change may take from four to nine days depending upon the temperatures permitted and the use for which the malt is intended.

When the desired amount of modification has been attained the biological processes are stopped by the simple expedient of removing the moisture necessary to sustain them. This cutoff is accomplished in a kiln, the floors of which are perforated to permit an upward current of dry, heated air to dry the grain. There are many kiln designs and many ways of operating them to control the rate of moisture removal and the amount of heating that is given. Timing and heat intensity govern the amount of caramelization and other changes that are associated with the development of both flavour and colour. Additional flavours are often imparted by the character of the fire used. For example, malt intended for Scotch whisky is dried over a fire to which peat is added. The ensuing smoke is taken up by the malt.

Distiller's malts and others retaining highest enzymatic activity are kilned at low temperatures, around 120° F., to preserve as much of the biological ability as possible. Consequently such malts are pale in colour and have little flavouring value. Some kernels retain the ability to grow. Those malts that are to be used primarily for flavouring or colouring qualities are kilned at temperatures in excess of 200° F. and retain little enzyme action. Malt intended for both enzymatic and flavouring purposes is finished off at intermediate temperatures.

Historical.—The processes of malting, brewing and baking have been closely entwined for a longer period of time than is covered by recorded history. Each was well known and developed into a triple industry or special activity in Egypt at the time of the Pharaohs. Records left by all of the ancient agricultural civilizations indicate that these arts had developed long before. Consequently the origin is resigned to the realm of Egyptian mythology. Osiris, the god of light, health and agriculture, taught man to malt as a preliminary step to brewing an alcoholic beverage that might allow him to escape the woes of the world. Man simultaneously discovered the leavening power of fermenting beer.

Since the sprouting of grain and fermentation will occur even without man's guidance, it may be safely assumed that early man sampled and liked a fermenting watery supernatant that he found over stored grain that had become drenched by rains. By observation, many deductions, experiments and, no doubt, a few temporary illnesses he learned to control the process of malting. Except for more accurate understanding of the biochemical changes involved, which led to better control, and for mechanical improvements, the malting process and its related processes of brewing and baking have remained unchanged.

In the period around 3000 B.C. spelt, wheat and barley were thrashed and winnowed by hand labour and stored in granaries for subsequent use. The biblical story of Ruth is a familiar reference to this though much more detailed and earlier information is contained in pyramid findings and in the Egyptian *Book of the Dead*. To prepare malt from this grain it was spread upon a flat surface in a pile perhaps about knee high and watered liberally until rootlets began to appear—after about two days. Water would then be added only to keep the pile moist and the grain would be turned by wooden shovels to keep the pile from overheating. Exact elements of control are unknown but it is possible that traditional tests of biting, kernel flexibility, buoyancy and the like may have had their origin this far back.

The first processes probably utilized green or undried malt for further processing, and earliest attempts at drying must have included spreading in relatively thin layers in the sun. Certainly the arid climate of Egypt at least contributed to very early adoption of dry air currents. Throughout ancient history and into the

middle ages few changes in even the methods of manipulation occurred. The European monasteries and the princely households continued to malt the available grain and, with the necessity of using heated kilns to dry the product in colder and more humid environments, the control of flavour was introduced.

As in other arts, control did not really improve until adequate means of measuring conditions developed. Uniformly scaled thermometers were introduced in the early 18th century. Other instruments followed and were adopted by the maltster-brewers. Barley became the favoured grain to malt and was ruled the only permissible grain for beer in Hamburg in the 12th century.

Not until 1873 was a satisfactory substitute for the hand labour of floor malting devised. In that year Nicholas Galland introduced a mechanical system termed the pneumatic method. While power-driven machinery had been put to use in many other industries before this, even including other brewery operations, no device had been gentle enough to both agitate and protect the grain during its germinating. Galland provided a rectangular compartment having a perforated false bottom that would allow passage of water or air but not of grain. A series of revolving augers reached into the grain to turn it as a rope drive supplied power which also enabled the entire agitator assembly to traverse the length of the compartment on a rack-and-pinion arrangement.

Shortly thereafter the rotating-drum system was introduced. From that time on further improvements were rapidly adopted; electric power, controlled speeds, oil- and gas-fired kilns, artificial refrigeration and volume handling were among the major innovations. None of these have, however, contributed new biological processes. The methods but not the process changed.

These improvements have altered the complexion of the industry substantially. At one time every brewer malted his own grain. Now the greater number of them buy malt from large separate maltsters, although a few of the larger breweries continue to malt much of their own requirements. This specialization has led to expansion in the use of malt for other purposes, to the more economical accomplishment of the changes, to the establishment of research laboratories devoted solely to malting problems and to greater support for barley-improvement programs of benefit to the barley growers.

MALTA (anc. MELITA). The Maltese Islands are situated between Europe and Africa, in the central channel which connects the eastern and western basins of the Mediterranean sea. The group is a parliamentary state, a member of the Commonwealth of Nations, and the site of a strategic British base. It consists of Malta (95 sq.mi.), Gozo (*q.v.*; 26 sq.mi.), Comino (1 sq.mi.) and the uninhabited rocks Cominotto and Filfla. Malta itself is about 60 mi. from the nearest point of Sicily, 140 mi. from the mainland of Europe and 180 mi. from Africa. Malta is about 17 mi. long by 9 mi. wide; Gozo is 9 by 4½ mi.; and the archipelago extends more than 29 mi. from northwest to southeast.

PHYSICAL GEOGRAPHY

A fairly narrow submarine ridge extends southward from Sicily toward Malta, and thence continues southwestward on a broader scale toward Tunisia and Tripolitania. This ridge, lying at 50 fathoms in its northern part and deeper to the south, is a sunken land bridge which appears to have connected Europe and Africa during epochs of the later Tertiary and Pleistocene. Malta has abundant fossil evidence of this early interconnection, particularly in certain of the cave deposits.

The main island consists of a fractured and warped plateau, composed of Miocene rock series with a few superficial deposits of Pleistocene age. The higher parts, of somewhat irregular shape, occur mainly in the west central area and to some extent in the north; these are either residual features produced by erosion or

ridges defined by fault scarps. The greatest height is 845 ft., in the irregular upland between Mdina (*q.v.*) and the southwestern coast. Thus, though small, Malta exhibits some variety in landscape and environment.

Structurally, the island can be regarded as made up of two somewhat differing component parts: the north, and the centre and south. The north is a region of horsts and downthrow zones controlled by imposing faults that mostly run from east-northeast to west-southwest. Downthrow is usually of the order of 200-400 ft., but the Victoria Lines fault, which runs across the island from Maddalena tower to Fromm ir Rih, appears to have nearly double this amount of displacement. Several nearly parallel horsts and ridges are discernible, separated by narrow lowlands, successively from the extreme north at Marfa, Mellieha, Bajda and Wardiya. Central and southern Malta consists of a shallow but complex anticline, aligned north-south. Faulting also occurs, but far less extensively than in the north.

Five rock series are usually distinguished. In order of formation they are Lower Coralline Limestone (the oldest), Globigerina Limestone, Blue Clay, Greensand and Upper Coralline Limestone. The Lower Coralline Limestone is a gray and relatively resistant formation which is exposed chiefly in a narrow coastal band in the extreme southwest, where it gives rise to a succession of imposing cliffs 200-400 ft. high; other exposures occur in the east-round Maddalena tower, north of Mosta and southeast of Valletta. Above it lies the distinctly softer Globigerina Limestone, which forms the principal outcropping series in Malta. Easily eroded, it produces a gently undulating topography but weathers to a soil of only moderate fertility which is nevertheless responsive to intensive and laborious cultivation. Of a characteristic golden or pale brown colour, it is an excellent building stone (it can be trimmed by hand adzes when newly quarried, but hardens on exposure) and many buildings on the island are made from it.

Next in succession comes an irregular layer of Blue Clay, which is a composite formation of blue and yellow clays and marls. Though absent in certain areas because of thinning out of the beds, this layer is extremely important to Malta in that the clays are impermeable and hence provide a water table between largely

BLAU—CAMERA PRESS—PIZ FROM PUBLIX

LIMESTONE ROCK AND TERRACED PLOTS, WHERE SHALLOW SOIL IS HELD TOGETHER BY RUBBLE WALLS, ON THE ISLAND OF MALTA

permeable limestones. The Blue Clay is also extremely fertile and although its outcrops are greatly restricted they are usually marked by intensive terrace cultivation. The Greensand is a relatively narrow band (less than 50 ft. thick) of reddish-brown or green-brown limestone and, at its junction with the Blue Clay, landslips as well as springs are a feature. Lastly, the Upper Coralline Limestone occurs as a cap about 500 ft. thick upon the higher hills or where downthrow has occurred, and is thus exposed mainly in the west and north. It produces a classic karstic topography of bare rock pavement, eroded joints, solution hollows and irregular pinnacles and outlines.

There are thus marked differences between the eastern and western coasts of Malta. The western coast is high, bold and largely harbourless. On the east local downwarping has produced the remarkable double sea inlet of Grand Harbour and Marsamxett (Marsamuscetto) with nine associated creeks, including those of Sliema, Lazaretto, Msida and Marsa. Between them runs a central tongue of high ground, Mt. Sceberras, upon which the city of Valletta (*q.v.*) is built. The extreme north of Malta is mostly a craggy, bare region of coves and irregular hills separated by a few fertile lowlands. The centre and south is an area of gentler and

AUTHENTICATED NEWS

AERIAL VIEW OF VALLETTA WITH FORT ST. ELMO AT THE EXTREMITY OF THE PROMONTORY, FLANKED BY GRAND AND MARSAMXETT HARBOURS

more cultivated landscapes. The faults and warping movements are of very late geologic age, and the fact that certain Neolithic trackways disappear abruptly into the sea suggests earth movement in some localities even within the last few millenniums.

Gozo has a block structure, with a tilt toward the northeast, and local small-scale faulting and downwarping. There is the same rock succession as in the main island, Lower Coralline Limestone in the south and east producing cliffs rather similar to those in western Malta itself.

There are no perennial streams or permanent lakes in Malta, but because of the extent of bare rock pavement there can be considerable wash of rainfall, and this is important as a cause of soil erosion. Problems of water supply are acute. In most of Malta (especially in the south and east) porous limestone continues below sea level, so that deep wells are liable to contamination by rising salt water; this is a growing problem round Valletta.

Climate.—In general, Malta exhibits the normal Mediterranean pattern of mild, wet winters and hot dry summers. However, as an island in an extensive sea basin, it is windier than many adjacent mainland areas, and only one day in ten is calm. Nearly one day in three the *majjistral*, a relatively cool northwesterly wind, agreeable in summer but raw and damp in winter, prevails. Other winds are the gregale, a dry, sometimes violent and blustery northeaster; the *xlokk* (sirocco), hot and humid from the southeast; the *tramontana*, northerly and cold; and the *nofsinar*, hot and intensely dry from the north African deserts. Because of the rapid changes of air mass over the central Mediterranean, wind and weather can vary considerably within a very short period.

Again because of Malta's maritime situation, the temperature is remarkably stable, although it occasionally exceeds 38° C. (100° F.) in summer. At Valletta monthly means range from 12° (53°) in January to 25° (77°) in July and August, with an average amplitude of 4.5° (8°) in winter and 6.7° (12°) in summer. Inland there are mean differences of up to 3.3° (6°), and patches of ground frost sometimes occur. There is no real thermal dormant season for plants, although growth can be checked briefly by abnormal cold spells and summer heat can cause wilting.

Nearly 70% of the annual rainfall (20.54 in. at Valletta) falls

during October–March (50% during November–January). June and July account for only 2%, July usually being entirely rainless. Rainfall can vary considerably, however, both in overall amount and in onset. For short periods it can be extremely heavy, causing soil erosion and running off rapidly to be lost in the sea.

High humidity means that summer conditions, especially near the coast, can be oppressive. Moreover, conditions of wind, temperature and humidity together often have a markedly deleterious effect on plant growth. Thus, although the annual rainfall appears adequate for agriculture, its value is reduced by the summer drought, irregularity of fall, high evaporation and rapid runoff. Much attention has been given to methods of water conservation. There are ancient works still in existence, with several aqueducts, now only partly used. Great ingenuity is shown in trapping and storing rain water. Many programs were put forward in the 20th century, and important reports were made on the hydrology of Malta in 1952 and 1960. Small projects have been undertaken, but money has not been available for large-scale works.

Soils.—Because of high temperatures and the lack of regular drainage, soil formation in Malta has been slow; hence deposits are generally thin and immature. Moreover, most of the land in Malta and Gozo has been terraced, with high retaining walls and level patches cut from bedrock. When building takes place all soils must, by law, be removed from the site for use in agricultural areas; level stretches within quarries are often covered by such carted soil. Much organic town refuse is also spread on the surface. Consequently, soil in Malta has unusual characteristics; it is almost an exotic, partly manufactured medium. Soils of a *renzina* type tend to predominate, true *terra rossa*s being much less widespread.

(W. B. FR.)

Vegetation.—The rocks and soils are mainly calcareous and the vegetation is typically Mediterranean. The largest element of the flora consists of species that also occur in Sicily and Italy, together with some found in the Iberian peninsula and north Africa. No forests are developed on the islands. The commonest tree is the carob, native to the islands; other native trees and shrubs include the fig and the chaste tree. Maritime and sea-shore vegetation is well developed; typical are golden samphire, rock samphire, saltwort, sea campion, spurge and marram grass.

(V. H. H.)

Animal Life.—The mammals native to Malta are limited to the water shrew, white-toothed shrew, greater and lesser horseshoe bats, pipistrel, large and lesser mouse-eared bats and the least weasel. Rabbits, rats and mice are present as introduced animals. The few resident birds include the blue rock thrush, spectacled warbler, Manx shearwater, Cory's shearwater and jackdaw. Others breeding in Malta are several kinds of owls (including barn, tawny and little owls), linnets, buntings and the rock dove. Since the islands are on a migration route between Europe and Africa, there are numerous passage migrants, including bee eaters, rollers and hoopoes, osprey, vultures and eagles, swallows and cuckoos.

Because of the small size of the islands and the poorness of the vegetation the insect fauna is limited but includes cockroaches, beetles, plant bugs, grasshoppers, flies, dragonflies, moths, bees, wasps and ants. There are, however, several species of butterfly, notably the cabbage white which often arrives in swarms in spring and autumn from north Africa. Locusts also reach the island from Africa, and large numbers of ladybirds frequently arrive in spring from Sicily.

(MA. BU.)

ARCHAEOLOGY

There is no conclusive evidence for Paleolithic man in Malta; the identification of two teeth from Ghar Dalam as those of Neanderthal man is doubtful and they do not seem to have been found associated with the rich Pleistocene fauna of hippopotamus and elephant in the cave. The same site, however, produced shards of pottery which represent the earliest Neolithic colonists of the island, related to those from the Mgarr temple (*see below*) and to the Stentinello type in Sicily. Similar pottery occurs in the earliest Neolithic levels of the Arene Candide cave in Liguria. But

the most notable evidence of prehistoric man in Malta is afforded by the monumental stone buildings usually known as temples and by the huge rock-cut collective tomb or hypogeum at Hal Safieni. The best preserved of the temple structures are at Hal Tarxien, Hagar Qim, Mnajdra and Mgarr in Malta and at Ggantija on Gozo; less striking remains of similar buildings exist at Borg in Nadur, Kordin, Skorba and elsewhere.

The temples are built of the local limestone, though fine Globigerina Limestone was sometimes brought from several miles away, especially where fine-dressed surfaces or decorative carvings were desired. The plans of the buildings are based on the theme of apsidal chambers, usually in pairs, opening from an axial passage or central court, and the whole complex is enclosed in a massive stone revetment, roughly oval in plan, with a concave façade and forecourt at the entrance. The evidence implies that most of the apsidal chambers were roofed by first carrying several courses of corbeled vaulting above the slabs forming the walls and then laying large flat capstones across, but it is uncertain whether some of the very large chambers (e.g., at Mnajdra) were in fact roofed in stone, as the large span presents great technical difficulties, and it is likely that the courts giving access to the chambers were always open to the sky, though in both instances temporary coverings of hides or textiles could have been used. The standard of building, with its fine dry jointing and carefully dressed surfaces, is of high technical quality, and in certain of the temples, probably relatively late in any sequence of construction, there is elaborate surface decoration of low-relief carving (either as naturalistic animal friezes or as spiral patterning) or of close-set pitting apparently made with a drill. Although all the freestanding temples are now ruined and roofless, the interior detail of the rock-cut chambers at Hal Safieni and models of temples or their façades from Mgarr and Hal Tarxien give evidence for reconstructing the roofs on the lines suggested.

In addition to the low-relief carving, there is a large series of figures carved in the round, usually representing obese females and ranging from specimens a few inches high to a statue (of which the lower part alone survives) of a woman in a flounced skirt at Hal Tarxien which is well over life size; at Hal Tarxien too is an enormous bowl carved out of solid stone. There is evidence that much, if not all, of the carving and ornament was originally painted, and at Ggantija traces of interior wall plaster with red paint on it were recovered. In the Hal Safieni hypogeum, elaborate spiral patterns are painted in red in certain of the chambers.

Although the hypogeum was certainly used for a vast series of collective burials, its function need not have been wholly or primarily sepulchral, and there is no evidence that the temples were used primarily for burial. However, their affinities in architecture and in planning are certainly with collective burial vaults, either rock cut or built above ground of large stones, which are known from many areas in the western Mediterranean and belong in the main to the 3rd millennium B.C. The Maltese temples have yielded a rich series of pottery finds, including the incised white-filled ware of Mgarr, allied to that of Stentinello. There also occur wares with fine ornamentation scratched on them and filled with red or white colouring matter in techniques characteristic of early southeast Italian, Ligurian and south French Neolithic pottery, and this style may in part be an imitation of Italian Neolithic painted pottery—shards of painted ware were indeed found at Mgarr and elsewhere. The latest Neolithic pottery includes volute or spiral patterns and these, especially the similar patterns in stone carving, seem likely to be related to the Minoan world shortly before 2000 B.C. The figure sculpture and animal reliefs again are features which suggest eastern Mediterranean origins. The use of the sling in Neolithic Malta (attested by slingstones) may imply Aegean contacts.

At Hal Tarxien, at a period when the original temple was deserted, a cremation cemetery with many burials was established within the precincts. With the burials was pottery of a style quite dissimilar from that of the earlier sites, and there were also bronze or copper flat and flanged axes and flat riveted knife daggers. The radiocarbon date for this cemetery is about 2000 B.C. This would seem to indicate that Hal Tarxien was deserted before this

date, and this, taken in conjunction with other recent radiocarbon determinations, implies that the whole range of Maltese Neolithic temples and allied structures lies within the centuries c. 2750–c. 2000 B.C.

The Maltese Bronze Age is represented not only by the Hal Tarxien cemetery but also by pottery finds at Borg in Nadur at Bahrija and at other sites in the island. The Borg in Nadur pottery, from a settlement site within a probably contemporary defensive wall across a promontory, is exactly paralleled by the Thapsos red ware of Sicily dated by Mycenaean imports to the 14th century B.C. and later. A shard of Late Helladic III pottery from Borg in Nadur confirms this dating. There are rock-cut tombs attributable to the Maltese Neolithic period at Attard, Busbisija (Mosta), Xemxija and Ta Trapna iz-Zghejra (Zebbug). The pottery relates these tombs to the earlier Neolithic phases. There is a blank in Maltese prehistory after the Bronze Age until the coming of Punic colonists in the earlier half of the 1st millennium B.C. Numerous Punic tombs show the island to have been an important colony; their range of date may extend to that of the Roman occupation.

A remarkable type of antiquity in the island is that of the so-called cart ruts, pairs of parallel grooves worn into the rock and having a span of about 4½ ft. It seems that these ruts could not have been made either by cart wheels or, because of the relatively sudden curves in many of them, by sledges; the best suggestion is that they were worn by a primitive form of "slide car" of a type still surviving in parts of Europe, in which the load is dragged on a pair of poles joined at their forward end (water carried in skins would be a likely burden). At one point the line of a pair of ruts crosses the mouth of a Punic tomb shaft in such a manner as to suggest that the tomb was the later feature; this is the only piece of dating evidence that can be adduced, except that at Birzebbuga another pair runs under a shallow inlet of the sea, showing that some marine transgression has occurred since its use. (S. Pr.)

HISTORY

At one time Malta's megalithic monuments were considered to be the best proof of Phoenician settlement in the islands. Although modern archaeology has established that these were built by prehistoric man, many historians still believe that the Phoenicians sought refuge or settled in Malta at some period of their travels through the Mediterranean. Old historiographers record the existence of scattered remains of alleged Phoenician origin but these have since disappeared. Greek inscriptions, coins and works of art found in the island induced some authors to state that the Maltese Islands passed through Greek hands after the Phoenician period. This theory later found many adversaries who would only admit a strong Hellenic influence over the islands.

In the 6th century B.C. the Carthaginians landed at Malta and several Punic coins and inscriptions seem to belong to this period. Historians write that Carthaginian rule was very harsh and that oppressive tribute was levied. This would explain why, in 218 B.C., the Maltese gave up the garrison to the Roman general T. Sempronius. The Romans granted Malta and Gozo the privileges of a municipium. Cicero refers to the Maltese as *socii*; they coined their own money, had the right of sending ambassadors to Rome and of controlling their own domestic affairs. The islands' prosperity is attested by both Cicero and Diodorus Siculus. The latter writes of the beauty and ornamentation of Maltese houses and remains of palaces and dwellings (notably the Roman villa at Mdina) indicate a high degree of civilization and wealth.

In A.D. 60 the apostle Paul was shipwrecked in the bay which now bears his name, and according to tradition and to St. Chrysostom he converted the inhabitants to Christianity. Publius was "chief of the island" and is said to have become the first Christian bishop of Malta. Outside the walls of Mdina are the Maltese catacombs (4th and 5th century A.D.) which are strikingly similar to those of Rome and which were used as places of burial. Malta was not affected by the Greek schism and remained steadfast in its allegiance to Rome.

Early Medieval History.—On the final division of the Roman

dominions in 395, Malta was assigned to the empire of Constantinople and it seems to have undergone the same fate as Sicily; some historians hold that it was conquered by the Vandals and Goths in the 5th century and reunited to the empire by Belisarius in 533. The Arabs made themselves masters of Malta in Aug. 870, massacred the Greek garrison and sold the Greek population to the native inhabitants. Unable to garrison the island with a large force, the Arabs cleared a zone between the central stronghold, Mdina, and the suburb called Rabat to restrict the fortified area. Many Arab coins, some Kufic inscriptions and several burial places were left by the Arabs; they did not establish their religion but they did give Malta its language, some place names and a few customs. (See MALTESE LANGUAGE.)

In 1091 Count Roger the Norman, then master of Sicily, came to Malta with a small retinue and was hailed as a deliverer by the inhabitants. According to tradition, Roger gave the Maltese their national colours, white and red. Under the Normans the dominion of the church was re-established and bishops were appointed. The Arabs were allowed to remain as vassals until 1245 or 1249 when they were expelled by the emperor Frederick II whose house, that of Hohenstaufen, had succeeded the Normans on the throne of Sicily. Gradually, feudal customs asserted themselves, and from 1192 the islands were granted as a fief to great officers of state or illegitimate descendants of the sovereign.

After the battle of Benevento (1266), Malta, with Sicily, passed to Charles of Anjou. In Ft. St. Angelo the revolt of the Sicilian Vespers (1282) was planned, and beneath the same fort the Angevin fleet was defeated (1283) by Peter III of Aragon, to whom the Maltese transferred their allegiance. The islands suffered under a succession of feudal lords who received Malta as a marquise or countship, and in 1397, at the request of the Maltese, King Martin I incorporated the islands in perpetuity in the royal domains. However, when Alfonso V of Aragon was in urgent need of money, he broke Martin's charter by pledging the islands (1420) to a viceroy of Sicily, Antonio Cardona, for 30,000 gold florins. The Maltese paid the debt, but the islands were given to Gonsalvo di Monroy for the same sum in 1425. A revolt, organized and directed by the commune, against Monroy's rule (1427) led the king to incorporate Malta once more in the royal domains by a charter of June 20, 1428, and the Maltese were given authority to resist any intermediate lord that the sovereign might attempt to impose.

The Normans had improved considerably the political and economic condition of Malta and had raised it to municipal status. The political organization was similar to that of the large cities of Italy: the *università*, or commune, had a great deal of control over internal affairs. It was a representative body essentially constituted to defend the ancient laws and privileges of the Maltese. It had wide powers including the election of its officers, the appointment of judges and the sending of ambassadors to the foot of the throne to treat with the king, as was done in the revolt of 1427; it even taxed itself and its members. It was as liberal and democratic a body as any in Europe in the middle ages.

The Knights of St. John.—The Knights of St. John of Jerusalem, or Knights Hospitallers, having been driven from Rhodes by the Turks, obtained the grant of Malta, Gozo and Tripoli in 1530 from the emperor Charles V, subject to a reversion in favour of the emperor's successor in the kingdom of Aragon should the knights leave Malta, and to the annual tribute of a falcon in acknowledgment that Malta was under the suzerainty of Spain. The Maltese at first challenged the grant as a breach of the charter of King Alfonso, but eventually welcomed the knights. The grand master De l'Isle Adam, on entering the ancient capital of Mdina, swore for himself and his successors to maintain the rights and liberties of the Maltese. The order took up its abode on the promontory guarded by Ft. St. Angelo on the southern shore of Grand Harbour and, in expectation of attacks from the Turks, began to fortify the neighbouring town called Birgu (Vittoriosa). The knights lived apart from the Maltese, deriving their principal revenues from estates owned by the order in the richest countries of Europe and accumulating wealth by war or by privateering against the Turks and their allies. In 1551 the African Arabs

ravaged Gozo after an unsuccessful attempt on Malta.

When Suleiman the Magnificent prepared to conquer Malta and exterminate the order, the knights and the Maltese were expecting the attack. The great siege of Malta, which checked the advance of Muslim power in southern and western Europe, began in May 1565. The defenders were outnumbered by about four to one. The sultan placed his troops under the veteran Mustafa and his galleys under his youthful relative Piali; he hesitated to make either supreme and ordered them to await the arrival of Dragut with his Algerian allies before deciding on their final plans. Against Mustafa's better judgment, Piali induced the council of war to attack Ft. St. Elmo, in order to open the way for his fleet to an anchorage, safe in all weathers, in Marsamxett harbour. This proved to be a strategic blunder. In the attack the Turks lost 8,000 killed, besides many wounded, before wiping out the 1,200 defenders. Meanwhile, Dragut was mortally wounded, the attack on Mdina was neglected, valuable time was lost and the main objective, Birgu, and St. Angelo were left intact. The subsequent siege of St. Angelo and its supporting fortifications was marked by great bravery on both sides. Finally, help was sent to the knights from Sicily and Mustafa abandoned the siege on Sept. 8. The order thus reached the pinnacle of its fame.

The grand master, Jean Parisot de la Valette, determined not to impair his independence, refused a cardinal's hat. He founded the city of Valletta with fortifications that were unrivaled.

Throughout the 16th and 18th centuries the knights harassed Turkish commerce and they took part as an allied Christian power in the battle of Lepanto (1571). However, with the growth of wealth and security the martial spirit of the order began to wane and so also did its friendly relations with the Maltese. The civil government became neglected and disorganized, licentiousness increased and riots threatened. In 1722 the Turkish prisoners and slaves, then very numerous, formed a conspiracy to seize the island, but the plot was discovered and promptly suppressed. In 1768 the Jesuits were expelled and their property was confiscated; Grand Master Emmanuel Pinto converted their university into one of general study. Ft. St. Angelo and the fort of St. James were, in 1775, surprised by rebels in a rising known as the Rebellion of the Priests. The last but one of the grand masters who reigned in Malta, Emanuel de Rohan, restored good government, abated abuses and promulgated a code of laws. On his death the French knights disagreed as to the selection of his successor, and a minority was able to elect, in 1797, a German of weak character, Ferdinand von Hompesch.

The rule of the knights ended when, in June 1798, Napoleon took possession of the island. He met with little resistance and after a stay of six days he proceeded with the bulk of his forces to Egypt, leaving Gen. Claude Henri Vaubois in command with 4,000 troops. (See also SAINT JOHN OF JERUSALEM, ORDER OF THE HOSPITAL OF.)

British Rule.—Toward the close of the rule of the knights in Malta feudal institutions had been shaken to their foundations, but the transition to republicanism was too sudden and extreme for the people to accept. Napoleon started despoiling the churches and he seriously interfered with the religion of the Maltese by enacting laws which invaded ecclesiastical and spiritual jurisdiction. Stoppage of trade and absence of work (in a population of which more than half had been living on the foreign revenues of the knights) followed the defeat of Napoleon at the Nile and the failure of his plans to make Malta a centre of French trade.

An attempt to seize church valuables at Mdina was forcibly resisted by the Maltese, and general discontent broke into open rebellion on Sept. 2, 1798. The French soon discovered to their dismay that, behind the rubble retaining walls that crisscrossed their fields, the Maltese were unassailable. The prospect of an English blockade of Malta encouraged the insurgents, of whom Canon Francesco Caruana became the most prominent leader. The Maltese formed a provisional government and an assembly. An appeal was made to Lord Nelson, who sent his Portuguese allies to blockade the island; later the British fleet took over and, after visiting the island, Nelson left Capt. (later Adm. Sir) Alexander Ball in command. On Feb. 9, 1799, the Maltese assembly

appointed Ball as its president and head of government and troops. The British flag was hoisted side by side with the Neapolitan, since Nelson upheld the contention that the king of Sicily (as successor to Charles V in that part of the former kingdom of Aragon) was the legitimate sovereign of Malta. After 14 months British troops were landed and suffered no casualties. Few Maltese lives were lost in actual combat, but famine and sickness killed thousands. Finally, after a siege of two years, the Maltese with the help of their British, Portuguese and Neapolitan allies forced the French to surrender. The treaty of Amiens (1802) provided for the restoration of the island to the Knights of St. John; the Maltese strongly protested against this, realizing that it meant the re-establishment of French influence. The assembly drew up a Declaration of Rights, in the first article of which the king of Great Britain was acknowledged as sovereign of Malta on certain conditions, such as that he should maintain the Roman Catholic religion and observe the constitution to be established by the assembly. Meanwhile, Sir Alexander Ball governed Malta as civil commissioner from 1802 until his death in 1809.

England's refusal to give up Malta was one of the causes of renewed war with France. In 1813 the British government accepted the offer made by the Maltese and acknowledged them as British subjects; the treaty of Paris (1814) ratified the compact. Sir Thomas Maitland was appointed governor and commander in chief in the Mediterranean with absolute powers and he introduced many important reforms. Trial by jury for criminal cases was established in 1829. An advisory council of government, composed of nominated members, was constituted by letters patent in 1835, but this measure only increased agitation for a representative legislature. Freedom of the press was introduced on the recommendations of John Austin and George Cornewall Lewis (later Sir George Lewis), royal commissioners, appointed in 1836. The chief government posts in the civil service were opened to the Maltese, sinecures were abolished, legal procedure was simplified and a police force established on the English model. Richard More O'Ferrall was appointed civil governor in 1847 and in June 1849 a legislative council was constituted with ten nominated and eight elected members. The practice of appointing military governors was reverted to in 1858, but the administration was largely confided to the chief secretary, with real power, at times, in the hands of the crown advocate.

Between 1854 and 1868 the criminal, commercial and civil laws were codified. Much of this work was carried out by the crown advocate, Sir Adrian Dingli (later chief justice and president of the court of appeal). An executive council was established in 1881 and the franchise extended in 1883.

In the 1880s an attempt to carry out measures prejudicing the privileged status of the Italian language in the island met with stiff opposition from Fortunato Mizzi, a lawyer, and his Nationalist party. Count Gerald (later Lord) Strickland joined forces with Mizzi and together they succeeded in obtaining the constitution of 1887, which established a legislative council consisting of 14 elected and only 6 official members. All those elected, including Strickland, were supporters of Mizzi's party. After a few months Strickland accepted a government post, and in 1889 he was made chief secretary. During the 1890s there was widespread agitation over the laws respecting mixed marriages, the Maltese relying on the Roman canon law, part of the law of Malta, and the English on the common law of England. The Holy See was consulted on the subject, but the question could not be settled to the satisfaction of both parties. In 1898, on opposite sides of the table, Mizzi and Strickland headed violent disputes in the legislative council on the language question, taxation and other subjects. The duel culminated in a council motion, passed by the elected majority, asking for the removal of Strickland from office. In 1902 he was made governor of the Leeward Islands. Mizzi would not yield on the language question and when the constitution was repealed in 1903, bureaucratic government with an official majority was again fully re-established for all local affairs.

During World War I the Maltese provided a garrison for the island and many naval seamen, as well as labour battalions for service at Gallipoli and Salonika. Postwar economic difficulties

and agitation for constitutional reform led to violent rioting in Valletta on June 7, 1919. A national assembly was constituted similar to that set up in 1798, and a draft constitution was drawn up. In 1921 a constitution based upon the dyarchical principle was granted by letters patent. Members of the senate and house of assembly were to be elected by proportional representation, debates might be conducted in English, Italian or Maltese, but all official entries were to be in English or Italian. English was declared the official language of the administration and Italian the official language of record in the law courts. During the Nationalist administration the two sides of the dyarchy worked with little friction.

After the Strickland ministry took office in 1927, serious politico-religious trouble arose between government and church. The constitution was suspended in 1930, but restored in 1932. The Nationalists were elected to power, letters patent amending the constitution provoked an atmosphere of recrimination and in 1933 a second suspension followed. Then, by letters patent, Italian lost its position as an official language and as the language of the courts. In 1936 the constitution was revoked and full powers were vested in the governor until limited representation without responsibility was granted by the 1939 constitution. A council of government of 20 members was created, 10 being elected, 2 nominated and 8 official; the governor had a casting though not an original vote. The entire arrangement was much like that of 90 years earlier.

After Italy entered World War II in 1940 Malta was subjected to severe aerial attacks by German and Italian bombers based in Sicily. The island, 1,000 mi. from the nearest British position, became vitally important as a base of operations. For three years it was defended by the garrison and the people. At the height of the siege it was possible to send supplies of aviation gasoline and munitions to Malta only by submarine, while additional fighter aircraft of the Royal Air Force were flown to the island from the decks of distant carriers. Food became scarce. Despite the hardships, however, civilian morale remained high. On April 15, 1942, George VI awarded the George cross "to the Island Fortress of Malta to bear witness to a heroism and devotion that will long be famous in history." This was the first time that a medal had been conferred upon any part of the British Commonwealth. The siege ended in 1943: by June 30 of that year 1,436 civilians had been killed, 3,415 wounded or injured and about 37,000 buildings destroyed or damaged. The British government awarded more than £31,000,000 to Malta as compensation for war damage.

Government After World War II.—In 1947 self-government was once more granted to Malta. As in 1921 the constitution was based on the dyarchical system. It provided for a legislative assembly of 40 members elected by proportional representation; suffrage was extended to women; the official languages were to be English and Maltese.
